The hidden side of pipetting

It's not so easy. In chemistry, in microbiology, in biochemistry, pipetting is a speciality.

Dispensing precise volumes with assurance requires the finest instruments and flawless technique.

Only Gilson pipetting systems can guarantee the long-term accuracy and precision you require.

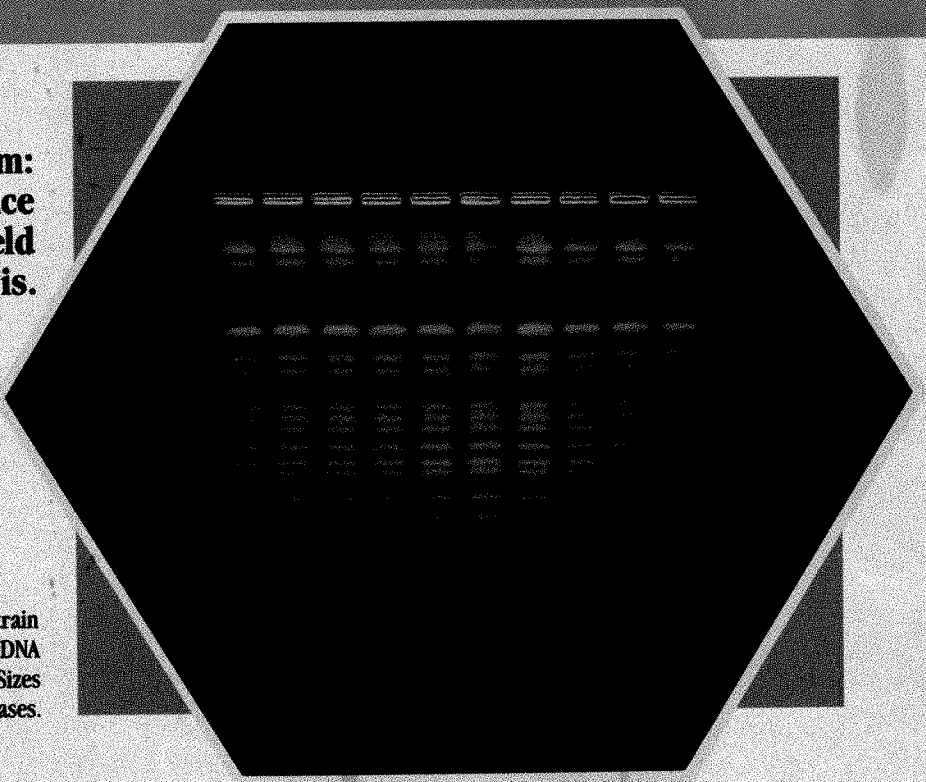
Our pipetting systems are built to be better. When you take a Pipetman in your hand, it feels solid, dependable.

If you look closer, you'll see why.

Inside, you'll find a wearproof piston assembly and resistant seals for constant performance even in a cold room. The entire mechanism functions smoothly, cleanly. No grease, no oil.

Outside, the shock-proof handgrip has a low thermal coefficient. Body heat does not affect the precision of the pipette after prolonged use. And Gilson pipettes are easy to hold stable (for good reproducibility).

Now look at your pipette tip. Gilson tips are manufactured with the same painstaking care as our pipettes.



For more information, please contact your nearest Gilson representative.

Highest resolution of chromosomal DNA

New CHEF-DR™ II System: A major advance in pulsed field electrophoresis.

Yeast chromosomes, strain YNN 295. 16 chromosomal DNA fragments are resolved. Sizes range from 0.2 to 2.2 megabases.

The CHEF-DR II system* lets you resolve DNAs from 200 bases to 10,000,000 or more[1] with sharp bands. This powerful system integrates advanced micro-electronics and electrophoresis technologies to produce straight lanes and an extraordinarily wide range of size separations.

The CHEF-DR II system is the only system available with electronic feedback clamping of each of the chamber's electrodes. The voltage sensing provides uniform fields in the gel at all times, independent of variations in buffer conductivity, sample placement, gel dimensions, or temperature. Consequently, you obtain all the following benefits:

- Highest resolution
- Straight lanes
- Sharp bands
- High sample capacity, up to 30 lanes
- Widest range of DNA size separation
- Reproducible separations

A lot more than equipment comes with the CHEF-DR II system. The comprehensive instruction manual guides you through sample preparation and electrophoresis. We've also included strategies for separating all sizes of DNA. And we also provide in-depth technical support after you begin your pulsed field experiments.

The CHEF-DR II system can extend your horizons in chromosome analysis, mapping, screening, and DNA sizing. Bulletin 1430 brings you complete details, including a comparison of pulsed field techniques and their respective resolving powers.

*Dynamically Regulated Clamped Homogeneous Electric Fields. Patent applied for.

Answers.

hen Your Crystals Won't Wait, You eed the FAST Solution

ST, the Fast Area Sensitive TV Detector ffractometer, certainly lives up to its name. s the most powerful diffractometer system r single crystal structure studies and has al- ady been proven on a variety of biological mples. FAST provides:

high resolution
single photon sensitivity
wide dynamic range
higher counting rates at linear response
highest sensitivity in the energy range 0.5 Å to 3.5 Å .
real-time and digital imaging.

ST is available as a completely integrated nkey system with a MicroVAX computer. e package includes an advanced range of w features.

Strong X-Ray Sources - No Problem!

FAST can be supplied as a ready-to-go system with our new rotating anode X-ray generator. Because FAST easily accepts the high intensities of strong sources without dead-time losses, this forms an ideal system for applications where the range of intensities is extremely wide.

Furthermore, typical intensity ranges from synchrotron sources can also be easily accommodated.

New Data Acquisition Software

Completely new data acquisition software has been developed in cooperation with leading experts in the field to make optimum use of FAST's advanced hardware.

New Color Graphics Imaging

The color graphics feature provides powerful dynamic imaging including the display of intensity thresholds.

A Convenient, User-Friendly System

As you would expect from the world-leader in single crystal X-ray diffractometry, FAST is extremely easy to use. The operator can start productive work immediately with the user-friendly, menu-driven system.

Worldwide Support Network

Of course, all Enraf-Nonius products are backed by a worldwide support network, ensuring fast and efficient service in all countries.

"Ask for the detailed brochure!"

Water – the perfect medium for DNA replication

Autogene is the new water bath from Grant for rapid temperature cycling.

Rather than dry heat, it uses water – because this is the perfect medium for heat exchange. Water warms and cools rapidly and evenly because it completely surrounds anything immersed in it. This allows the rapid and efficient heat transfer which is so important in DNA replication.

Autogene has been developed from Grant's considerable experience in modern water bath technology. It is therefore backed up by Grant's traditional commitment to quality and reliability which means the extra peace of mind of a three year guarantee.

Autogene is flexible and versatile, and benefits from the following features:

- Temperature range 0°C to 99°C
- Maximum heating rate 1°C/2.5 seconds
- Maximum cooling rate 1°C/3 seconds
- Uniformity of temperature ± 1°C
- Max hold time 99.9 minutes
- Tap water/refrigerated cooling
- Holds different tube sizes and microtitre plates

Grant has a worldwide network of distributors, so wherever you are contact us today for more information.

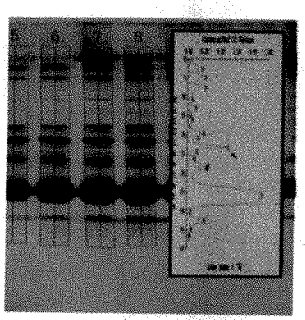
IF YOU MISS PART OF THE PICTURE, YOU COULD MISS THE POINT.

If you start out missing details, or limiting software applications, you can end up missing the point of an electrophoresis image analysis.

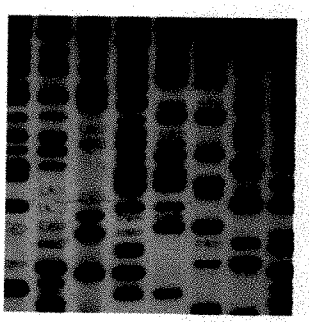
Whether you work with 2-D gels, 1-D's, Blots or RFLPs, you crunch more data and support more applications with VISAGE™ Image Analyzers.

You'll get accurate quantitative results without the limitations of MS-DOS architecture, or the shortcomings of PC-quality monitors. And you get the flexibility of supporting many different applications.



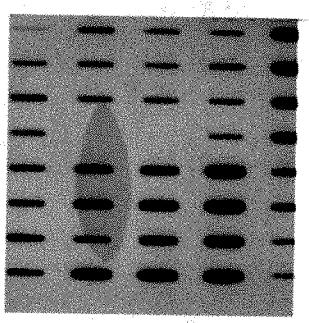
We build our systems around UNIX 32-bit workstations. UNIX gives you true multi-tasking and superior networking. Even the largest images from laser densitometers can be analyzed quickly. High-resolution, grey-scale monitors let you verify results with your own eyes, and zoom images to see the smallest detail.

With VISAGE, the ability to add applications as upgrades will put a smile on your face. Simply add the software for a new task such as RFLP, and it's like having a whole new system.

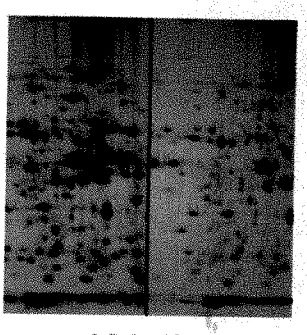


And whatever system you start out with, VISAGE software is fast and fully automated. No manual data entry or manipulation are needed.

Find global changes in a series of 2-D gels with powerful relational databasing tools.



Go from raw data to Allele Frequencies on RFLPs with automatic feature detection and comparison programs.



1-D Analysis

Whole Band 1-D Analysis

Blot Analysis

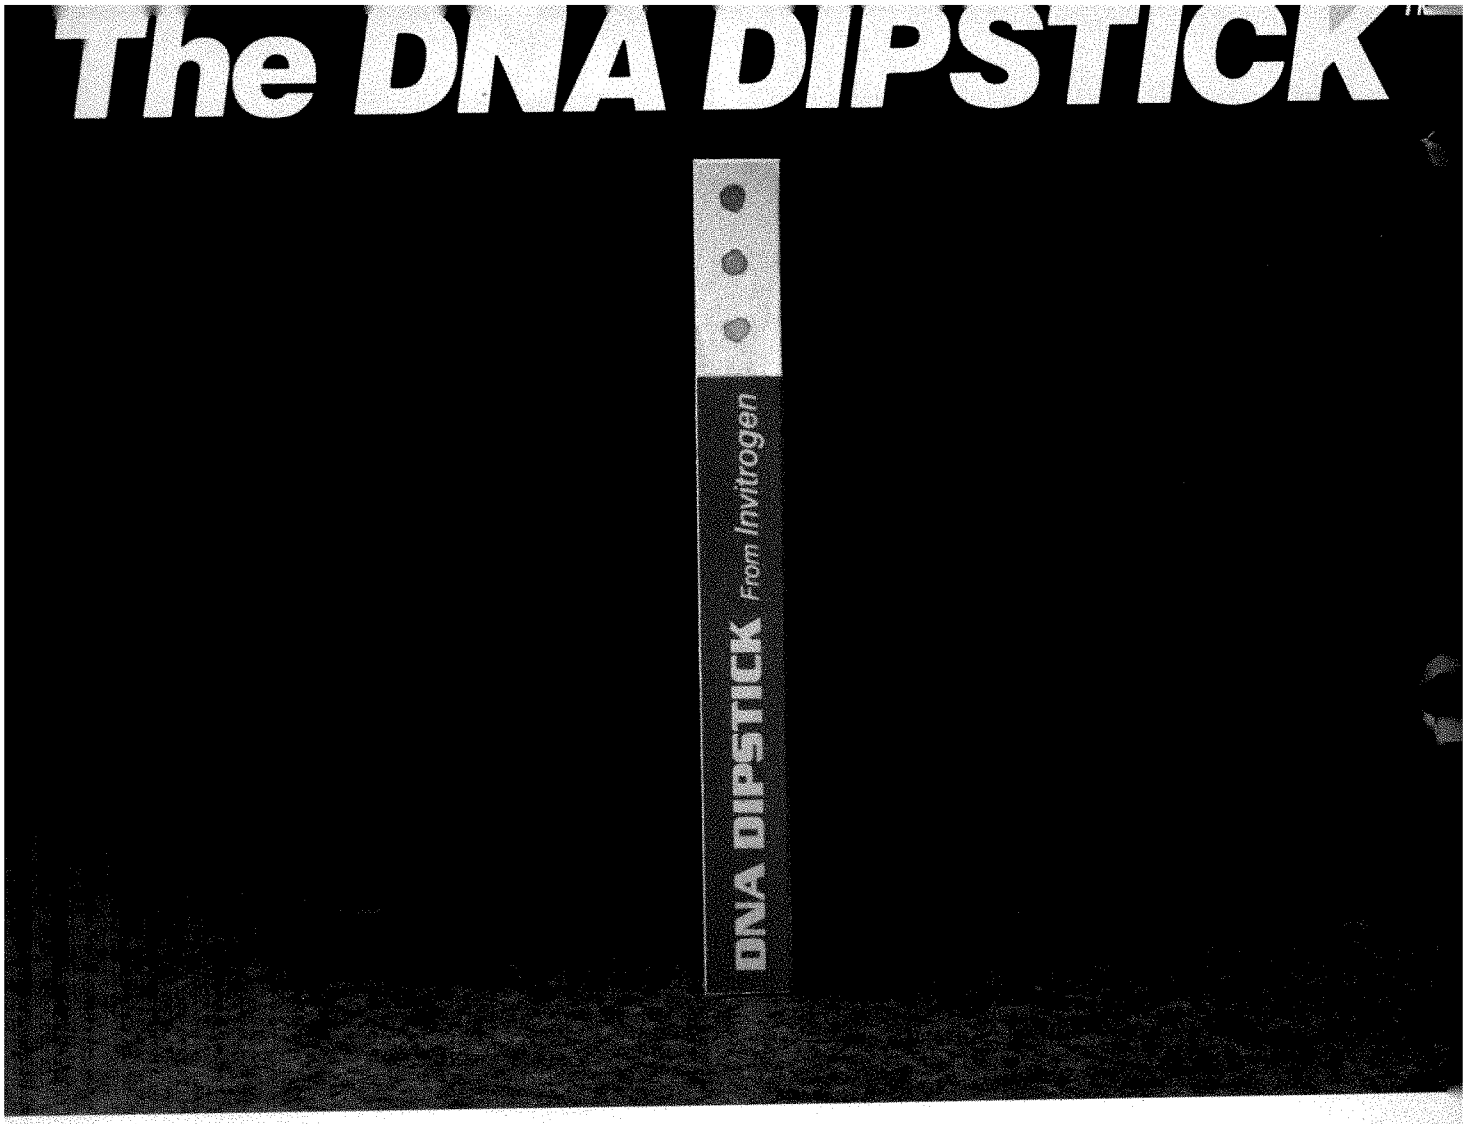
2-D Analysis

Generate comparative data between blots or features within a blot.

Apply a set of standards over many 1-D separations for high throughput QC applications.

For image acquisition, choose from Kodak high resolution CCD cameras in 512 or 1024 formats, or the latest in laser densitometry. Only Bio Image offers you the best of both worlds.

Get The Complete Picture Today



Call your Bio Image representative at 800-624-5394 and find out how you can get a complete VISAGE system for less than $30,000. In Michigan, call 313-971-7500. Ask for a demonstration in your lab. In the meantime, call for literature. Or write Bio Image, 1460 Eisenhower Place, Ann Arbor, Michigan 48108.

The DNA DIPSTICK

Makes Quantification Fast & Simple!

Invitrogen Introduces a Fast, Simple, Non Radioactive Method For Quantification of Nucleic Acids with The DNA DIPSTICK.

- Quantitates Nucleic Acids at Concentrations as Low as one Nanogram per Microliter

Quantification Doesn't Get any Easier

- Provides a Permanent Record of Results
- Is More Consistent Than Conventional Techniques
- Requires no Special Equipment for Fast Inexpensive Results
- Ideal for Quantification of single or double stranded DNA, RNA or oligonucleotides

Now you can have fast, accurate nucleic acid measurements which are critical for PCR Amplification, Subcloning, DNA sequencing, and cDNA or Genomic DNA Library Construction.

Because time and accuracy are very important in today's rapidly changing world, Invitrogen is committed to providing DNA Technology that is as advanced as it is simple.

To order, ask for catalog #K5632-01.

TRUL[illegible] [illegible]EACTIA[illegible]

FULLY PROGRAMMABLE DRI-BLOCK® TEMPERATURE CYCLER PHC-2

This latest programmable Dri-Block® temperature cycler PHC-2 has a powerful microprocessor programming capability yet is designed for simplicity of operation. It is now possible to link programmes, hold temperatures for long periods choose four ramp rates up and down and recall temperatures and times from the PHC-2 memory. Two models are available for use with either 0.5 ml or 1.5 ml microcentrifuge tubes.

- Temperature range 0°C–99°C
- Fast temperature change
- Wide and variable number of segments, programmes and cycles – limited only by memory capacity.
- Four user selectable up/down ramp rates
- 99 hour maximum hold time
- Remote sensor in dummy tube to read sample temperature and initiate programme timing.
- Block uniformity 3°C
- RS232 outlet/centronics printer output
- 54×0.5 ml or 24×1.5 ml microcentrifuge tubes
- Water cooled with separate connection for end of programme below ambient cooling
- Temperatures and times held in memory for recall to screen or printer

PHC–1

For less sophisticated programming requirements the alternative model PHC-1 is a simple to use heat/cool unit providing a repeatable cycle of up to three independent temperatures and dwell times. A standard aluminium block will accept up to 54×0.5 ml capped microcentrifuge tubes.

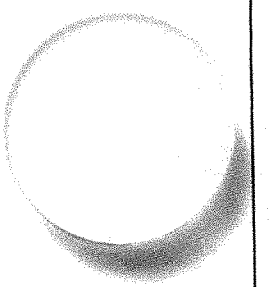
Natural type 2A diamonds.

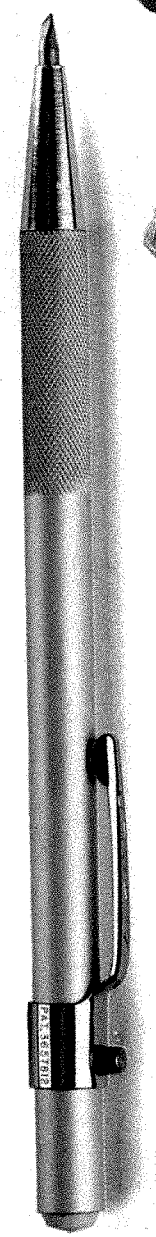


Drukker is a world renowned specialist in scientific applications of diamond, pioneering new manufacturing techniques and fields for its use.

Diamond at the cutting edge.

1250 x magnification photos of an unused diamond blade (left) and an unused steel razor blade (right).

A 3mm diameter infrared window for less than US$ 300.



Type 2A diamond transmits light over an extremely wide spectral range.

Diamond is extreme...

- in hardness ..... Mohs 10
- in strength ..... 10000 N/mm^2
- in transparency range ..... 230 nm to 100 μm +
- in thermal conductivity ..... 2000 w/m.K at 300 K
- in chemical inertness ..... to everything below 700 K

But not in price!

A hand-held fiber optic cleaving knife below US$ 120.

Other knives are available to OEM's of cleaving tools. All are extremely sharp and can yield optically clean surfaces.

A heat sink, 1/2 mm square, can cost below US$ 10.

Natural diamond heat sinks (type 2A) are available in the following standard sizes.

□ or ⌀mm	Thickness mm					
0.2	0.1	0.25				
0.25	0.1	0.25				
0.4	0.1	0.25	0.4			
0.5	0.1	0.25	0.4	0.5		
0.75	0.1	0.25	0.4	0.5	0.75	
1.00	0.1	0.25	0.4	0.5	0.75	1.00

Diamond heat sinks are also available embedded in copper packages or mounted on copper substrates.

Our standard product range also includes diamond substrates, spacers, prisms, anvils, scalpels, probes, logs and styli, which can be mounted or metallized as appropriate. If you have a requirement for which the properties of diamond seem suited, we can advise you on the feasibility. You could be pleasantly surprised at the low price. For more information on any of the products mentioned contact us.

Advances in Electrophoresis

This long-awaited new serial aims to provide critical reviews of selected techniques or important areas of application of electrophoresis. Rath-er than summarizing all available information, the reviews present the essence of each topic and demonstrate its potential. The reviews appeal to the great many readers who use electrophoretic techniques but do not follow systematically their development in the original literature. This publication is indispensable to those interested in the application of new techniques or entering a field requiring the use of electrophoresis.

From reviews of the first volume:

"...the volume is certainly of high quality and will prove its value to workers in electrophoresis..."
Journal of Chromatography

"...an excellent book containing a number of most valuable reviews of high quality...
...indispensible to all who need to know about and use electrophoretic techniques...
Trends in Biochemical Sciences (TIBS)

...an excellent addition to the bookshelf of workers both new to, and specializing in, the application of electrophoretic methods..." *Bio/Technology*

"...will be invaluable in the laboratory, because of its extensive discussion of techniques used in almost all laboratories... *Biochemical Education*

...fills a definitive need for an authoritative and timely source of information on electrophoretic techniques... *Analytical Biochemistry*

Volume 1

Edited by A. Chrambach, M. J. Dunn and B. J. Radola
1987. X, 441 pages, 130 figures and 24 tables. Hardcover. £ 56.00. ISBN 3-527-26741-7

Contents: Two-dimensional Polyacrylamide Gel Electrophoresis, *M. J. Dunn.* Detection of Proteins Separated by Electrophoresis, *C. R. Merril.* Protein Blotting: A Tool for the Analytical Biochemist, *J. M. Gershoni.* Electrophoresis of DNA in Agarose and Polyacrylamide Gels, *N. C. Stellwagen.* Affinity Electrophoresis, *K. Takeo.* Recent Trends in Capillary Isotachophoresis, *P. Gebauer, V. Dolnik, M. Deml* and *P. Bocek.*. Preparative Polyacrylamide Gel Electrophoresis of Proteins, *R. Horuk.*. Red Cell Enzyme Markers in Forensic Science: Methods of Separation and Some Important Applications, *J. G. Sutton.* Index.

Volume 2

Edited by A. Chrambach, M. J. Dunn and B. J. Radola
1988. X, 456 pages, 120 figures and 33 tables. Hardcover. £ 62.00. ISBN 3-527-26964-0

Contents: The Current State of Electrofocusing in Immobilized pH Gradients, *A. Görg, J. S. Fawcett and A. Revolution, but without change

The British government is again brooding about its mechanism for supporting basic science. The best solution is radical change without the appearence thereof. The danger is the inverse.

THE British government and its science establishment do not have long to decide what will be the future pattern of research support. By the end of this year, the government needs to be able to say what arrangements there will be for the financial year beginning fifteen months later; will there be five autonomous research councils, as at present, or only one? The question need never have arisen, and did so only accidentally; an urbane but otherwise impatient industrialist, Mr J. R. S. Morris, was appointed a year ago to adjudicate on a turf dispute between the research councils responsible for basic science and medical research (the disputed ground was biotechnology), but the terms of reference were so appropriately genteel that Morris (he had four colleagues as well) was virtually free to advise on what he chose.

It is no surprise that Morris discovered that science is a seamless web, that all partitions of science are bound to be illogical and that it would be better to lump everything together under one larger research council with a universal remit to support research. But the Morris report is more cogent than that. These days, there is a surprizing concentration of research at the boundaries between the interests of the five research councils. This is not mere accident, the way an ancient cookie crumbles, but a sign that, beneath often forbidding exteriors, all the research councils compete more vigorously with others than with themselves. Operationally, an interesting interdisciplinary research proposal is bound to seem more appealing than another written straight down the middle of a well-trodden road. The case for returning to a less adventitious pattern is strong, but not sufficient in itself.

The most conspicuous danger in a further reorganization of the means of supporting basic research in Britain is typified by the results of the endless fine tuning of the past quarter of a century. Every few years, some committee or another reaches the conclusion that logic requires a slightly different way of doing things, some energetic minister listens and then effects a change approximating the committee's recommendations — and a few more handfuls of creative people are prematurely put out to grass or, worse, required by their terms of appointment to work on problems that do not interest them. Surely it must now be plain that the scientific community in Britain has had as much of that as it can stomach. The Morris recipe should stand or fall by whatever extra it can offer.

The most important need in Britain now is that a few handsful of very young and very able people whose ability is widely recognized should be able quickly to accumulate the resources (cash and people) required for outstanding original work. Putting all five research councils in the same building and giving them the same letterhead will not make such a state of grace more probable. Sadly, for tidy administrators, there is no single formula under which grants for people such as these can be dispensed. But there also needs to be a measure of continuity: no purpose would be served by giving the whole research enterprise the impression that it has served its purpose. That argues for a weasel's answer to the Morris question; give all the research councils the same letterhead, but take more than 10 per cent and less than 25 per cent of their money away, to be spent quite differently. And, given the fragile condition of morale, the simplest way of effecting that is to pretend that there is to be no reorganization at all, but that the supervisory body called the Advisory Board for the Research Councils will be given executive powers (and the right to spend money) as well as the responsibility for designing the letterhead. □

Nuclear cooking-pot

Unless a major power (or several) intervenes, the Middle East will be a nuclear-weapons playground in ten years.

WHAT can there be in common between the discovery that a branch of the Italian Banca Nazionale del Lavore (BNL) in Atlanta, Georgia, has been issuing unauthorized letters of credit to manufacturers in the West and a TASS report that a long-range missile was fired last Thursday from a point near Jerusalem into the sea off the coast of Libya? To be truthful, nobody can tell for sure. But if the events, either together or separately, sustain some of the interpretations that are being put upon them, not merely those who live in the Middle East but the rest of us too will be much worse off.

BNL's Atlanta branch is not there to compete with indigenous banks for people's checking accounts, but to lubricate the wheels of international commerce. Letters of credit are one way of doing that; people signing contracts to buy something, but wishing to defer payment, will ask their bank to vouch that the funds will eventually be paid, whereupon the seller can often raise the money

right away. The trouble, at Atlanta, is that an employee of the bank issued letters of credit amounting to more than $2,000 million to agencies of the government of Iraq without his employers knowing. Iraq is of course the paper victor in the long Gulf War with Iran, and has to replenish its military equipment; the names of the companies in whose favour the letters of credit have been drawn are suggestive of that. But Iraq has also plans to build a long-range missile, and may be buying (or hoping to buy) the necessary components.

So too, of course, does Israel. That the most embattled country in the Middle East should be equipped to defend itself against strategic attack is legitimate enough. But at 1,500 kilometres — the range at which both Iraq and Israel strive — missiles do not make sense as tactical battlefield weapons, because they are insufficiently accurate. Prudent generals will therefore insist that, with missiles of such a range, only nuclear warheads can make sense. They will do so in the process of convincing themselves that deterrence is a way of preventing wars and not of winning battles.

That is where, for the rest of us, the bad news appears. Even generals have to make housekeeping calculations. Would it be better to spend the money on, say, Kalashnikov automatic rifles, or on the means of building and launching 1,500-kilometre missiles and the nuclear warheads to go with them? Hitherto, most generals have acted conservatively, although it is so probable as nearly to be certain that Israel already has a substantial stock of nuclear warheads. Iraq, by contrast, is a long-standing member of the Nuclear Non-Proliferation Treaty (and thus is still rightly indignant that its research reactor should have been illegally attacked by Israel in 1982). Now, with the help of a paper-pusher in Atlanta, it has created the illusion of being a big player. But what if the illusion conceals an identical reality? *Ceteris paribus*, as the economists say, there will be at least two overt nuclear powers in the Middle East ten years from now.

That should keep most of us from our beds at night. A nuclear Middle East would be the Lebanon, as now, writ large. Nobody, especially not those most concerned, would benefit. But how to avoid the prospect? It would help if there could be a conference on the Middle East, but Mr George Bush seems to prefer staying at home and Mr Mikhail Gorbachev has little choice, so that the mayhem in the occupied territories will continue. The International Atomic Energy Agency, run by a Board of Governors representing the world establishment (which meets next week) might exert its influence, but will not. The best way of avoiding real trouble would be for India and Pakistan — whose present leaders are well-disposed towards each other and the future except when one or the other faces trouble (an election or just fractious opposition) — should make a nuclear-weapons deal. Otherwise, there is a danger that the long-withheld promise of a comprehensive test-ban treaty between the open nuclear powers, the best way forward at Geneva now, will simply be overtaken by events. □

Tunnel to nowhere

The British government's neglect of transport's to Eurotunnel may be a deliberate ploy.

ONCE upon a time, there were inveterate enemies separated from each other by a narrow strip of water called the English Channel, who liked to fight each other at every opportunity, at places with mellifluous names such as Agincourt (the 'g' is soft, as in the middle consonant of 'Brezhnev'). But after many battles and with the passage of time, even these considerable warriors became sated with their victories. (Both had a flair for not remembering, or even recording, their defeats.) So one of them went to Rome to sign a treaty to engage in equal and free trade with its neighbours while the other declined the invitation; everybody sighed with relief, believing that their quarrelsomeness would for ever after be directed against quite different enemies.

Sadly, the outcome has been otherwise, but for a curious reason: most people know geography, but hardly anybody understands it. Living on an island is a splendid state of grace if you believe that everybody else would also like to live there — and if you know they cannot make the journey. But if you have reason to believe that other people do not share your fondness for island life, you quickly discover that island life is a recipe for isolation. The fairy story accounts for British vacillations about the European Community over the past forty years.

More recently, there has been an even more curious happening. The British and French governments, each with ten centuries of recorded history at its back, have come to recognize that people could (and did) cross the English Channel on foot not much further back in time (say, 10,000 years ago). Mindful (as UN communiques say) that the English (as they were then called) were seized by the fear, at the height of the Napoleonic Wars, that the French might dig a tunnel and walk beneath the Channel, they agreed to exorcize the nightmare by building a tunnel in the full glare of publicity; they would send television cameramen down the tunnel at every opportunity, and would not pay for it themselves, giving its operators a chance to make money from it instead.

Only then did an odd thing come to light: the English, having agreed that there should be a tunnel free for all to use, neglected to make arrangements for conveying people or their possessions from the end of the tunnel to whichever places they wished to go. The British government has agreed to convert about 20 kilometres of country lane near Ashford, Kent, into a modern highway, but has otherwise said that people whose ambitions extend beyond the end of the tunnel must either create their own means of travel or wait until 1995, when there may be a fast railway link if only private entrepreneurs will build it (which is unlikely). It is Agincourt all over again. People from France will be exceedingly irritated, but nothing much in England will have changed. □

NIH restricts university links with industry

- Ban on stock owning
- Too easy to waive rules?

Washington

UNDER pressure either to deal sternly with conflicts of interest in research or to have legislation to that effect imposed on it by Congress, the National Institutes of Health (NIH) last week proposed new guidelines for the conduct of research supported by both private companies and federal funds. Setting the scene for a heated debate ahead, researchers quickly responded that the proposals are too rigid, while Representative Ted Weiss (Democrat, NY) said they give universities too much freedom.

The NIH guidelines, drawn up with the Alcohol, Drug Abuse and Mental Health Administration, impose three prohibitions on institutions receiving NIH funds. No one in a key research or management role may hold equity or options in "any company that would be affected by the outcome of the research or that produces a product or equipment being evaluated in the research project". Neither researchers nor any other "key employee" may receive honoraria, fees or a management position from a private company if they are involved in a federally-funded project that is evaluating the company's product. And no information can be shared with "any company with which a conflict exists" until the information is made publicly available.

The guidelines also stipulate that when researchers receive both private and federal funds, all private support, including instrumentation, consultancies and honoraria, must be disclosed in applications to the NIH and to the institution, and any potential conflict of interest must be resolved before an award is accepted. They also require the institution to ensure that "private companies are not in a position to influence the research plan, results or the reporting or interpretation of results".

Grants awarded through the small business innovation research (SBIR) programme will be exempt from the guidelines the programme was mandated by Congress specifically to increase federal research funds for small businesses.

Weiss, chairman of the House subcommittee on human resources and intergovernmental relations, welcomed the "strong minimum standards", but criticized the "numerous vague waiver and exception provisions which are left to the discretion of the universities". Institutions may grant waivers to the proposed rules if, for example, they decide that the equity holdings are so insignificant that they could not influence research results or the direction of research. NIH leaves institutions to decide what amount of equity might be considered insignificant.

But Weiss maintains that restrictions should be applied equally. "To allow universities the freedom to determine when stock ownership or honoraria present conflicts of interest would be untenable," he said.

NIH recommends that panels set up to review disclosures and waivers should include one member from outside the institution. All waivers must be reported to NIH, which may allow a conflict of interest to persist if it is in the best interests of the public and of the NIH. But these provisos do not reassure Weiss, who says that "many universities are blind to potential conflicts of interest among their own faculty and will probably rely heavily on exemption provisions".

Universities are unlikely to welcome the proposals. At a two-day symposium on conflict of interest hosted by NIH in June, it became clear that they would resent any restrictions imposed arbitrarily from outside (see *Nature* **340**, 7; 6 July 1989). Belle Cole, director of research and public policy at the University of California at Berkeley, criticized the "inflexibility" of the proposals and said that by specifically prohibiting certain situations NIH had "gone further than may have been called for". She said that the onerous reporting requirements of the guidelines would create "a lot of bureaucratic activity".

The chairman of research at the Cleveland Clinic Foundation, Bernadine Healy, said that the proposals were "too vague" and subject to different interpretations. She also said that there would be "a lot of problems" with the prohibition of the release of information to companies before it is made public, as this is usually one of the terms of contracts with industry. And the exclusion of SBIR grant recipients from the guidelines was, she added, "inappropriate . . . and inconsistent with the rest of the document".

But Thomas Malone of the American Association of Medical Colleges (AAMC) said he was "pleased with the approach" NIH has taken. The AAMC and the American Association of Universities are both developing conflict of interest guidelines, said Malone. When these are in place he said, "I'm fairly confident that in the end we'll have a pretty effective system . . . that would offset the need for any legislation". **Christine McGourty**

INDIAN AIDS

Penalties — and help — for victims

New Delhi

LEGISLATION introduced in the Indian parliament last week makes AIDS a notifiable disease, and requires regional health authorities to coordinate counselling as well as treatment for people infected by the AIDS virus. But the proposed law also imposes criminal penalties on any HIV-infected person who knowingly donates blood, semen or organs, and gives the government power to quarantine those with AIDS.

Whether these more stringent actions will be put into practice remains in doubt for reasons of both cost and logistics. Each Indian state will be required to designate a health authority to which general practitioners must report cases not only of AIDS but also of drug addiction. The authority is expected to provide health education, counselling, medical treatment and follow-up for notified HIV-positive cases; drug addicts will also be tested for HIV infection. Also introduced will be mandatory HIV-testing for blood donors.

The state authorities are also empowered to remove any infected person to a hospital or to some other place to prevent that person from becoming a risk to society. The bill provides $10 million for creation of counselling, hospital and rehabilitation facilities.

The criminal penalties in the bill lack one feature recommended by the Indian Council of Medical Research, whose director-general, Dr. A. S. Paintal, had been pushing for more stringent legislation banning sex between Indian residents and foreigners. It is Paintal's belief that most cases of AIDS in India have been, and still are being, brought in by foreigners.

Even before the law comes into force, there are doubts about how effectively it can be implemented. If followed strictly, the new law would require the 1,450 people, mostly prostitutes, known to have AIDS to be rounded up and sent to places of special care or to counselling centres. But no such centres exist.

It is feared that compulsory notification will also drive people away from medical practitioners, who are themselves averse to breaking doctor–patient confidentiality. One physician at a government hospital in New Delhi, for example, has three HIV-positive patients whose wives he has so far not informed; the new law would require him to make the patients' names public.

And no private hospital in India is prepared to handle a patient infected by HIV. A hospital in Bombay that was regularly giving blood transfusion to a thalassemia patient refused to handle her the moment she tested positive for HIV. She got the infection from earlier transfusions in the same hospital.

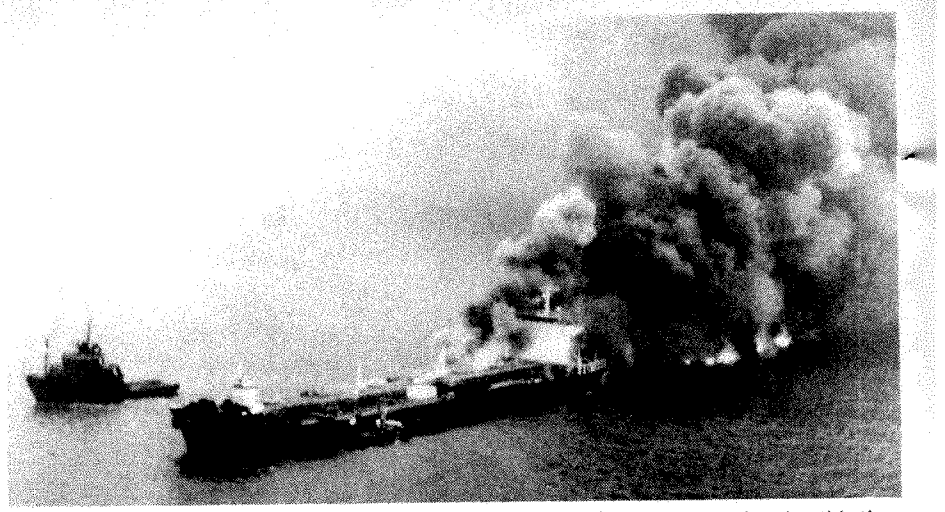
ALASKAN OIL SPILL

Exxon cleans up, clears off

San Francisco

AFTER "one of the most massive mobilizations of manpower and equipment in peacetime history", Exxon last week officially closed oil-spill clean-up operations in Alaska for the winter. But it leaves behind hundreds of miles of contaminated shoreline, and strained relations with government officials and private parties.

Many officials involved in the clean-up charged Exxon with shying away from an obligation to continue fighting the spill, and Alaska's Governor Steve Cowper announced that the state would continue the work that Exxon has now abandoned, and would submit at least part of the expected $21 million bill to Exxon.



The 11 million barrels of crude oil that spilled into Prince William Sound last March, when the Exxon tanker *Valdez* struck a reef, has since drifted southwest into the Gulf of Alaska, tarnishing an estimated 1,100 miles of shoreline. The US Fish and Wildlife Service (USFWS) reported last week that 34,434 birds and 994 sea otters had died as a result of the catastrophe, and officials estimated the toll could reach 10 times these numbers.

Exxon has already spent $1,000 million on the clean-up, including approximately $90 million to settle claims against itself. The company still faces another 140 lawsuits, including one from the state of Alaska, which is seeking unspecified punitive and compensatory damages for a series of alleged violations of state, common and general maritime laws.

Years of comprehensive scientific studies will be needed to assess how marine life and natural resources have been affected. One early result points to a dramatic decline in bald eagle productivity. In the oiled area, 16 eaglets were born for every 100 nests, compared with 49 eaglets in the Copper River Delta just east of the sound. And two-thirds of the occupied nests in the contamination zone failed to produce any young at all, compared to 29 per cent in the non-oiled area.

To counteract public outcry against its decision, Exxon has stressed that it is not going away. A winter crew of 300 people will be retained, and the company has promised to return in the spring to see what, if anything, remains to be done.

Exxon objects to the accusations that it has not pulled its weight. Otto Harrison, general manager of *Valdez* operations for Exxon USA, says his firm has met its objectives to protect fish hatcheries, skim oil off the water, and treat the affected shoreline by mid-September. The company has 'treated' — the formal term for completing basic clean-up on a stretch of shoreline and receiving permission from the US Coast Guard to move on — more than 1,100 miles of shoreline. The treated shoreline is, said Harrison, "environmentally stable", meaning that the beaches are in a condition that will not harm marine or animal life.

Another environmentally sensitive area was threatened by an oil spill at the weekend — this time the Humber estuary and Spurn peninsula on England's north-east coast. Both are 'Sites of Special Scientific Interest', with large bird populations. The *Phillips Oklahoma* (above) and *Fiona* collided and both caught fire. (Press Association.)

But state officials are not satisfied. "The term 'environmentally stable' was created by Exxon, really out of the need to say that they had accomplished something", said Joe Ferguson of the Alaska Department of Environmental Conservation. "It is not a term that we use or agree with."

Removing all the oil is impossible, because some has soaked several feet into the shoreline soil. But state officials charge that so far Exxon has provided mainly cursory treatment — such as blasting oil off the tops of rocks with hot water — and that a much more comprehensive effort will be needed next spring.

USFWS is unhappy with efforts to gauge the spill's effect on fall migration of a variety of bird species, including petrels and shearwaters. The USFWS has asked Exxon to maintain at least six boats in the Kodiak Island area to monitor the migration, but spokesman Bruce Batten said that Exxon has apparently decided "to pull out all of the boats. And so we're left with a job that we're still trying to get done with our own resources, and to some extent volunteers."

A kinder judgement came from the Coast Guard, which co-ordinated the clean-up. Exxon has "done as much as could be done in a short period under very difficult conditions", said Vice-Admiral Clyde Robbins, the highest-ranking federal official in Valdez, and added that the oil posed "no great threat" over the winter.

Robert Buderi

HUMAN GENOME

Sequencing bargain in India?

New Delhi

PRIME Minister Rajiv Gandhi is being urged to launch India's own project to map the human genome, on the grounds that other countries which have already begun the task may not share their results with the rest of the world, and that in any case India might be able to do the job more cheaply.

Genome mapping is not a high priority at the Indian Department of Biotechnology (DBT), whose annual budget is $30 million. But Pushpa Bhargava, director of the Centre for Cellular and Molecular Biology in Hyderbad and a member of DBT's scientific advisory committee, claims that India has "all the capabilities" to do the work, and at a fraction of what the United States plans to spend.

Because most of the money spent on the project would go towards salaries, India could map the entire human genome for less than $200 million spread over 15 years, according to Bhargava. He also argues that India could put itself in a good bargaining position with other countries who want the results. But a more compelling reason, Bhargava suggested to Gandhi, is that India might not benefit from human genome work going on elsewhere.

Bhargava's proposal has few supporters, however, and many disagree with his cost estimate. According to S. Ramachandran, secretary to DBT, the project would require not just manpower, of which India has a plentiful supply, but also equipment, reagents and enzymes, which would have to be imported. And G. Padmanbhan of the Indian Institute of Science, one of six laboratories in the country with the facilities to sequence DNA, "would rather sequence the DNA of a pathogenic organism that causes disease in Indians than that of a human being".

K.S. Jayaraman

BRITISH SCIENCE

Making researchers manage

London

THE management of and financial arrangements for British science are outdated and in need of radical change, a former research council head declared last week. At last week's British Association meeting at Sheffield, Sir Douglas Hague, former chairman of the Economic and Social Research Council, told off researchers for being "arrogant", saying that they should be more accountable for the money they spend on basic research.

Hague, chairman of Metapraxis Ltd, said scientists could manage science provided they acquired an understanding of economics and management, and the ability to work together in "interdisciplinary teams which include and value those who do have such skills". But he complained that scientists would resist change because they had become accustomed to a long period of increasing expenditure on science.

"Scientists are being selfish with society's money", he claimed, declaring that society had the right "to impose on scientists the responsiblity of being accountable for their expenditures and actions".

He described the Advisory Board for the Research Councils (ABRC), of which he was a member for four years, as a "quixotic body" insufficently experienced in making management decisions. The "amateurism with which it too often operated, when concerned with management and organization", worried him: he singled out as an example the "British Empire Syndrome" — whenever a new research programme was started abroad, the ABRC wanted to carry it out in Britain.

One consequence, Hague said, is that Britain has about half as many research centres as the United States, but "given our relative populations and prosperity, one would expect Britain to have one fifth or fewer of the number in the United States". He also described the civil service as "the joker in the pack", claiming that civil servants are at least as "ignorant as scientists" in making managment decisions.

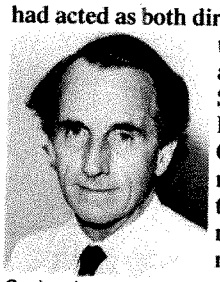
The attack on science management in Britain was sustained by Lord Dainton, the chemist who in his time has been a university vice-chancellor (Nottingham) and chairman of the University Grants Committee. He said it was a "simplistic notion that generous government support for basic and strategic science automatically brings national prosperity".

Because Britain does not have the financial capacity to accommodate the innate tendency of science to expand, he advocated unification of the five research councils to ensure the best deployment of scarce resources, adding that "new opportunities and problems often arise which can only be tackled by multidisciplinary approaches". The percentage of income spent on bureaucracy would also fall.

The proposal that all the research councils should be amalgamated, put forward earlier this year in a report to the ABRC, will probably be decided in the next few months.

Lord Dainton also concluded that government should divest itself of its existing support for industrial research and use the resources to increase support for universities and teaching. The role of government was to facilitate the movement of young people into industry, because market forces alone would not solve the problem. To get to grips with growing competition for limited funds, Hague argued that researchers should measure the cost of undertaking research not in monetary terms but in relation to the research opportunities which must be foregone, terms in which they normally do not think.

Ben Webb



CANCER RESEARCH

CRC and MRC to shuffle the pack

London

THE Institute of Cancer Research (ICR), the largest comprehensive cancer centre in Britain, has created a new post of chief executive in a radical change in management structure. Biochemist Peter Garland will join ICR on 1 November to run a restructured management team.

The new appointment follows the resignation of ICR Director Robin Weiss, who had acted as both director and chief executive while remaining active in research. ICR Secretary Jonathan Kipling said the Committee of Management decided to take the opportunity to review the management structure.

Garland: to run the ICR now reinstitute in line with CRC national strategy.

The ICR now receives £5 million a year from both the Cancer Research Campaign, one of Britain's largest cancer charities, and the Medical Research Council, but MRC is phasing out its contribution over the next eight years and CRC will shoulder the lion's share of the budget.

Garland, who leaves Amersham International after two years as director of research, said he was delighted at the prospect of leading the ICR from the foundations laid by Weiss. Amersham has had to cut back on its research programmes after a fall of profits in the last financial year.

AMERINDIAN HERITAGE

Smithsonian's new formula

Washington

DECLARING that the "anguish" felt by Native Americans was "a weight that one ultimately cannot carry", Robert McCormick Adams, Secretary of the Smithsonian Institution, announced last week an enlarged policy for the return of skeletal remains to Native American tribes where there is a "preponderance of evidence" connecting the bones with modern descendants.

The agreement between the Smithsonian Institution, one of the largest holders of Native American remains, and a variety of American Indian groups comes shortly after a decision by Stanford University to return its archaeological collections to local tribes (*Nature* **340**, 9; 1989), and is an example of an increasing recognition by museum curators that the demands of scientific research do not outweigh the proper and deeply felt religious feelings of modern American Indians.

Discussions aimed at loosening the Smithsonian's earlier policy, under which bones were to be returned only if a direct genealogical link with living descendants could be demonstrated, have been going on for many years. But resolution of the dispute was hastened at least in part by the Smithsonian's desire to pass through Congress legislation creating a National Museum of the American Indian in central Washington. With an amendment incorporating the new agreement, such legislation was approved last week by a House of Representatives subcommittee on libraries and memorials; Smithsonian officials feel confident that the new museum will eventually gain the full approval of the Congress.

But a more important element in reaching the new agreement was, according to a spokesperson for the Smithsonian, the growing conviction of Secretary Adams that the Native Americans' grievance is profound. Adams now has the task of appointing a five-member committee, of whom three will be Native Americans, which will judge demands for the return of remains.

In his announcement of the new policy, Adams estimated that 5–10 per cent of the Smithsonian's collection might ultimately be returned for reburial, but wording of the agreement leaves it entirely up to the committee to decide what is or is not a "preponderance of evidence" in favour of returning bones. Some American Indians want all remains, even those thousands of years old, taken from museums and put back whence they came, but curators at the Smithsonian believe this is a minority view, and that most of the collection will be left intact.

David Lindley

GLOBAL ENVIRONMENT

How green is Japan

Tokyo

AT A conference in Tokyo last week, the heads of the World Bank, the United Nations Environment Programme (UNEP) and the World Meteorological Organization (WMO) lavished praise on Japan for its contributions to the protection of the global environment. But in a series of independent meetings in Tokyo and elsewhere, representatives of non-governmental organizations (NGOs) from all over the world severely criticized Japan for assisting the destruction of the environment in developing nations.

The conference on the Global Environment and Human Response toward Sustainable Development, sponsored by the Japanese government and UNEP, was proposed last year by then Prime Minister Noboru Takeshita. But unlike a similar event organized by UK Prime Minister Margaret Thatcher earlier this year, the Tokyo conference excluded the public as well as NGOs, some of which then organized rival meetings in Tokyo, Kyoto and Osaka.

The government-sponsored conference was the forum for a string of laudatory addresses. Barber B. Conable, president of the World Bank, praised Japan's endorsement of anti-pollution policies, its development of energy-efficient technology and its decision to emphasize environmental activities in its international development assistance programmes as "salutary examples" of how an industrial nation can adapt its policies to meet environmental challenge.

In the same vein, Godwin Oli Patrick Obasi, Secretary-General of the WMO, expressed the world community's "debt of gratitude" to the Japanese government for its agreement, three days earlier, to establish the WMO World Data Centre for Greenhouse Gases in Tokyo. And Mostafa Tolba, Executive Director of UNEP, praised Japan for its "visionary and generous leadership" in providing $2.3 thousand million in Overseas Development Aid (ODA) for protection of the environment in developing countries.

Prime Minister Toshiki Kaifu mentioned Japan's intention to "increase" environmental overseas aid to approximately $2.25 thousand million (¥300,000 million) for the next three years, a commitment made by former Prime Minister Sousuke Uno at the Paris summit in July.

But this figure does not in fact represent an increase in spending. In 1988, environmental ODA commitments on a bilateral basis totalled about ¥110,000 million. And the consequences of Japanese ODA formed one of the main targets of criticism by environmentalists at the NGO conferences.

Martin Kohr from Friends of the Earth in Malaysia, a speaker at an International People's Forum in Tokyo, said that Japanese ODA has been used to finance the building of logging roads in Sarawak where tropical rain forests are being rapidly depleted by Japanese-backed logging activities. And many other participants from South-East Asia complained that Japanese aid is often tied to Japanese commercial interests, and is environmentally destructive.

At the same conference, Bruce Rich of the Washington-based Environmental Defense Fund criticized Japan's representative at the World Bank for failing to speak out on environmental issues. Although the World Bank has in recent years taken a more active concern for the environment, said Rich, Japan's director of the bank has been "noticeable by his silence" on controversial projects named by the World Bank such as the power sector loan for hydroelectric dams in the Amazon in Brazil and the Sardor Sarovar Dam in Western India.

Rich, Kohr and several other environmentalists, including an Amazonian Indian, Paulino Paiakan, chief of the Kayapo Indians, were able to express their criticisms of Japan in a two-hour meeting with members of the Diet.

But several Diet members left halfway through the meeting and those who remained were given only five minutes to respond to the criticisms. Eimatsu Takakuwa, member of the House of Councillors, complained that he has been trying without success to persuade the Diet to introduce a law requiring environmental impact assessment of ODA projects.

Japan, the world's largest importer of tropical timber, seems unlikely to change its policy towards Sarawak. Taizo Watanabe, a spokesman for the Foreign Ministry, was reported in Japanese newspapers last week as saying that Japan has no intention of reducing or limiting imports of tropical wood.

Watanabe cited a UNEP report which says that Japan's imports account for only 2 per cent of the wood cut in Asia. But the figure is misleading: quoting the same report, Japan's Environment Agency says in its 1988 White Paper that, while migrating landless farmers and agricultural cultivation account for most of the tropical rain-forest destruction in Asia as a whole, in insular South-East Asia (Malaysia, Indonesia, Philippines and Papua New Guinea), commercial logging is "the chief culprit of degradation and indirect cause of deforestation".

In Sarawak alone, according to Kohr, commercial logging destroys about 300,000 hectares of primary forest each year while slash-and-burn for agriculture results in a loss of only 9,000 to 16,000 hectares. Nearly all of Sarawak's log exports go to Japan. **David Swinbanks**

WORLD HEALTH

Health for all by year 2000?

Paris

REPRESENTATIVES of the 32 member states of the European region of the World Health Organisation (WHO) met in Paris last week to reconsider how to achieve their common aim of "health for all by the year 2000". Five years into the programme, member states have another ten years to achieve their 38 goals, ranging from adequate housing and clean water to health provision and research.

The European programme follows a 1977 WHO decision to orient its policies towards health rather than illness. The idea of health for all by 2000 "is not just a slogan" says a WHO communique. Sixty-five health indicators have been agreed by member states to allow quantitative monitoring and comparisons within Europe every four years. "This", says Jo Asvall, director of the European region of WHO, "changes the reality of health".

The idea of health for all was agreed in 1978 and the 38-point strategy was adopted in 1984. By the year 2000, WHO wants to see mean life-expectancy at birth increase by ten per cent to 75 years, to reduce infant mortality, and to eliminate measles, poliomyelitis, newborn tetanus, diptheria, congenital syphilis and indigineous malaria.

Other aims are to reduce the frequency of deaths from road accidents, heart disease, cancers and suicides, especially among the young. Some of the goals are closer at hand. By 1990, WHO wants Europe to have "sufficent supplies" of drinking water and, by 1995, to have made "considerable progress" in the campaign against smoking.

But a new report* on the state of health in France suggests that this latter goal may be hard to achieve. Although mean life expectancy in France is now increasing by four months every year, the number of deaths from smoking-related illnesses is increasing and an estimated one in five males smoke more than 20 cigarettes a day.

The increase in life expectancy means that the proportion of the elderly in the population is increasing. In France, there will be an estimated 1.2 million elderly (over 85 years) by 2000. **Peter Coles**

LARGE TELESCOPES

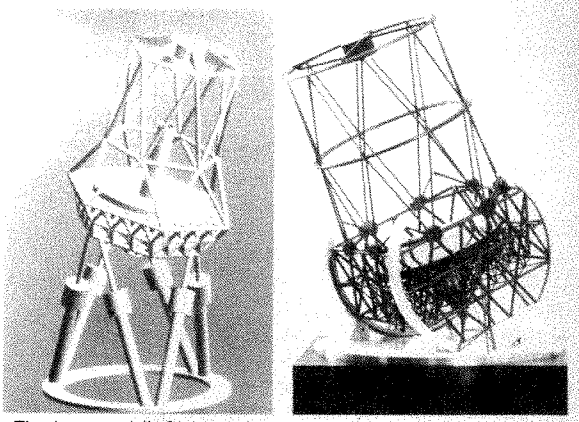
Six feet on the ground

Munich

THE University of Bochum has broken new ground with its entry in the competitions for the funds the federal government has set aside for building a new large telescope. But Bochum's daring has attracted critics as well as admirers.

Bochum is hoping to be the beneficiary of an anticipated DM 200 million ($102 million) the West German government is thinking of spending on a new German Large Telescope (GLT). Theodor Schmidt-Kaler and his colleagues at the university last month revealed a revolutionary "hexapod" design for a large optical telescope. Like all modern telescope designers, Schmidt-Kaler wants to keep both weight and costs down without losing optical quality, but plans to achieve this by building an instrument steered by six legs, all moving independently.

But Klaus Fricke of Göttingen University, leader of a rival group with a conventional design, says "half the world is laughing" at Schmidt-Kaler's proposal, and hopes his group will win the project.



The design for the Bochum hexapod telescope (HPT) was inspired by airline flight simulators, whose position is controlled by piston-like legs. The HPT would have the advantage, according to Schmidt-Kaler, of allowing equally accurate pointing of the telescope across the whole sky. Conventional altitude-azimuth mountings usually have a blind-spot overhead.

The second advantage of the HPT is its relatively low weight. Schmidt-Kaler and his colleagues, Gerhard Schur of Bochum and Karl-Heinz Stenvers of Krupp AG, have had been experimenting with light-weight carbon fibres, and claim that if the HPT mounting is made of these materials the total weight of a 1.2-metre-diameter telescope (the size of a planned prototype) need be only 2 tonnes, as against about 30 tonnes for a conventional design. For the 12-metre telescope that is ultimately planned, this would yield a weight of 120 tonnes, lighter than much smaller conventional telescopes.

The rival project from Fricke's "GLT working group" will be unveiled in the next few weeks. Zeiss AG is collaborating in the project. The proposal is based on a conventional Cassegrain optical system, but uses a new type of segmented mirror. Unlike the US Keck telescope, whose main mirror consists of 36 similar hexagonal elements, the GLT would have a central segment 8 metres in diameter surrounded by smaller mirrors.

Fricke is "extraordinarily sceptical" of the hexapod design. Schmidt-Kaler, he said, is "isolated from the German astronomy community", in part because he "betrayed our interests" by announcing the HPT so early and by not informing the GLT working group of his plans. Fricke said there had been a tacit agreement not to talk about GLT for two years after the West German Research Ministry agreed in November 1987 to pay a large share of the costs for the Very Large Telescope of the European Southern Observatory (ESO).

Schmidt-Kaler rejects Fricke's assertions. He said that he kept the GLT group informed at all times of his intentions and that he is "convinced" that the HPT project will lead to a large telescope. As far as the timing of the announcement, Schmidt-Kaler would only say that Krupp had been responsible for that. The telescope race also matches Krupp against Zeiss, two firms known for producing excellent telescope technology.

The hexapod (left) in computer graphic form, and a model of a conventional mounting for the GLT.

An independent observer, Ray Wilson of ESO, called HPT an "exciting idea" and an "admirable project." But he warned that building a successful HPT will be difficult because the length of the legs must be adjusted over a large range with great accuracy. Nevertheless, "if anyone can make this thing work", said Wilson, "the Bochum–Krupp group can".

Steven Dickman

SCIENCE AND CITIZENS

An unobtrusive neighbour

San Francisco

THE vast medical research, teaching and hospital complex of the University of California at San Francisco (UCSF) has received a clean bill of health from a 20-month environmental study. The study, which cost $1.6 million, is likely to help smooth the rocky relations between the university and citizens' groups whose concern about toxic emissions prompted public disclosure of the medical school's health and safety practices. The campus is in the heart of a residential district near San Francisco's Haight-Ashbury district.

The study may prove a model for universities elsewhere in the United States. UCSF officials say their environmental assessment is the most comprehensive ever undertaken by a medical centre, but, given increased public concern over the environment, other studies are sure to follow. The assessment was carried out by Radian Corporation, an independent company from Sacramento, which examined air, water and soil samples from on or near the campus. It found no detectable effect on air quality and concluded that chemicals in sewer water were a fraction of allowable government levels.

University vice-chancellor Bruce Spaulding says the study shows that medical facilities pose no significant risk to their neighbouring communities — and that the UCSF experience provides a lesson for similar facilities nationwide.

Kathe Traynor, who represents the Haight-Ashbury Improvement Association, says the new study bolsters UCSF's community relations around the present campus. But a planned move of the School of Pharmacy research laboratories to the Laurel Heights area of San Francisco is still at issue. A lawsuit filed by the Laurel Heights Improvement Association of San Francisco Inc. challenged the plan — and late last year the state supreme court ordered UCSF to undertake a new Environmental Impact Report (EIR) in order for the relocation to be approved (see *Nature* **336**, 706; 1988).

Robert Buderi

SITUATION VACANT

Still no taker for NIH directorship

Washington

THE Bush Administration is still casting about for candidates to fill the post of director of the US National Institutes of Health (NIH). The top three candidates on the short list have declined the job.

Anthony Fauci, director of AIDS research at NIH and head of the National Institute of Allergy and Infectious Diseases, removed his name from the list two weeks ago. The drug company Merck has indicated through its press office that its president, P. Roy Vagelos, will not be leaving the company.

William H. Danforth, chancellor of Washington University in St Louis, has also asked not to be considered for the post. James B. Wyngaarden, the previous NIH director, resigned at the end of July.

Carol Ezzell

AIDS TREATMENT

New yardstick for success

Washington

THE use of mortality rates, or of progression to AIDS, as the only objective way of assessing the effectiveness of drugs against the disease may be on its way out. A public conference last week, sponsored by the US Institute of Medicine, concluded that it may be sufficient proof that a drug is working that there should be evidence that it prevents patients' levels of CD4 lymphocytes from falling, at least for the purpose of telling whether a clinical trial should be ended.

Using such a "surrogate endpoint" should allow promising drugs to be identified more quickly than at present. This could be important because early treatment for HIV infection has recently been shown to postpone the development of symptoms.

Counts of CD4 lymphocytes — white blood cells of the type infected by HIV, the virus causing AIDS — have long been used by people with AIDS as a rough indicator of the progress of their disease. But the counts must be made using laser cell-sorting, a technique whose results differ from one laboratory to another, making the data from various medical centres participating in a clinical trial difficult to compare. Measurements taken by centres conducting trials under the aegis of the US National Institute of Allergy and Infectious Diseases are now being standardized.

CD4 counts also vary broadly in an individual according to the time of day. Ratios of CD4 to CD8 lymphocytes are often a more useful indicator than absolute numbers of CD4 cells. But increases in the amount of CD4 cells are usually short-lived even when a given drug is having a positive effect.

Assays for the p24 core protein of HIV and tests using the polymerase chain reaction to estimate the proportion of infected CD4 cells may be useful in monitoring the status of individual patients, but their use as endpoints in clinical trials is distant. Levels of HIV core protein in the blood rise when the virus is actively reproducing, but the protein can be detected only in roughly two-thirds of those infected with HIV. The polymerase chain reaction is used extensively in research, and it can be used to determine if a baby born to an HIV-infected mother has been infected. But it is sensitive to contaminating DNA from sources other than HIV, and results from different laboratories may vary.

The shortcomings of individual tests may be overcome by using several together. But measurements of CD4 cells may be the first surrogate endpoint to be used as a means of obtaining drug approval: a pediatric clinical trial of AZT that ended two months ago may provide the test case.

GENETIC RELEASE

No blanket approval

Washington

THE US National Research Council (NRC), sponsored by the three academies of science, engineering and medicine, this week proposed a new framework for assessing the risks involved in releasing genetically engineered organisms into the environment. Although the report rejects the need for new legislation or a tight system of licensing and regulation, it may counteract the effect of a previous NRC report interpreted by some as giving blanket approval to genetic engineering.

The new report was commissioned by the Biotechnology Science Coordinating Committee, which oversees all five of the federal regulatory agencies with responsibilites for monitoring releases.

Its proposals could bring some uniformity to the present "hodgepodge" system, according to Robert Burris, of the University of Wisconsin at Madison, who was chairman of the steering committee responsible.

The NRC recommends an approach similar to that proposed in February by the Ecological Society of America and welcomed by environmental groups. Even so, Margaret Mellon of the National Wildlife Federation (NWF) is disappointed that the NRC did not provide a means for involving the public in decision-making, but Burris replies that "everything is aimed at trying to make the approach rational so that the public won't have to worry about it".

Instead of attempting to categorize in advance different products according to their potential risk, NRC proposes weighing on a case-by-case basis the characteristics of each organism and its potential effects on the environment, with no reference to the means used to modify the organism genetically. Mellon says that, by not expressly excluding any product from scrutiny, NRC is endorsing a broad net of regulation.

Although NWF is calling for a tight system of registration and licensing similar to that proposed in Britain (see *Nature* **340**, 84; 1989), NRC says that "the complexity and cost of seeking regulatory approval" has discouraged academic researchers in the United States from carrying out field testing of engineered plants. On the contrary, researchers should be encouraged to use genetic engineering, it says.

Three major criteria, "familiarity, control and effects", are proposed for assessing the risk of release of genetically engineered microorganisms. To satisfy the "familiarity" criterion, the microorganism, its intended function and the target environment must be "sufficiently similar to prior introductions that have a safe history of use". Smale-scale field tests can then proceed without the need for any increased oversight.

Releases that do not satisfy this criterion are to be assigned to low-, moderate- or high-risk categories according to people's ability to control the persistence and dissemination of the microorganism as well as its potential for significant adverse effects.

Burris says that existing institutional review committees could adopt the proposed framework. Local oversight should be enough for low-risk field testing — probably 95 per cent or more of all current reseaarch — and federal oversight could be used for "the few cases where perceived risk exists".

Christine McGourty

AUSTRALIAN FAUNA

Koala researcher faces charges

Melbourne

A CONTROVERSIAL Australian koala researcher, widely known for his view that koalas are becoming an endangered species, is now facing criminal charges and a fine of up to $80,000 as a result of his research activities. After an investigation by police and the Queensland National Parks and Wildlife Service (NPWS), Stephen Brown, director of the Koala Research Centre at Queensland's Bond University, has been charged with three counts of transporting and two counts of keeping protected fauna without the appropriate authority.

Brown claims that koalas are endangered because of reduced fertility in females as a result of widespread infection by the bacteria *Chlamydia psittaci*. But his claims have been criticized by other Australian researchers since the first koala biology symposium in 1976. Despite the release of statements at subsequent symposia saying that koalas did not face extinction, Brown has continued to gain public attention, and his research has attracted large corporate and public donations.

Kath Handasyde, of Monash University in Melbourne, says that although researchers have found that some populations of koalas have indeed suffered lower fertility because of chlamydia, surveys have shown that koalas are not endangered. Ronald Strahan, a former researcher at the Australian Museum and convenor of the koala symposia, says that some other researchers, have disagreed with Brown, but that they have been reluctant to voice their criticisms.

The NPWS has now cancelled Brown's fauna permits, preventing him from carrying out his research. His fauna records have been seized and a spokesman for NPWS says further charges may be brought against him.

Tania Ewing

SOVIET SPACE

Wings clipped by economics

London

THE Soviet space programme will have severely practical objectives in the next 15 years. The guiding principles during that period will be those of what is called Programme 2005, and will be concentrated in three main areas: the modernization of commercial satellites, wider use of space facilities for research and more manned flights in Earth orbit, according to the government newspaper *Pravitelstvennyi Vestnik*.

Special emphasis, the newspaper says, will be placed on the satellite monitoring of environmental pollution, satellite broadcasting and satellite emergency rescue systems, as well as map-making and weather forecasting. The manufacture of semiconductors and sophisticated drugs in zero gravity will also have priority status.

During the past 33 years, the paper said, the Soviet Union has spent less than 20,000 million roubles on the development and maintenance of commercial space facilities, while space research has generated some 12,000 million roubles as spin-off. Current annual spending on space is 1,700 million roubles, some "five to ten" times that of the United States, and less than 1 per cent of the All-Union State Budget.

Programme 2005, the report said, will involve the Soviet Ministry of General Machine Building in an outlay of around 6,000 million roubles in 1991–95. This breaks down into 1,000 million roubles for the development and construction of new commercial satellites (excluding their maintenance costs), 2,000 million for research and 3,000 million for manpower costs and new hardware. The newspaper says the programme should produce benefits worth up to 27,000 million roubles — a yield of almost 400 per cent.

The publication of these figures, unprecedented in the history of the Soviet space programme, is not simply an application of *glasnost* to a previously secret area, but is also relevant to recent debate about the cost of the space programme, for many years a subject of dissident black humour now being openly questioned.

A number of the new People's Deputies have used the new parliamentary procedures to express their doubts that space can ever show the cost-effectiveness which is the basis of Mr Mikhail Gorbachev's economic reforms. The correspondence pages of several leading newspapers have carried plaintive and angry letters asking when all the outlay on communications satellites will supply an efficient telephone service.

Soviet journalists, perhaps piqued that a Japanese citizen will be the first pressman to visit the Mir space station, and only partially mollified by the founding of a journalism contest whose winner will get a similar trip, no longer greet every new launch as an unqualified triumph. Last month, indeed, *Izvestiya* published a full-page exposé of the aborted manned Moon programme of the 1960s, the existence of which was not officially acknowledged during the Brezhnev years.

Then — the unkindest cut of all — Dr Boris Egorov, Director of the Soviet Ministry of Health's Centre for Medical Biotechnology, and the first-ever physician in space, recently took advantage of a *Pravda* interview to "protest categorically" against the assertion that new medicines can be produced in space, thus calling into question one of the kingpins of Programme-2005.

But Soviet space planners are fighting back with all the weapons that *glasnost* allows. Major launches, once a secret until after blast-off, are now announced in advance. The commercial value of missions is stressed — the latest manned launch even carried commercial advertising. The Interkosmos joint Comecon programme is now officially commended as a demonstration of Soviet managerial skills and — perhaps in response to the current upsurge of ethnic awareness — the role of non-Russians in the space programme is receiving special mention, from the Ukrainian head of the Baikonur cosmodrome and his Lithuanian on-site political chief down to the 62 ethnic groups represented among the staff at the base.

Vera Rich

POLISH CABINET

Academics in high office

London

POLAND's new minister at the Office of Scientific and Technical Progress is to be Dr Jan Stanislaw Janowski, currently rector of the Academy of Mining and Metallurgy in Krakow. Dr Janowski is a long-standing member of the Democratic Party (SD), one of the two small parties which, for the past 45 years, have voted together with the ruling Polish United Workers' Party. Since 1976, Dr Janowski has represented the SD in the then single-chamber parliament.

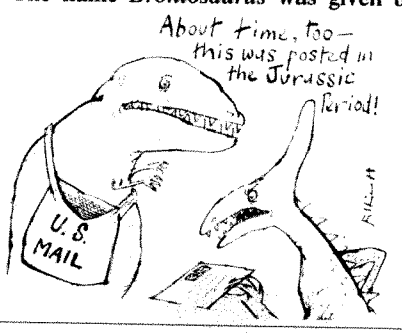
In 1982 he found himself in serious trouble with the SD leadership when he refused to vote the party line supporting the outlawing of Solidarity. He returned to party favour only in 1985, when he became deputy leader of the SD parliamentary group, becoming leader after the "semidemocratic" elections last June.

Last month, when the SD and the equally small Peasant Party (SL) withdrew their support from the Polish United Workers' Party, Janowski was one of the advocates of the coalition which eventually led to the formation of a Solidarity-led government. Janowski will combine ministerial duties with the role of deputy premier.

The education portfolio goes to Dr Henryk Samsonowicz, a historian, who was elected Rector of Warsaw University under the democratic procedures of the first Solidarity period (1980–1981) — and summarily relieved of that office when Martial Law was declared.

Vera Rich

PALAEOPHILATELY



US Post Office flunks fossil test

Washington

THE US Postal Service, financially straitened and recently chided by Consumers' Union for its worsening delivery rate, has now had to admit that its knowledge of dinosaur nomenclature is behind the times. At the urging of Congressman George Brown (Democrat, California) a new set of dinosaur stamps will be issued, on 1 October, with a statement to the effect that what the Postal Service says is a *Brontosaurus* should properly be called an *Apatosaurus*.

The name *Brontosaurus* was given by Charles Marsh to a fossil creature he discovered in Colorado in 1874, and soon became part of every schoolchild's common knowledge. But in 1974 palaeontologists agreed that Marsh's *Brontosaurus* was identical with a previously discovered dinosaur known as *Apatosaurus*, and that the prior name should take precedence.

The Postal Service had used the old name deliberately, on the grounds that it is more familiar to most of the population. But Brown was concerned that a generation of schoolchildren would be dangerously confused without official clarification.

David Lindley

■ **The UK Post Office is being asked — by the Plymouth branch of the British Association — to follow the fashion for dinosaurs on stamps. The occasion is the 150th anniversary, in 1991, of the society's 1841 meeting, when Sir Richard Owen, first director of the Natural History Museum, identified the bones of a large reptile for the first time as *Dinosauria*.** □

Legacy of the Nazis

SIR—The recent discovery in German institutions of anatomical specimens derived from victims of the Nazis has profound implications for medicine and medical science. *Nature* is the only scientific journal so far to report these findings. The relative silence of the scientific press appears to support the concern expressed by the director of one of the institutions involved, the Max Planck Institute of Brain Research, "that the reputation of science might suffer from further publicity".

While Western medicine is seeking to come to grips, in a meaningful way, with medical ethics, it overlooks an issue that challenges the ethical basis of medicine. Ironically, modern medical ethics arose from the experience of Nazi medicine, in particular medical experimentation conducted on unwitting subjects imprisoned in concentration or death camps. The Nuremburg code on medical experimentation was formulated at the War Crimes Tribunal; have medical ethicists forgotten the origins of their discipline?

Now, ironically, while responsible German institutions acknowledge the possession of these specimens and are considering plans for their proper disposal, the medical and scientific community elsewhere remains largely ignorant and silent on the issue. In the long term, that will damage the reputation of science and medicine. Although the medical profession has now effectively dissociated itself from Nazi medicine, which is regarded as an isolated example of evil practised by a few SS physicians, in reality Nazi medicine involved virtually the entire German health-care system in racial selection, enforced sterilization, 'euthanasia' of the mentally ill, research into racial hygiene and genetics and various forms of forbidden medical experimentation. Courses on racial hygiene became part of the undergraduate medical curriculum[2,3]. Yet medicine today continues to ignore the links between medicine in Hitler's Germany and medicine elsewhere.

Scientific medicine developed, for the most part, in the Germany of Koch, Virchow, Roentgen and Erlich. The institutions that acquired and used these specimens are part of the system of medical education that was a model for the modern North American system. Abraham Flexner, the architect of the North American system of medical education, saw the German university system as a model for merging the university and science in the training of physicians[4]. The Nazi physicians responsible for some of the worst evils in recorded history were graduates of this same university system.

That is why this tragic episode of these anatomical specimens must become more widely known. The specimens should not only receive a respectful burial but their existence and burial should be acknowledged and commemorated by all of medicine. There must be public documentation of who those people once were, how they died and how institutions representing science, medicine and higher education used their remains for almost half a century after the defeat of the Nazi regime. A proper documentation and public burial would help to sensitize the profession, and the world, to the fallibility of medicine and the vulnerability of human society.

WILLIAM E. SEIDELMAN

Stanford maligned

SIR—I have just read Alex Comfort's review of *Stalking the academic Communist: Intellectual freedom and the firing of Alex Novikoff* by David Holmes (*Nature* **339**, 347; 1989).

In it, the following sentence appears, in connection with Comfort's claim that academics generally show cowardice in the face of external attack: "If anyone thinks that this was a feature of a unique period, they should have been at Stanford a few years ago when an equally malicious but non-political attack on a distinguished scientific faculty member — also Jewish — found his colleagues, including his Jewish colleagues, looking at their blotting pads in equal silence."

I have been at Stanford for 30 years as a member of the science faculty, and for the past nine as its president. I have no idea what Comfort is talking about. For all I know, there may be a case to be made somewhere. But Comfort doesn't make it; he merely inserts a piece of offhand institutional slander so lacking in documentation that one cannot even identify its source.

DONALD KENNEDY
Stanford University, Stanford, California 94305-2060, USA

Guidelines needed

SIR—Authors of research papers are apparently not the only ones in the scientific enterprise in need of publication guidelines and oversight mechanisms. A journal editor recently held a manuscript of mine for four months before it became clear that he had never sent it out for review and did not wish to do so until I could be persuaded to cite his research. When I refused (because his papers were only marginally relevant), he reluctantly proposed to send the manuscript to two reviewers, with, he said, "my anonymous comments regarding its merits and faults".

The behaviour of this editor is, I believe, contrary to custom and certainly to what the scientific community expects. Such lapses could, to some extent, be prevented or redressed. On the page or pages where a journal now gives its instructions to authors (often demanding a lot in the way of form and format), it should also set out its own guidelines on editorial policy, and say who is responsible for them. It could be stated, for example, that the society's board of directors, or the publishers, had agreed on the listed guidelines. These would include how a manuscript is processed, how many reviewers are used, how long a decision is expected to take, and so on. It is important that a publisher or board should participate in setting guidelines and, when necessary, take part in implementing them. Abuses go unreported in systems where the culprit has been appointed judge, jury and court of appeal.

RICHARD F. SHAW
10201 Grosvenor Place, Apt 522, Bethesda, Maryland 20852, USA

German or Polish?

SIR—Steven Dickman writes (*Nature* **340**, 497; 1989) that the 'Hall of Fame' of the German Museum in Munich "contains busts of 38 'German' scientific greats, from Copernicus (a Pole) to Einstein", thus implying that not all the 'greats' were German, and certainly not Copernicus. One could well argue about the purpose of halls of fame, and Copernicus himself would probably turn in his grave at the thought of Poles and Germans staking claims to his presumed loyalties, but, to be fair to the museum, he was born into an ethnic German family and raised in a German-speaking community. His native town, Thorn (today's Toruń), was first occupied by Poland less than seven years before his birth, and although now an integral part of the Polish nation, its German population was replaced by ethnic Poles only gradually during the past 100 years. By the criteria of his time, Copernicus was a German, as his association with the German 'nation' among his fellow students at Padua University illustrates; by the current definition of nationality, maybe he was a Pole as well. Copernicus, perhaps, is big enough for two halls of fame.

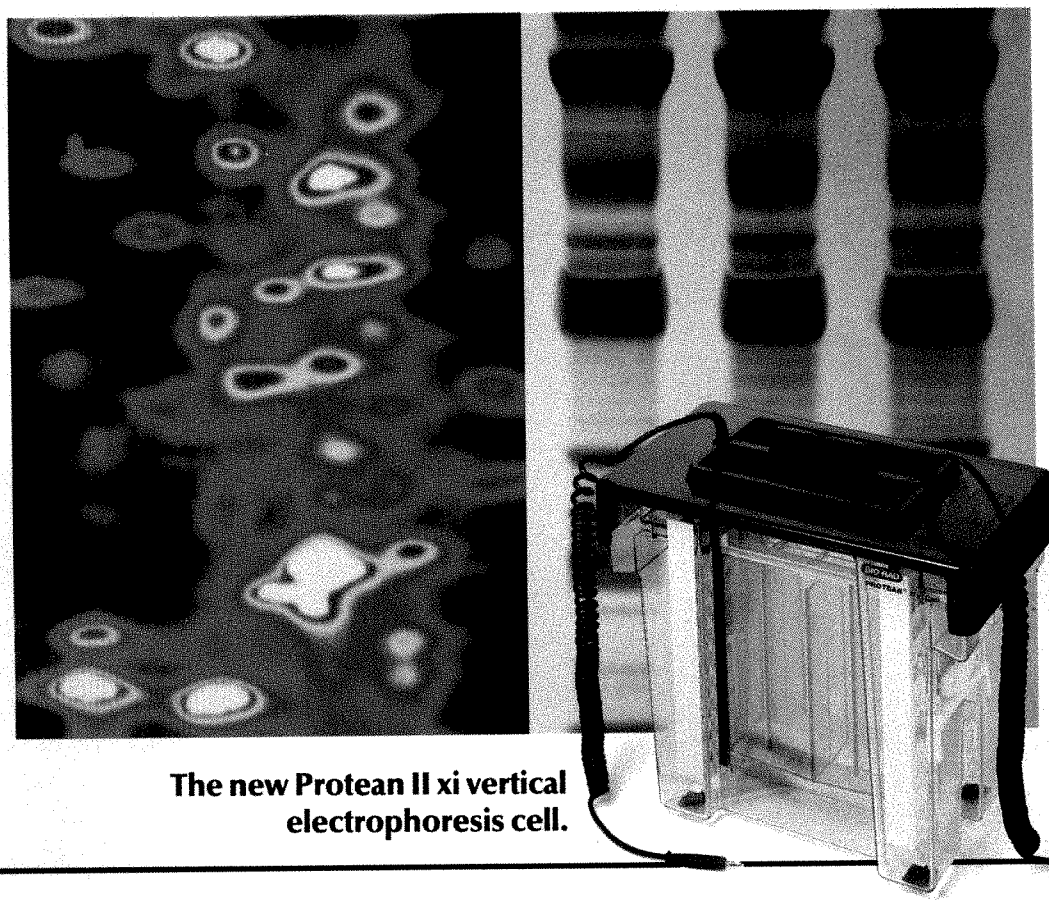
Reader Service No.334

Why did we discontinue the world's most popular vertical electrophoresis cell?

Because we made it better!

Since its introduction in 1984, the original PROTEAN® II cell has enjoyed unparalleled success with more than 10,000 in use. However, good designs are not static, they evolve. Thanks to your input, we have made significant design and performance improvements.



- New state-of-the-art plastic construction for longer life, added strength, and improved chemical resistance.
- New reconfigured cathode for ultra-safe operation
- New alignment cards for greater convenience in assembly
- New softer gasket material for instantaneous leak-free sealing

Plus six other new features to improve ease-of-use, convenience, and versatility!

And, we've kept the features that made the original PROTEAN II cell such an outstanding success, including

- Unprecedented ease of assembly
- Leak-free casting without grease or agarose plugs
- Versatility—runs SDS-PAGE, preparative, gradient, 2D, native and high resolution nucleic acid agarose gels in 16 and 20 cm formats.

Bulletin 1466 tells more. Call or circle the reader service number.

The new Protean II xi vertical electrophoresis cell.

FREE PLATE WASHER? *Well almost. Get our new PROTEAN II xi plate washer system, a $195 value, for only one dollar ($1, 2 DM, 100 yen, 1000 lira, . . .)* with purchase of your PROTEAN II xi cell. Offer good until March 31, 1990.*

**This special offer is available through any Bio-Rad office worldwide.*

Also in Rockville Centre, NY; Hornsby, Australia; Vienna, Austria; Brussels, Belgium; Mississauga, Canada; Watford, England; Paris, France; Munich, Germany; Hong Kong; Milan, Italy; Tokyo, Japan; Utrecht, The Netherlands; and Glattbrugg, Switzerland.

The RadAlert 1201 is a compact radiation monitor with a truly high performance, but a modestly low price – just £169 + VAT (US$299).

Its built in microprocessor gives accurate measurements of both Gamma radiation and X-rays on a clear digital display. RadAlert comes with three operational modes – instant dose rate, extended dose rate (with your accumulated dose since you turned RadAlert on), and counter.

You will find it invaluable wherever you need to monitor anything from normal "background" radiation to 10 millisieverts/h. It will automatically select between micro and milli sieverts, and you can choose integrate periods of 4 seconds or one, two, five or fifteen minutes.

A high performance radiation monitor designed with your pocket in mind.

It's energy compensated over the range 50 KeV to 1.25 MeV.

RadAlert is fully portable (a rechargeable battery is fitted as standard) but it can also be used in a fixed location with our optional AC/DC adaptor.

You can program its audio-visual alarm to trigger at any level across the full range of the instrument. And there's a distinct warning should RadAlert's capacity be exceeded.

For bulk orders, we can customise the software to meet your operational requirements. We could, for instance, re-program the microprocessor to display only the accumulating dose, and feature your company's name. Please contact us for further information.

RadAlert has been fully tested by the National Radiological Protection Board. It comes with three educational booklets and a full 2-year warranty.

Order your RadAlert now by calling us on (44) 1 486 6837, faxing us on (44) 1 487 3023, or returning the coupon. Or contact us on the same phone numbers for more details. Dealer enquiries are welcome.

Thanks for your help!

We asked you, the user of oligonucleotide synthesizers, the producer of oligonucleotides, how we could improve oligonucleotide synthesis for you. The result was Gene Assembler® Plus, our new oligonucleotide synthesizer.

As Easy as A, C, G, T...

- **Truly easy software,** making handling, synthesis and maintainace really simple.
- **Preprogrammed optimised synthesis methods,** including custom synthesis and a program for 5'-aminoalkylation.
- **Unique monitoring system,** reporting the success of synthesis with automatic feedback control to interrupt the synthesis if something should go wrong.
- **Automatic documentation,** of sequences and results.
- **PAC amidites for better results.** PAC amidites give a purer product due to less depurination.
- **Faster results,** deprotection with PAC amidites and support takes only 60 minutes.

The concept of Gene Assembler Plus is to make oligonucleotide synthesis easier, to improve performance and results. Thus making it perfect for all oligonucleotide synthesis including PCR primers.

The positive reaction Gene Assembler Plus has received testifies to the contribution you've made.

Why not contact us today and find out more about what Gene Assembler Plus can do for you!

We help you manage biomolecules.

Reader Service No.295

Sexual behaviour unsurveyed

The British government's refusal to countenance a survey of people's sexual behaviour is demoralizing for those concerned but should not deter them from pushing ahead with the project.

We are all familiar with the idea that people who work on distasteful projects, say the optimum design of dum-dum bullets fired at mammalian torsoes, will cast a pall on the most cheerful company if they talk too openly about their work. But not AIDS researchers, surely? Those I remember most vividly are a group of physicians at the San Francisco City Hospital some years ago; mostly in their early thirties, there could have been no reason, except heroism and the hope that their experience might help the treatment of patients still to fall ill, why they should thanklessly have been running a hospital ward for the indigent and terminally sick. Yet they were a brisk and cheerful lot, and their humour was infectious. No doubt it helps if what you are doing commands most people's approval.

Those in Britain who have been designing the temporarily abortive "National Survey of Sexual Attitudes and Lifestyles" are a different case. Those who have been talking on the telephone are fully aware that little has been done in this field since Kinsey in the early 1950s (and even that, they say, was more like a collection of case-studies with numbers than a survey, given the biassed character of the sample). But one whom I have never met except by telephone put the personal predicament strikingly one day last week: "She's made us feel ... well you know, ... naughty." "She", of course, is the prime minister, Mrs Margaret Thatcher, who declined to let British government agencies spend money on the project. The peculiarly English word "naughty" is to be understood, on this occasion, as "prurient".

All research requires that a person should invest his or her reputation in that of what emerges, but there are some fields of research in which people are especially vulnerable to external insult. It seems doubly cruel that the same people have to suffer self-inflicted insults, otherwise what the Freudians would call guilt, born of nothing more substantial than one person's disapproval.

Luckily, other researchers seem to have been mostly encouraging. But I did meet one sociologist last week who volunteered that he'd have been exceedingly cautious of a proposal to measure sexual attitudes and lifestyles (or behaviour?), given the pitfalls that abound in trusting what people will tell even professional pollsters. But in the trade, it seems to be acknowledged that the questions that most vigorously rouse resentment are about personal incomes, not behaviour. Physicians seem particularly supportive of the project; even on such a scale as that proposed — there would have been 20,000 respondents in the full-scale survey — the data may not pin down the parameters that epidemiologists need to calculate the likely spread of AIDS, but might they not say something about pappiloma virus and cervical cancer?

The potential benefits of a substantial survey along these lines would be even more direct. From the data gathered in the the pilot surveys in 1987 and 1988 (some of which were presented at a meeting of the Society of Social Medicine at Manchester last week), it seems clear that there is a great deal to be learned about the sexual behaviour of adolescents that would quickly inform social programmes now designed in ignorance to cater for them.

That the median age of women at first heterosexual intercourse has fallen from more than 20 to 16 in two decades is, for example, unsurprising, given anecdotal evidence. But it is surprising that, even among the youngest age-group (16–24), nearly a quarter of first intercourses are innocent of contraception. In contrast with the older groups, condoms appear on more than half of these occasions, which might be good news for a government such as the British which has spent a great deal on advertising their utility in the prophylaxis of AIDS on television in the past few years. If the numbers responding had been greater, the chance of disentangling the several possible causes of what seems to have been a dramatic shift of practice would naturally have been much greater.

At this stage, when the numbers are small, it is understandable that there should be relatively little that bears directly on the epidemiology of AIDS. The most telling information would eventually have come from a sensitive knowledge of the rate at which people acquire new sexual partners; multiplied by the chance that an infected person will infect another, this quantity measures the chance that people will become infected. The figures so far show that the average number of heterosexual partners of men in the course of a lifetime is 11.0 and of women 2.9. But the rate of spread of sexually transmitted AIDS depends not on the average but on the behaviour of the most sexually active people, which argues again for the weight of numbers.

The need for larger numbers is further emphasized by the need that a survey intended to throw light on the spread of AIDS should include sufficiently large numbers of those in the high-risk groups, homosexual and bisexual men, for example. Only then can a survey of this kind be related to other kinds of studies, perhaps the tracing of infected people's partners. One of the disconcerting features of the British pilot survey is that the proportion of men reporting homosexual partners is too small to be believable; the succeeding feasibility survey, involving the greater use of self-completed questionnaires, seems to have been more successful.

That appears also to have been true of the response rate, the commonly-used indicator of the representativeness of any survey. In the original pilot survey, the response rate was less than a half, but in last year's feasibility study, it had increased to 62 per cent of those still to be found at their random addresses. But 24 per cent refused point-blank to cooperate, which is too great a proportion for comfort. In passing, it would be interesting to see whether responses to a survey carried out in the next few weeks (there is no time, of course) would have been increased or decreased by the government's refusal to allow this study to be sanctioned, but that is another matter.

Meanwhile, there is a broad question affecting the whole scientific community. The British government is within its rights to say no to whatever it likes, and nobody can justly complain that it has interfered with academics' freedom. On one view, the refusal merely reflects the government's calculation of how many voters dislike the whole idea, and who probably predominate among those who decline to be interviewed. The moral is that the disappointed researchers, but especially their colleagues, should carry the argument for greater awareness to the public.

In the long run, that is how communities such as the British will come to recognise that statistical measures of their behaviour is not an invasion of their privacy, but can be a great social benefit. But there is also a short-term benefit to be won. It is natural that people who have worked for two years on a project suddenly halted should be disconsolate, but the government is not the only possible source of funds. This team deserves a fund-raising drive.

FORENSIC SCIENCE

DNA forensics and the FBI

Rory Howlett

FORENSIC laboratories have been quick to realize the potential of the new DNA technologies such as 'DNA fingerprinting'[1], and these have already been widely used as evidence in both the American and British courts. But there is growing unease that in the rush to exploit the power of the techniques, standards have been overlooked[2]. The Office of Technology Assessment, a research and analytical agency of the US Congress, is presently considering the uses of DNA tests. Its purpose is to gather technical information on the reliability of the various techniques, assess costs and procedural issues, and outline policy implications. Many of the relevant issues were discussed at a recent meeting in Atlanta*.

DNA forensics is a very young science. Up to 1985, forensic scientists were largely dependent on well defined protein polymorphisms, such as ABO blood groups, serum proteins and red-cell enzyme systems, when trying to link a particular suspect with forensic samples such as blood stains. On the basis of such markers, an exclusion of 99 out of 100 individuals would be exceptional; semen markers were even less informative. With the advent of so-called 'DNA fingerprinting', however, forensic science has moved from exclusion to positive identification; for the first time there is at least the potential to identify the donor of a body fluid or tissue to the exclusion of all other individuals except identical twins.

Unique mutations

The identification of individuals on the basis of their DNA depends largely on the exploitation of restriction-fragment length polymorphisms (RFLPs). These result from mutations that create or eliminate restriction-enzyme recognition sites in DNA so that the same region of the genome is cleaved by restriction enzymes to fragments of different lengths in different individuals. An important class of RFLPs is that associated with so-called human 'minisatellite' DNA[1]. Minisatellites are dispersed regions of tandemly repeated sequences detected through a shared core sequence (similar to the generalized recombination signal, χ, of *Escherichia coli*). Many minisatellite loci are highly polymorphic for length alleles because of variations in the number of tandem repeat sequences present between two restriction sites. Such minisatellite 'variable-number tandem repeats' (VNTRs) can be detected using a probe derived from minisatellite sequences from an intron of the human myoglobin gene. This probe, first described by Jeffreys *et al.*[1], detects many highly variable loci simultaneously and generates individual-specific 'DNA fingerprints' of general use in human genetic analysis.

Despite the widespread use of the original minisatellite probe, not everybody agrees that it is the most appropriate for forensic work. This point was clearly made at the Atlanta meeting by B. Budowle, a forensic scientist with the Federal Bureau of Investigation Academy, Quantico, Virginia. The FBI favours the use of probes that recognize variable-number tandem repeats that occur only at single loci[3,4] instead of being dispersed. Such single-locus probes are claimed[3] to be more sensitive than the original Jeffreys probes because they bind at higher stringency. The probes produce simple patterns which, says Budowle, is an advantage when banding patterns from different specimens have to be compared. Furthermore, the single-locus probes favoured by the FBI lack the extreme cross-reactivity of the Jeffreys probe. Thus, whereas the Jeffreys probes detect hypervariability in organisms as disparate as rice and whales, so far as is known the single-locus probes cross-react only with DNA from higher primates[5].

It is widely recognized that several criteria must be met before a genetic marker can be safely used for human identification. First, the background frequency of the marker in human populations must be known. Second, the marker must be stable in forensic specimens and artefacts must be accounted for. Third, the methods and reagents must be readily accessible. Finally, the techniques must have appropriate sensitivity, and standards and required controls must be defined. (The need for care is illustrated in Eric Lander's disturbing account[2] of the case of *United States v. Castro*.) According to Budowle, the FBI has designed protocols to take into account the potential problems associated with forensic use of the new DNA technologies. Training is stringent and FBI research laboratories provide 'blind' samples so that the competence of those actually doing the testing can be monitored.

Several restriction enzymes are suitable for RFLP typing, but the FBI has settled on *Hae*III (ref. 6). This is a very robust enzyme which gives consistent banding patterns even when digest conditions are adverse. Furthermore, it is insensitive to the methylation state of its substrate — an important point because otherwise there would be a danger of artefactual differences due to tissue-specific patterns of DNA methylation.

Forensic samples taken from the scene of a crime are often corrupted by chemical or biological contaminants, or have been exposed to potentially harmful environmental factors such as sunlight. For this reason, the FBI has attempted to validate the use of its single-locus probes by comparing the banding patterns generated from contaminated or environmentally exposed samples with controls[5]. According to Budowle, the data from these studies suggest that the analysis of such samples is valid and reliable and that the chance of a false result (either positive or negative) is negligible, if the tests are competently performed. He believes that such studies will allow courts to assess more readily the weight of the data derived from forensic analyses.

Limitations

Because the quantity and quality of DNA in evidence material can be limiting, it seems that the polymerase chain reaction (PCR)[7], which is capable of greatly amplifying defined DNA sequences, is likely to become an important adjunct to RFLP typing[8]. Indeed, it has already been shown that PCR can be used to make possible the typing of DNA from single hairs[9]. The FBI is also considering exploiting sequence variability in human mitochondrial DNA for forensic work[10]. DNA sequencing is another possibility (G. Sensabaugh, Univ. California, Berkeley), but in this case there will be a need for readily available sequencing technologies with low reading error rates and sequence-variable regions will have to be targeted.

Whatever approaches are deemed most suitable for DNA forensics, it is clear that appropriate statistical methods will have to be developed. Because of the limited resolution of present RFLP technologies, it is often difficult or impossible to distinguish alleles of similar length. To take such limitations of the data into account, Budowle favours the statistical classification of the data into arbitrary fixed 'bins', the boundaries of which are defined by standard markers of known length[3]. The distribution of alleles falling into different bins for any given population can then be used for all subsequent statistical analyses. Such an approach, Budowle argues, is cautious and conservative in that it will tend to overestimate the frequency of rare alleles in the population; it is, of course, the rare alleles that are most subject to genetic drift, founder effects and sampling error. Because it is also these alleles that tend to give rise to the lowest probabilities of a false match, a cautious approach is necessary, says Budowle, particularly given the sparsity of knowledge about the true background frequencies of VNTR alleles in human populations. In any case, Budowle believes that the main emphasis of forensic work should be to exclude individuals who have been falsely associated with a

*Genetics Society of America, 58th annual meeting, Atlanta, Georgia, 30 June–2 July 1989.

forensic sample used as evidence, rather than to identify defendants. For a further discussion of some of the statistical issues raised by the forensic use of genetic fingerprinting, see ref. 11.

It is unfortunate that the use of DNA technologies has been the subject of recent adverse publicity. In the view of Sensabaugh, the evaluation and eventual widespread acceptance of these technologies in the courtroom will depend on the accumulation of a body of experience, and the recognition and acknowledgement of potential problems and pitfalls. An outstanding need is for agreement on when to declare a given test uninformative or sufficiently ambiguous to be unsafe as evidence. In the meantime, it is reassuring to see that agencies such as the FBI are aware of the issues and are taking steps to minimize their problems. □

MATERIALS SCIENCE

Aluminium-based glassy alloys

Robert W. Cahn

A NEW family of glassy alloys based on aluminium, announced by three independent groups[1–5] over the past two years, is eliciting much interest. Being both strong and ductile, the alloys may succeed in technical applications where other metallic glasses have disappointingly failed. Furthermore, as described recently by Dubois and colleagues[2], these glasses do not fit familiar theories and their compositions sometimes resemble those of the remarkable quasicrystals discovered five years ago, prompting important new scientific questions.

Metallic glasses (or glassy alloys) have been studied intensively since their discovery in 1960 by Duwez and his collaborators. The term 'glass' is used in preference to 'amorphous solid' to denote the fact that Duwez made his revolutionary materials by rapid cooling from the melt: the term 'glassy alloy' is preferable to 'metallic glass' because all such glasses have to be alloys as pure metals cannot be made glassy — crystallization occurs even for cooling rates as high as 10^8 °C s^{-1}. Whatever the nomenclature, the examples studied during the past three decades were almost all made of transition metals, alloyed either with other transition metals or with metalloids such as boron, phosphorus and silicon[6]. Apart from a few offbeat curiosities such as calcium–magnesium glasses and transition-metal–beryllium combinations, no other types of glass have been found — until recently.

The driving forces behind the discovery of the new alloys were first, old-fashioned scientific curiosity and second, the need to find glassy alloys whose mechanical strength can be exploited. Unlike the brittle oxide glasses widely used in glass-reinforced plastics, glassy alloys are not only very strong but also often ductile, yet repeated attempts to use them in ribbons to reinforce composite materials have come to nothing, almost certainly because they have been too dense. The only exception is the family of Ti–Zr–Be glasses whose application foundered on the toxicity of beryllium.

Over the past 17 years, small volume fractions of glassy phase have been observed in various binary aluminium alloys on rapid solidification, notably in Al–Cu, Al–Ge and Al–Cr. Inoue *et al.*[7] were the first to turn an aluminium alloy specimen completely to glass: some of their (Fe,Co,Ni)–Al–B glassy alloys had Al contents of over 50 per cent. A little later, Shingu and colleagues examined a series of Al–Fe–Si alloys[8], but these were very brittle and the investigation was dropped. Only one of their alloys, $Al_{69.6}Fe_{13.0}Si_{17.4}$ (which is close to that of the crystalline compound $Al_9Fe_2Si_2$), was completely turned to glass by melt-spinning (the solidification of a jet of molten alloy on contact with a spinning copper wheel). Note that the two auxiliary constituents are familiar from other glasses.

This discovery impressed the French metallurgist, Dubois, working at Nancy, who sought to predict glass-forming ranges in aluminium alloys from structural first principles, an approach he termed the 'chemical twinning model'[9,10]. An essential part of the model is that glass formation is most likely at compositions close to those of stable crystalline compounds — a notion consistent with Gaskell's[11], that the disposition of nearest-neighbour atoms in glassy alloys is similar to that in the unit cell of a crystalline phase. Dubois and colleagues studied[12] the short-range order in the Al–Si–Fe glass discovered by Shingu and colleagues, finding an atomic arrangement very similar to a stable phase of Al_2Cu. Two other groups, Masumoto's at Tohoku University and Shiflet's at the University of Virginia, independently began to investigate aluminium-rich glasses, in particular their composition ranges, mechanical properties and short-range structural order. There was especial interest in achieving the highest possible percentage of aluminium, as this would assure glasses of low density.

Behind Dubois's priority in this 'race', there lies an interesting twist. Dubois and Le Caër enclosed a paper in a *pli cacheté*, a sealed envelope, and deposited it with the French Academy of Sciences on 7 June 1982. It was opened two years later, at the authors' request, and a summary[1] was submitted to and published by the Academy in 1985. It emerged later[2] that the authors had joined forces with the industrial laboratory of Pechiney, the aluminium company, and had been taking out patents since 1982. The first patent discussed a wide range of glass-forming aluminium-rich compositions of up to five components, for example, $Al_{69}Cu_{17}Fe_{10}Mo_1Si_3$. The delay in publication achieved by the popular French device of the *pli cacheté* was probably needed because further patent applications were underway: indeed, an American patent was granted in late 1987.

Dubois's team sought to compare its first glasses, based on Al–Cu–Ni, to the recently discovered quasicrystals, most of which form in Al-rich compositions with transition metals. It turns out that those mixtures of aluminium and transition metals that are most apt to give quasicrystals are also those that require the most silicon to form glassy alloys instead (Fig. 1). The authors have, so far, pursued the matter no further, concluding in their latest paper[2] that "aluminium glasses inspire intellectual modesty and aesthetic contemplation in equal measure". This appealing reaction would also be apposite for recent work by Shiflet and colleagues[13], who find that Al–Fe–Gd alloys which can form glasses, in their equilibrium state have no eutectic (a configuration in which the melting point is most strongly depressed) although this is the usual feature

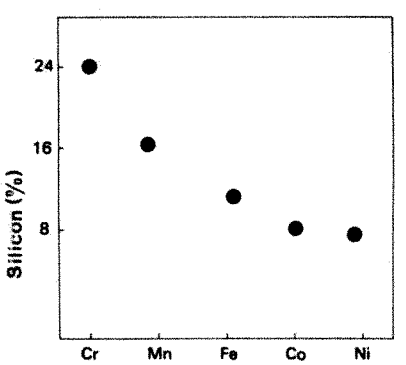

FIG. 1 Minimum concentration of silicon needed to induce glass formation in aluminium alloys. (From ref. 2.)

favouring glass formation.

Observations of rapidly quenched $Al_{86}Mn_{14}$ suggested that the product is quasi-microcrystalline, raising the problem of distinguishing such a structure from true glassiness. This distinction was achieved ingeniously by a novel calorimetric method recently designed for the purpose at Harvard[14]; it would be interesting to apply this technique to characterize some of the new Al-rich glasses.

The relationship between tendencies to form quasicrystals and glasses in aluminium, identified by the French team, is complemented by the Japanese efforts to interpret the role of atomic sizes and the strength of bonds between different atom pairs in influencing the ease of glass formation. (The claim[2] that only the French investigated the fundamentals does not really stand up to examination.) The Tohoku team, renowned for its systematic investigations of metallic glass systems, has discovered the usefulness of rare-earth metals as alloying constituents in aluminium-rich glasses; these additives are so potent that binary and ternary alloys containing up to 90 per cent aluminium form glasses. The binary glasses (Al–Y, Al–La and Ar–Ce) are difficult to make and the acceptable composition ranges are narrow, but ternary compositions (Al–Y–M and Al–La–M, with M=Fe, Co, Ni or Cu) form glasses over wide compositional ranges (Fig. 2).

The tensile strength of these materials can be formidable — often exceeding 800 megapascal (or even 1,000 MPa in the case of Al–Y–Ni[3] and Al–Ni–Zr[15]). Ternary aluminium glasses containing transition and rare-earth metals (especially Ce, Y and Gd) studied by Shiflet and colleagues, have tensile strengths up to 940 MPa. The crucial point is that these strong glasses are also very ductile, so that they are very tough (impact-resistant). Their maximum strengths are twice those available from the best age-hardenable aircraft alloys, and could be exploited in ribbons or wires for reinforcing composites, in surface coatings or in load-bearing structures. Also, the glasses are stable against crystallization up to temperatures ranging as high as 520 °C, a final point favouring their commercial exploitation. □

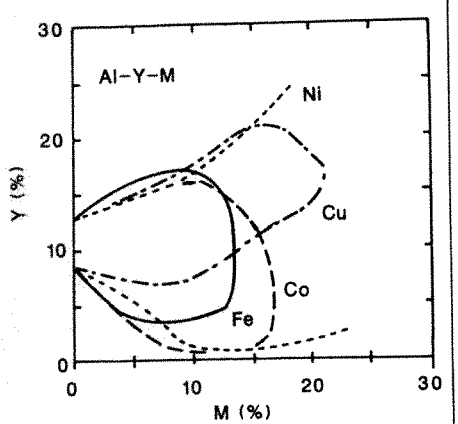

FIG. 2 Binary and ternary aluminium alloys whose composition fall inside the loops are able to form glasses if rapidly quenched. (From ref. 16.)

DNA STRUCTURE

Curves with a function

Andrew Travers

A CRUCIAL step in the enzymatic manipulation of DNA in such important biological processes as transcription, site-specific recombination and the initiation of DNA replication is the local unwinding of DNA within a short region of one to two double-helical turns. This process is frequently preceded by the assembly of a large nucleoprotein complex in which the DNA is tightly wrapped, often as a left-handed superhelix, around a protein core. The constraints on the topology of the DNA within such complexes would be expected to require that both the magnitude and direction of curvature of the path of the double helix are strictly specified. In principle, such a curved path can be imparted to a DNA molecule either by a protein bound to a bendable and flexible DNA sequence, or by the intrinsic bending conferred by particular oligonucleotide sequences — the conformationally rigid oligo (dA)-(dT) tracts[1–3]. Yet, although many examples of protein-induced and intrinsic DNA bending have been reported, it is only now that clear evidence of the functional significance of the curvature as such is emerging. Three new papers[4–6] emphasize the importance of this aspect of the biological function of DNA.

One large condensed nucleoprotein structure that lends itself to experiments designed to address this question is the intasome[7]. This complex mediates the integration of viral (phage λ) DNA into the bacterial chromosome and contains several molecules of two DNA-binding proteins, the phage-encoded integrase (Int) and the *Escherichia coli* integration host factor (IHF). When bound separately to their respective binding sites, IHF, but not Int, induces a substantial DNA bend[8–10], estimated[10] to be at least 140°. One possible function of IHF would be to bend the DNA and thus define the three-dimensional path of the double helix in the intasome; in other words, IHF would act as an architectural element.

This concept has been tested by Landy and his colleagues, who have recently shown[11] that the bivalent Int protein can simultaneously bind to two different segments of *att*P, the genetically defined attachment site on the phage DNA. These segments are separated by a DNA loop whose trajectory is defined by bound IHF. For this trajectory to be strictly defined in the intasome, the bends introduced by the three component IHF molecules must be correctly phased relative to each other: a one-base-pair change in the separation between two binding sites would alter the relative direction of the bends at the two sites by 34° and substantially alter the three-dimensional path of the double helix. On page 255 of this issue[4], Snyder *et al.* show, by varying the spacing between pairs of IHF-binding sites in *att*P that, even in the absence of Int, optimal IHF binding induces bending that would direct *att*P DNA to follow a left-handed superhelical path. This result is consistent with the earlier observation that intasome formation is facilitated by negative supercoiling[12,13] and confirms the importance of

100 years ago

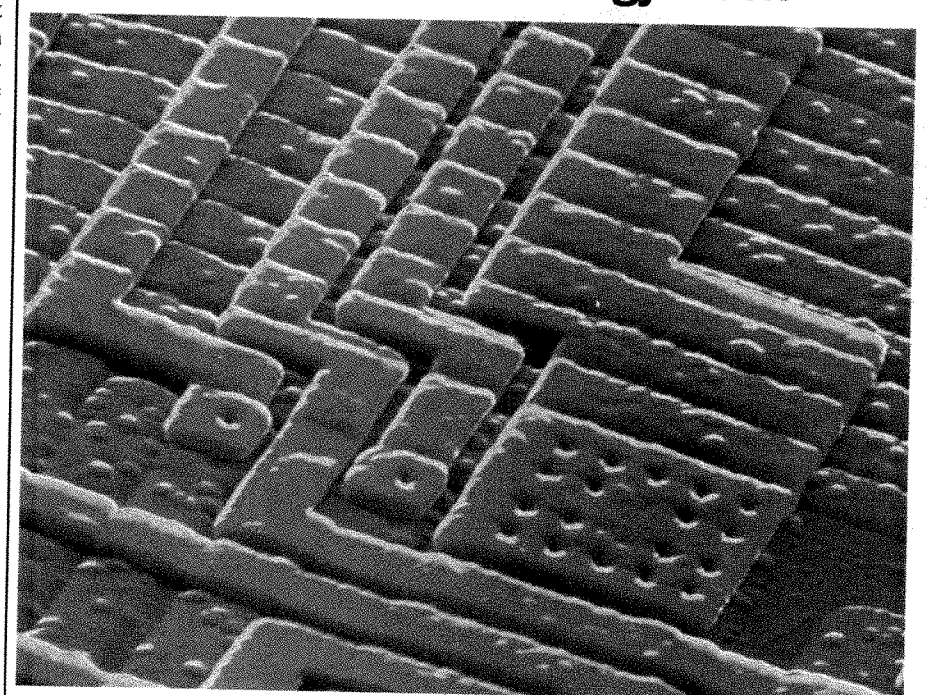
From the British Association

As General Strachey, late President of the Royal Geographical Society, remarks: "The reflection can hardly be avoided that, great as has been the advance of exploration in Africa during the last twenty or thirty years, the interest of geographers will be more and more centred in that continent. Excluding the polar regions, there is no considerable portion of the earth's surface, unless it is in Africa, the essential outlines of which have not been delineated." From *Nature* **40**, 494; 19 September 1889.

IHF as an architectural element.

To test directly whether the DNA bends themselves are crucial for intasome function, Goodman and Nash adopted the strategy of 'bend swapping', as also reported in this issue[5]. When they replaced one IHF-binding site in *att*P by a site with high affinity for CRP (or CAP) — a DNA-binding protein that is unrelated to IHF and which functions normally to mediate cAMP-induced transcription — they found that CRP bends this site to an extent comparable to that of IHF. In such constructs, significant recombination was observed only in the presence of CRP, suggesting that only the bending of DNA and not additional heterologous protein–protein contacts are necessary for the assembly of a functional intasome. This conclusion is confirmed by the finding that an intrinsically bent DNA sequence, with a bend of approximately 120°, can also substitute for the IHF-binding site provided that the bend is appropriately phased. Together these results establish that the principal — and possibly the sole — *in vivo* role of IHF is to bend DNA at specific sites. Such a role would be fully consistent with its multifarious effects on transcription, recombination and DNA replication.

The 'bend swap' experiments establish that, in the intasome, the determinant of biological function of intrinsically bent DNA is its overall curvature, rather than the associated sequence-dependent variations in local DNA conformation. The efficacy of curved DNA in substituting for functions normally mediated by sequence-specific DNA-binding proteins extends to the activation of transcription initiation by *E. coli* RNA polymerase. In the complex formed between the polymerase and the promoter, the DNA is inferred to be wrapped around the protein for up to 60 base pairs upstream of the transcription start point. In many promoters the DNA upstream of a highly conserved hexamer, located 35 base pairs before the start point, is often intrinsically bent. In a recent study of the functional significance of this bending Achtberger and McAllister[6] have shown that promoter activity is exquisitely sensitive to the direction of curvature in this region. Unexpectedly, when correctly phased bent DNA is placed 60–90 base pairs before the start point, beyond the previously observed limit of binding of a single polymerase molecule, transcriptional activity is conserved. This observation suggests either that the curved DNA serves simply to direct the polymerase to the promoter region, or that the curve allows the DNA to bend back to make additional contacts with the enzyme.



In a related set of experiments, Bracco *et al.*[14] demonstrate that the requirement for CRP for the *in vivo* activation of the *E. coli gal* promoter can be overcome by replacing the CRP-binding site by curved DNA. Again, the extent of transcriptional activation is strongly dependent on the orientation of the inserted curve, to the extent that a change of approximately 180° in the direction of bending moves the transcription start point half a double-helical turn upstream — from the *gal* P1 start to the P2 start. This result is fully consistent with the notion that the bending of DNA by CRP is a necessary component of the activation process[15].

The principal conclusion from the studies on both the intasome and RNA polymerase is that the bending of DNA is an important determinant of both the function and the architecture of large nucleoprotein complexes. Interestingly, although it is crucial in both complexes to conserve both the direction and magnitude of bending, the experimental results indicate that the precise length of DNA accommodated by the complexes can vary, albeit in a measured manner. This suggests that the protein components of the complexes are themselves sufficiently flexible to accommodate such variations. A further consequence of this flexibility would be that the topology of the DNA within such complexes would be largely conserved. Thus, each complex would constitute a topological micro-domain delimited by protein contacts towards the flanks of the binding site. An important question remaining is whether the left-handed writhing created by the bending is converted into local limited untwisting and, if so, how. □

A chip off the new technology block

ERA Technology/Marconi.

A pseudo-colour scanning electron micrograph of a 64-K bit memory chip. This voltage-contrast image (55 × 40 μm) shows the paths of applied voltage in yellow. This year marks the 150th anniversary of the founding of the Royal Microscopical Society. To celebrate 'the year of the microscope', the Science Museum, Exhibition Road, London, is mounting the first major interactive display of light and electron microscopy ever staged. Visitors will be able to observe their own specimens and operate a wide variety of microscopical equipment — including scanning (SEM) and transmission (TEM) electron microscopes. Displayed alongside the most advanced equipment available to modern-day microscopists, will be a sequence of instruments and images illustrating the history of microscopy since the Society was formed. The exhibition runs until January 1990. Claire Hooper

COSMOLOGY

Trying to count baryons

Craig J. Hogan

ACCORDING to Eddington, shortly before he died, the number of protons and electrons in the entire Universe is $\frac{1}{2} \times 136 \times 2^{256}$. Although many now would doubt that he was exactly right, the quantity of matter is still a question that provokes strong opinions and prejudices because of its prime significance in models of the Big Bang. How much cosmic matter there is and what forms it takes were the subject of a recent meeting* on *Baryonic Dark Matter*.

Why "*Baryonic*"? This term refers to the baryons — neutrons and protons — that contribute most of the mass of all ordinary matter. The issue is how much of the mass of the Universe is made of such familiar stuff, perhaps in an unfamiliar form, and how much is made of something completely different, for example, an unknown exotic particle left over from the early Universe. The study of baryonic dark matter brings together diverse areas of astronomical research, from comets and asteroids and interstellar matter to intergalactic gas and the physics of the Big Bang. I will focus here only on the narrower question of how much dark baryons can contribute to the mean density of the Universe.

Why "*Dark Matter*"? We now know empirically from the dynamics of galaxies, galaxy clusters and superclusters (from the requirement that matter with known velocities be gravitationally bound to systems of known size) that most of the matter in the Universe is dark — it emits light too weakly to be detected. Nevertheless, fairly firm lower limits on the mean baryon density are available from several different points of view. For example, cold diffuse gas can be seen because it *absorbs* light (W. Sargent, California Inst. Technology); indeed observations of absorption lines in the spectra of quasi-stellar objects (QSOs) give one of the firmest lower limits on the density of dark baryons (although because these are seen at substantial redshifts, the same gas might not be dark today).

Neutral hydrogen

Dozens of QSOs are known at high redshift, and their sightlines traverse a known pathlength through the Universe. About one in five passes through a cloud of matter of very high neutral-hydrogen column density — high enough for the amount of hydrogen to be accurately measured. The physical state of the clouds is somewhat uncertain — they may be gaseous dwarf galaxies or giant gas-rich disks — but their contribution to the mean density is estimated directly from the observations, by dividing the total column density by the total line-of-sight.

Cosmic density is best expressed in special units, using the cosmic density parameter Ω. $\Omega = 1$ corresponds to the density needed to balance exactly the kinetic energy of expansion and gravitational potential energy, giving the Universe zero total energy. (Relating this to a physical density involves knowing the expansion rate in terms of Hubble's constant $H = 50h$ km s^{-1} Mpc^{-1}; h lies between 1 and 2.) A density very close to this critical value is not only predicted by inflation models of the Big Bang but is always expected unless the present epoch is somehow imprinted at the moment of the Big Bang. Yet direct measures of baryonic density, Ω_b, always give very small values; the absorption clouds at a redshift of 2 and present-day luminous stellar populations in galaxies (which may be the same material) each contribute only about $5 \times 10^{-3} h^{-1}$.

A less direct but precise fix on the total baryon density can be obtained by matching the predicted abundances of various elements, which depend on Ω_b, with observations (B. Pagel, Royal Greenwich Obs.). The simplest homogeneous Big Bang model can simultaneously fit the best current estimate of the primordial abundances of several light elements only for a single density, $\Omega_b h^2 = 0.04$, and 95 per cent confidence limits on these abundances still permit only a narrow range of density: $0.04 \leqslant \Omega_b h^2 \leqslant 0.06$. This range has steadily narrowed as observations have improved: the strictest upper limits come from very accurate determinations of helium in gas-rich dwarf galaxies, the lower limits from the lithium in atmospheres of old stars and interstellar measurements of deuterium and helium-3.

If we take this model literally (and its success in fitting diverse abundances suggests that we should) then we can draw several interesting conclusions. First, about 90 per cent of the baryons that exist have not been detected either by absorption or emission and must exist in some currently dark inert form, the most conservative candidate being some form of burned-out stellar remnants (degenerate dwarfs, neutron stars or black holes). This idea can be squared with models of chemical enrichment and evolution of galaxies (a popular theme at the meeting) and models for forming the submillimetre radiation background (S. Hayakawa, Nagoya Univ.). Alternatively, it may be in the form of 'jupiters' or 'brown dwarfs' — bodies too small to burn brightly as main-sequence stars (B. Carr, Queen Mary College; L. Nelson, Canadian Inst. Theoretical Astrophysics). Such bodies would have no appreciable effect on chemical enrichment. Another interesting possibility (D. Lynden-Bell, Inst. Astronomy, Cambridge) uses even smaller degenerate bodies, hydrogen icebergs, but it is harder to see how to form these.

Second, there must also be *some* nonbaryonic dark matter, because the mean density of all dark matter is known to contribute at least $\Omega \approx 0.1$, as measured from the dynamics of various galactic cluster and supercluster systems (this conclusion could not be drawn before these new abundance data were available). Finally, if Ω really is very close to 1 as we would like to think, cosmic matter is almost all ($\geqslant 94$ per cent) nonbaryonic. (Certain theories of galaxy formation also lend support to the idea of a critical density of exotic matter, because the gravitational instabilities needed to break up the primordial Universe can occur in inert dark matter without creating excessive anisotropy in the cosmic background radiation; J. Beckman, Inst. Astrophysics, Tenerife; J. R. Bond, Canadian Inst. Theoretical Astrophysics.) These three conclusions form the orthodox view on the subject.

Modifications

But in spite of its broad success in explaining the pattern of primordial abundances, perhaps one should not believe the standard homogeneous Big Bang model in literal detail. Large-scale lumps of matter, for example, could have collapsed at the period of recombination, when nuclei and electrons first formed atoms, locking up all the 'wrong' abundances in remnants that never mix with observed material. More plausible small-scale departures from homogeneity, such as might be expected from a cosmic phase transition from quark to hadronic matter, occurring at a temperature several thousand times that for nucleosynthesis, would create neutron-rich pockets of matter at nucleosynthesis. The effect leads to a modification of the abundance predictions that reproduces the observed abundance pattern over a wider range of baryon density than in the standard model — perhaps even up to the critical density. The attraction of this idea is that no exotic matter would be required.

When strong-interaction physics is better understood, such modifications to the simplest Big Bang might actually become mandatory; present theories are mixtures of calculation and conjecture. Modelling of these universes is, however, gradually moving closer to realism (W. Fowler, California Inst. Technology; K. Sato, Tokyo Univ.). Supercomputers are being used to compute particle diffusion and nuclear reactions both realistically and simultaneously; new laboratory experiments must be performed to measure

* NATO Advanced Study Institute *Baryonic Dark Matter*, Cambridge, UK, 17–28 July 1989.

ordinarily unimportant reaction rates that dominate in a neutron-rich environment. New species are emerging that may be cosmologically prominent: primordial beryllium and even heavier elements are now being predicted to occur in observably copious quantities. Current indications are that such models may achieve $\Omega = 1$ only over very narrow ranges of parameters, but much theoretical refinement remains to be done.

The excitement now is that nuclear abundances might eventually be used to probe not just the mean density of baryons, but also events at a much earlier time — not just the first three minutes, but even the first three microseconds, when the Universe turned from quark soup into ordinary hadronic plasma. □

ARCHAEOLOGY

New Bronze Age civilization

Paul Bahn

A BOOK published privately by the Ligabue Study and Research Centre[1], has brought to light the recent discovery of a distinctive civilization of the Bronze Age (late 3rd to early 2nd millennium BC), contemporary with those of Mesopotamia, Egypt and the Indus. Until the discovery, in the semi-desert steppe region of northern Afghanistan known as Bactria, it had been thought that the eastern area of Central Asia was uninhabited through the Bronze Age, entering the historical record only as a part of the Persian Empire in the 5th century BC.

In the mid-1970s, however, a great abundance of objects appeared on the antiques market in the Middle East and Europe that came from clandestine excavations in northern Afghanistan. These represented the first definite evidence of a civilization which, at that stage, could not be pinpointed in space or time. All that was known was that the items — bronze, gold and silver, and stones such as calcite and chlorite, and semi-precious stones like lapis-lazuli, turquoise and carnelian — had been plundered by villagers from burial sites in southern Bactria; and that many were comparable to, albeit very distinctive from, objects of the great civilizations of the 3rd and 2nd millennia BC in Egypt, Mesopotamia and the Indus. Certain items were acquired by important museums such as the Louvre[2] and New York's Metropolitan Museum of Art[3], but many went to private collections.

This richness in metals and fine statuary revealed that Bronze Age Bactria had hitherto unsuspected wealth, as well as technological and artistic achievements. It aroused the interest of Soviet scholars, and led to a Soviet–Afghan expedition that explored the southern Bactrian Plain from 1969 to 1979, under the leadership of Viktor Sarianidi, director of the Moscow Institute of Archaeology. Their surveys and excavations led to the discovery of numerous important sites[4,5].

Sarianidi saw many tombs from which the rich grave goods had already been plundered; they appeared to be catacomb pits with niches at their base that originally contained the objects. The placing of portable wealth in tombs is characteristic of the Central Asian Bronze Age, whereas in Mesopotamia and other contemporary civilizations, tombs that are not royal contain few such items.

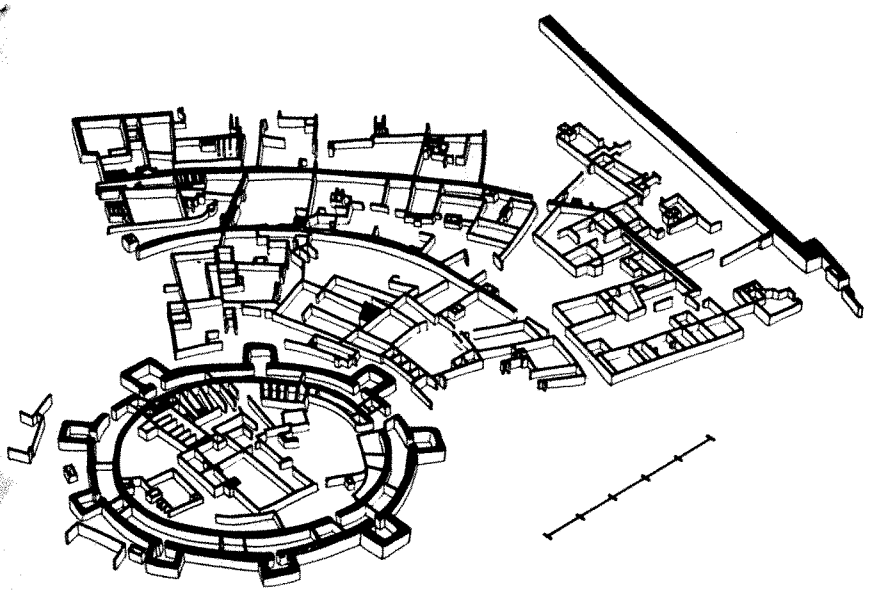

FIG. 1 Axonometric view of the 'Temple' at Dashly 3 (after Sarianidi). (Scale bar 25 m.)

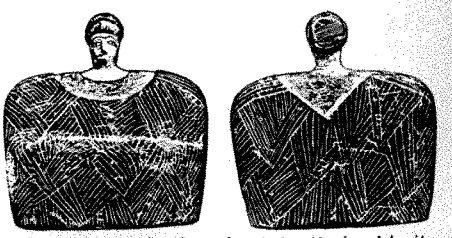

FIG. 2 Composite female statuette in chlorite and white limestone, about 10 cm high.

Perhaps the most important discovery to have been made so far is the architectural complex of the Dashly Oasis in northern Afghanistan. Two major structures, dubbed the 'palace' and the 'temple', have been uncovered at the site of Dashly 3. The former comprises a large rectangular walled area, 84 × 88 m, which encloses a central court measuring 38 × 40 m. It was clearly built as a planned complex, using bricks of standardized size, and its geometric layout, so different to the architectural use of space in the Indus, Iran and Mesopotamia, is echoed in the designs of the metal compartmented seals that seem to characterize the Bactrian Bronze Age. The 'temple', on the other hand, is a circular structure some 40 metres in diameter with nine towers around its perimeter (Fig. 1), and may have been defensive: certainly the Bactrian Bronze Age is distinguished by the large number of fortress sites located within towns containing elaborate structures.

An alternative interpretation is that Dashly's 'palace' is in fact a market place or bazaar, and its 'temple' a caravanserai[6]. That would certainly fit with the likelihood that the Bactrians were first and foremost nomads; their seals bear depictions of tethered and harnessed camels, as well as cattle, sheep and goats. Their region was a kind of emporium for international trade, serving as a vector and link between different cultures and laying the bases for the great caravan routes that would join Asia and Europe for thousands of years. It held the monopoly on commercial traffic along these routes, and those controlling the flow were able to amass concentrations of the precious and prestige goods that were to lead to their civilization being discovered by archaeologists.

As not much work has yet been done, we still know very little of the social organization in Bronze Age Bactria, or of its political or economic system. This was not, however, Mesopotamia in Central Asia; Bactria did not develop into an integrated state, and it never produced writing. It remained a cross-roads of trade routes, not a stable form of civilization.

The new book[1] has brought together a series of essays by leading specialists as well as a superb photographic archive of Bronze Age Bactrian objects, many of

them in private collections and derived from the chaotic and uncontrolled period of clandestine excavation. They include seals, vessels of stone and metal, pottery, and an astonishing variety of metalwork, most of it apparently non-utilitarian, including animal figurines, spectacular axes decorated with animals, and large pins with animal or geometric heads. Perhaps the most striking objects are the composite statuettes in chlorite and white limestone (Fig. 2).

Distinctive as it is, this material nevertheless shows plainly the influence of surrounding cultures, underlining the interrelated system that covered the whole of the Middle East at the time, linking the world of the Indus with the Iranian Plateau and the Sumerian city states. It is to be hoped that archaeological activity will soon be able to recommence in Afghanistan, so that Soviet and other scholars can learn more about the Bactrian civilization. □

ECOLOGY

Upwardly mobile roots

Peter D. Moore

STRANGLER figs of tropical forests have a certain macabre fascination, perhaps because their lifestyle is more overtly aggressive than that of most plants. They begin life in the canopies of host trees, germinating in pockets of humus formed by epiphytes and litter on branches, in leaf bases and in junctions with the trunk. Unlike other epiphytes, the maturing figs establish contact with the ground by the development of long twining roots; their subsequent growth may totally eclipse that of the host and result in its death. Starting life as an epiphyte has the advantage that light levels are higher than at the forest floor, and the depredations of animals and fungi may also be avoided. They also benefit from the higher nutrient levels found in the canopy humus pockets, according to recent work on the strangler figs *Ficus pertusa* and *F. trigonata* in Venezuela by Putz and Holbrook[1]. The figs may even produce upwardly growing roots from the ground so that they can continue to tap this elevated nutrient resource after contact with the soil is established.

One might suppose that nutrients such as nitrogen, phosphorus, potassium and magnesium would be in short supply for an epiphytic plant. Suspended above the influence of the soil supply, such a plant is essentially dependent on nutrient input from precipitation, together with some recycling from the decomposition of trapped leaf litter and perhaps some fixation of nitrogen by cyanobacteria, either free-living or as lichen symbionts. But there is also a nutrient supply from the leaching of the canopy leaves. In the case of temperate woodlands, it has long been recognized that a very significant proportion of the canopy to soil nutrient movement takes place via such leaching processes[2], and studies of the Spanish moss (*Tillandsia usneoides* — a bromeliad epiphyte of the south-eastern United States) have demonstrated[3] a close dependence of the epiphyte on this supply of nutrients. Trees with easily leached canopies (such as pondcypress, *Taxodium distichum*) are richer in Spanish moss than those with low canopy leaching (such as slash pine, *Pinus elliottii*). So nutrient supply of this type may limit the establishment and growth of epiphytes.

P. D. Slocum/Oxford Scientific Films

Deadly embrace of the Florida strangler fig, *Ficus aurea*.

The nutrient resource that lies in the epiphytic ecosystems of the canopy may be tapped by the very trees that support them. Nadkarni reported[4] that many host trees in both temperate and tropical rain forests exploit the organic debris of their epiphyte communities by producing adventitious roots from their branches below the epiphyte mat. This may be a particularly important source of nutrients if the forest soil is poor, as in the case of the temperate rain forests of Washington State on the oceanic western coast of North America, where vine maple (*Acer circinatum*) and red alder (*Alnus rubra*) have particularly heavy epiphyte loads and well-developed canopy roots.

But tapping the canopy nutrient reservoir may go one step further. Sanford has described[5] tropical forest trees in the Amazon basin with apogeotropic roots. These emerge from the soil, grow up the trunks of neighbouring trees and tap into the nutrients leaching from their canopies. To test the role of nutrients in the development of these roots, Sanford built artificial columns topped with 'baits' consisting of forest litter or manure, and some empty controls. The most extensive development of apogeotropic roots was found on the manure-topped structures and the least on the controls, showing that the roots do indeed grow upwards in response to nutrient supply.

The work of Putz and Holbrook[1] on Venezuelan strangler figs growing on a host palm, *Copernicia tectorum*, shows that they too produce apogeotropic roots, so ensuring that they remain in contact with the organic pockets in the canopy even when they have an independent, ground-based root system. The suspended 'soil' in these pockets was found to be richer in nitrogen (× 3), potassium (× 6) and magnesium (× 1.5) than the soil beneath the trees, so the rewards of climbing back up the tree are apparent. A further interesting observation is the absence of vesicular arbuscular mycorrhizal infection in the epiphytic roots. It is unknown whether this is because such infection would be of little benefit to the plant or because physical difficulties prevent fungal infection.

The strategy of beginning life as an epiphyte therefore seems to have clear nutritional advantages which may persist in later life by the development of upwardly mobile roots. But this will prove of value only if the host tree survives beneath its fig load. The quality of mercy, we are told, droppeth as the gentle rain from heaven, in which case the strangler fig might well benefit from exercising a little of the same and thus be assured of a continued supply of nutrients from the canopy of its reprieved host. □

PLANT VIRUSES

Spreading the word

David Baulcombe and Roger Hull

A SUBJECT that is attracting increasing attention among both plant virologists and cell biologists is the movement of viruses through plants. Progress in that area was evident at several recent meetings*, which have covered various aspects of the molecular biology of plant viruses. But the same meetings have demonstrated that molecular biology has confused further some of the thornier problems of plant virus taxonomy.

Viruses move through plants either by short-distance cell-to-cell spread through plasmodesmata or by long-distance spread through the vascular system. There is increasing evidence that cell-to-cell spread is facilitated by one or more virus gene products, the most studied of which is the P30 protein of tobacco mosaic virus. Using various manipulations of an infectious cDNA clone of the virus, W.O. Dawson and K. Lehto (University of California, Riverside) showed that the nearer a gene was to the 3′-end of the genome the more strongly it was expressed but that, within the limits examined, it was not the strength but the time of expression of P30 that was important for efficient virus spread; early expression was crucial for proper function. How P30 functions is still unknown but there are various pointers. The *in vivo* expressed product is phosphorylated (D. Zimmern and A. Haley, MRC Laboratory of Molecular Biology, Cambridge). Nicotinic acid blocks the transport of tobacco mosaic virus in leaf disks and this inhibition is overcome by cyclic AMP or by papaverin or calerotoxin, both of which increase cyclic AMP levels in leaves (J.G. Atabekov, Moscow State University).

Movement models

Broadly speaking, there are two models to explain how viruses move from cell to cell. In one, there is a specific interaction between the virus and the movement apparatus that allows the virus to translocate. In the alternative model, the intercellular connection is 'gated' so that abnormally large molecules, including virions or viral nucleoproteins, can pass through. So far, several lines of evidence point towards the second model, although there will be some complications. The absence of specificity in the process is suggested by the observations that some viruses assist movement of other viruses in certain hosts (Atabekov). In one example, this interaction is manifested as complementation of a defective homologue of P30 in tobacco rattle virus by intact tobacco mosaic virus (V. Ziegler-Graff, Sainsbury Laboratory, Norwich).

Other experimental evidence for the gating model is provided by transgenic tobacco plants that express the P30 gene. In these plants the P30 protein is associated with plasmodesmata, especially in older leaves (D. Atkins, John Innes Institute, Norwich). The gating capacity of plasmodesmata in the plants was measured by video-intensified microscopy of fluorescent dyes of different sizes that had been encapsulated in liposomes and injected into the vacuole; the liposomes fused with the tonoplast membrane and released the dyes into the cytoplasm (W. Lucas, University of California, Davis). Control (non-transformed) plants did not allow cell-to-cell movement of dyes of relative molecular mass (M_r) greater than 800, whereas in the transgenic plants the gating of 11,000–17,000 M_r dyes was observed. Of course, viruses are much larger, so simple gating cannot be the whole story.

Although there is much less information about long-distance transport of viruses there is one important experiment that throws light on the involvement of the viral coat protein. T. Meshi and Y. Okada (University of Tokyo) mutated a cDNA clone of tobacco mosaic virus so as to disrupt the origin of virus assembly but to retain the coat protein sequence. This mutant, which expressed coat protein but was defective in particle assembly, spread systemically through the plant almost as rapidly as the wild-type virus. Thus, efficient assembly is not necessary for long-distance movement, though other experiments show that expression of coat protein is required.

A role of coat protein in transport of virus within the plant is also suggested from data obtained with plants transformed to express the viral coat protein. These plants are resistant to viral infection due to an action of the coat protein at several points in the infection cycle. An effect on transport is inferred from experiments in which efficient movement of virus through the stem is prevented by grafting a section of a plant expressing coat protein into the movement path of the virus (R. Beachy, Washington University, St Louis). Curiously, it was necessary to include a leaf on the grafted segment, otherwise the virus moved normally.

There is also an effect of coat-protein expression on virus disassembly, demonstrated in protoplasts of coat-protein-expressing tobacco transfected with pseudovirions — non-viral RNA, in this case glucuronidase mRNA, coupled to viral origin-of-assembly and packaged *in vitro* (T.M.V. Wilson, John Innes Institute, Norwich). Expression of pseudovirions was inhibited in mesophyll protoplasts but not in epidermal cells. As the epidermis is where infection is established, at least for mechanically-inoculated tobacco mosaic virus, it may be necessary to invoke another level of coat-protein action in order to reconcile the mesophyll specificity with the observation that coat-protein expression on a local lesion reduces the efficiency with which viral infection is established (Beachy). Thus, the analysis of coat-protein-mediated resistance is leading to discovery of new processes in the viral infection cycle. In addition, the complex mechanism underlying the resistance suggests that this will be an effective and durable trait for use in agriculture. The acid test will be in the field under a variety of conditions, and subject to environmental acceptability.

Taxonomy

Viral taxonomy has always been a difficult area and is likely to remain so following new discoveries about the organization of RNA viral genomes. Many of the previous groupings have now been blurred by the discovery that relationships between viruses vary in different parts of the genome. For example, the three different luteoviruses sequenced are all interrelated at their 3′-ends but at their 5′-ends the relationships differ. As summarized by R. Goldbach (Agricultural University, Wageningen), the 5′-end of beet western yellows luteovirus is similar to southern bean sobemeovirus; barley yellow dwarf luteovirus is similar to tobacco necrosis virus and carnation mottle virus; potato leafroll luteovirus has no obvious similarity to any of these viruses.

Another example of RNA recombination that may throw light on the mechanism of hybrid genome formation is the template switching observed in satellite RNAs of turnip crinkle tombusvirus. These RNA satellite molecules comprise, in part, a true satellite RNA that is not obviously similar to the helper virus and, in other parts, remnants of the helper virus genome. It appears that the replicase, having completed synthesis on one strand, or dropped off that strand, has a propensity to re-initiate synthesis at internal sites with similarity to the terminal promoters (A. Simon, University of Massachusetts). Transcription continues contiguously with the pre-existing RNA strand, producing a mosaic of genomic RNA sequences.

Clearly, good progress has been made with the analysis of the viral side of the pathogenic interaction; one looks forward to equally good progress with the analysis of the diseased and resistant plant. □

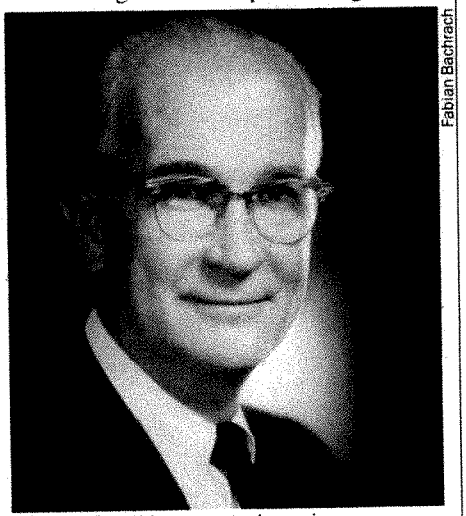
William Shockley (1910–1989)

WILLIAM SHOCKLEY, who died on 11 August in California, must have been one of the most controversial scientists of this century. He collaborated with John Bardeen and Walter Brittain in the invention of the transistor, which has revolutionized modern life. As a driving force behind the exploitation of miniaturized electronics, he was sometimes called the father of silicon valley. But in the last decades of his life, these achievements became overshadowed by the notoriety of his views on racial differences.

It seems that, having gained the Nobel Prize for physics for his work on transistors, Shockley developed an affliction, shared by a few other laureates, that is rooted in public reverence for the prize. The victims (so far, always male) note that their opinions on almost any subject are treated with respect, even in fields in which they have no expertise; and deciding that one of these fields is dominated by stick-in-the-muds, they propose to bring them a breath of fresh air.



Shockley selected social anthropology and genetics. Human intelligence, he proposed, is inherited, and blacks are genetically inferior in intellect to whites: "genetics plays a role in the disadvantages of our nation's black minority. My research on IQ and race gives the estimate that, in negro populations with average IQs in the 70 to 90 range, each additional 1 per cent of caucasian ancestry raises average IQ by 1 per cent"[1]. The latter point he made in spite of the wide margin of error in IQ measurements. Shockley proposed a "voluntary sterilization bonus plan . . . based on payments of a thousand dollars for each point below 100 IQ".

McClelland's view[2], that IQ measurements are "part of an elitist mechanism to discriminate against the disadvantaged" typifies the low value specialists place on IQ measurements. The allegation that any ethnic group has an hereditary lack of intelligence is contrary to measurements of human genetic variation. For example, the estimated number of gene differences between individuals from different populations (caucasian, negro, Japanese) is only slightly greater than the number between individuals from the same population[3]. Furthermore, the allegation goes against people's aspirations towards unity. As a result, Shockley's lectures caused near-riots at campuses.

Shockley admitted in 1965 "several intellectuals have discouraged me from publicly expressing" the ideas, but added "I have faith in the long-term values of open discussion"[4]. Although his ideas, which were not novel, were examined and rejected, he continued to advance them.

More palatable than his ethnic proposals were Shockley's views on the inheritance of genius. The emergence of genius that transcends circumstances is well known. Examples include the mathematician Ramanujan and, in music, Mozart.

Shockley evidently favoured the idea that the genes that produce geniuses

Fabian Bachrach

William Shockley — notorious views.

should be passed on to offspring through insemination, making, at the age of 68, a personal contribution to this effort via a sperm bank in Southern California. This donation he discussed at length in an interview with *Playboy* magazine[5]. Younger donors are usually preferred because of the lower count of viable spermatozoa in older men, not to mention unsubstantiated speculation that deleterious mutations may accumulate in the germ line. (There is also the problem of genetic recombination, famously noted once by George Bernard Shaw. It is claimed that the beautiful actress Ellen Terry expressed a wish to mother a child by him that would have her looks and his brains. Shaw's diffident reply was that he feared the child might have his looks and her brains.)

Shockley argued that "the breeding of good genetic material, whether the people are rich or poor, is desirable. We want more Lincolns, not fewer", and bolstered this simplistic approach by quoting Herman Muller whose advocacy of eugenics is generally rejected, in spite of his eminence in genetics.

It is regrettable that Shockley's great contribution to the 'transistor age' is marred by his ideas on genetics. Astonishingly, he viewed[5] his theories of 'dysgenics' as more important than his work on the transistor, and continued to publicize these ideas at the same time as another Nobel laureate, Martin Luther King, led us in the opposite direction. DAEDALUS

Dental telepathy

OUR sense of touch is almost totally ignored by modern information technology, except in the special case of Braille for fingertip reading. Daedalus sees this as a lost opportunity. He points out that touch is most discriminating, not at the fingertips at all, but at the tongue. We all know how instantly the tongue detects and explores the smallest dental changes: persistently reminding us, for example, of a tiny chip lost from a tooth. Dental patients often complain of irregularities in a new filling that the dentist can hardly even see.

So Daedalus is devising a new communication device, the DREADCO Datadenture. His prototype has a datahead, resembling the printing head of a dot-matrix printer, mounted in the centre of its dental plate. A matrix of tiny pins, each capable of independent vertical travel, can present the tongue with a wide range of possible conformations. Toothless volunteers and DREADCO dentists are cooperating to discover how many configurations of the active surface can be distinguished and how rapidly, what codings are most easily learnt, and so on.

The prototype gets its power and information from a rather clumsy cable entering the mouth. The final design, more elegantly, will use magnetic induction. The primary of the drive-transformer will be mounted on the wearer's collar, and will energize the pin-actuating coils in the wearer's mouth as secondaries. Each drive-coil will be given a different resonant frequency, so that the induction link can address them all individually by simple frequency modulation. All the coding circuits and power-supply units would be safely outside the body, so that the mouth-borne data head may even be miniaturized to the size of a single tooth filling. In exchange for this much more modest dental sacrifice, the wearer would gain a wonderful private data-link, fed from information relayed to the collar induction unit by a nearby transmitter.

At first Daedalus saw his dental data-link as an exotic private paging device, perhaps calling the ambassador unobtrusively from the embassy party to cope with sudden international crises. Less romantically, he now sees it as a source of steadily updated 'background information' for working professionals: giving the time or the stock-market prices, the changing output of a plant or the speed and heading of an aircraft. The user would soon learn to 'read' it quite automatically, while coping with foreground tasks, scanning instruments or talking to colleagues. Thi parallel data-path would be wonderfully clear and distinct; even in confusion or dark or deafening noise, the private 'voice in the mouth' would continue to speak.

David Jones

Honeybees and 'yellow rain'

SIR—The misidentification as a biological warfare agent of the 'yellow rain' produced by defaecation during massed flights of the giant honeybee, *Apis dorsata*, in South-East Asia[1], has focused attention on the phenomenon of mass defaecation. We now suggest it can be explained by the need to prevent the temperature of bees' nests becoming so hot as to endanger the larvae.

When honeybees remain close together in the hot and humid tropics, their corporately generated heat must be dissipated. European honeybees (*A. mellifera*) evaporate water to keep the hive's temperature below about 37 °C, the thermal limit for larval life[2,3]. Individuals of *A. mellifera* flying in extreme heat regurgitate nectar, let it evaporate on their mouthparts, and re-ingest the cooled droplet[4] (a cycle we call gobbetting). *Apis dorsata* does the same both in the colony and in flight, maintaining a brood-rearing temperature of about 33.5 °C (ref. 5).

In tropical forests of Asia, *A. dorsata* nests in colonies of about 40,000 bees on large, single combs suspended in the open from high, breezy supports[6,7]. Some aspects of their thermoregulatory behaviour are well known[5,8]. At 26 °C, the midpoint of the daily ambient temperature, the temperature of the thorax in individual bees in a colony is at least 4.6 °C above that of the ambient air. The temperature excess (T_E) of the thorax at ambient temperatures above or below 26 °C is more than 4.6 °C, a result of thermoregulatory activity for cooling and warming, respectively.

One striking behaviour of *A. dorsata* is mass flight from the broodright colony, in which at least half of a colony's bees fly in gentle arcs up to about 20 m from the comb 5–6 min before returning. We have observed 19 such flights. In each case, the flying bees defaecated, a behaviour resembling cleansing flights in *A. mellifera*. We found 65–100 % of 306 bees in six colonies had faeces before mass flight, but only 0–44 % did so afterwards. The average volume of faeces dumped was 18.3 ± 3.2 μl, weighing 24.6 ± 2.8 mg or 20 % of the total body weight. The mass specific heat of the faeces was 1.85 cal per g °C. With the minimum abdominal T_E of relatively inactive curtain bees of 2.52 ± 0.99 °C, a typical colony would dump 1,850 cal during mass defaecatory flights at ambient temperatures between 28 and 31 °C (ref. 5).

Apart from physical loss of heat in mass flight, reduction of a bee's body mass greatly increases thermoregulatory efficiency. Given a heat coefficient of 0.83 cal per g °C for animal tissue, the amount of energy needed to be lost to reduce the T_E of 5.1 ± 1.1 °C before mass flight to 3.4 ± 1.0 °C afterwards would be 0.22 cal for a bee which has not defaecated (mean weight 123 mg), but only 0.14 cal for one which had (mean weight 98 mg). That is an energy saving of 36 % per participating bee and at least 15 % for the colony. The brood's T_E before and after mass flight was not significantly different.

Mass flight and defaecation occur when thermal stress is greatest. Of recorded mass flights, 60 % occurred between 0900 and 1200 when temperatures rise most rapidly, and another 20 % between 1600 and 1800, when it is often windless. For 33 flights where wind was recorded, 29 occurred in windless periods. The average ambient temperature during 17 mass flights was 29.5 ± 1.0 °C, with a relative humidity of 53 ± 6 %. Gobbetting always occurred before and after mass flights, indicating the continuing need for cooling. The number of gobbetting bees increases as the ambient temperature rises, whether or not mass flight occurs, and gobbetting bees always have lower T_E than do non-gobbetting ones[5].

At air temperatures above 29 °C the bees' T_E rises to and above 36 °C (ref. 5). Under still, humid conditions when heat is not easily lost to the air, temperatures in the curtain and brood rise above toleration (about 37 °C)[5]. Thus, activities which increase efficiency of heat loss, such as mass defaecation, can help avoid the nest temperature reaching a lethal temperature (about 37 °C) under still humid conditions when heat is not easily lost to the air and when the ambient temperature is high.

Ceramics and flocculation

SIR—Kendall *et al.*[1] convincingly demonstrate the importance of particle clusters in limiting the strength of ceramics, but their analysis of the clustering process is incorrect.

The application of nucleation concepts to particle aggregation is open to serious doubt. The external surface energy of a cluster of particles must be less than the total surface energy of the individual particles that make up the cluster, because of particle–particle contacts. This effect would favour cluster formation rather than oppose it, as implied by equation (2) of Kendall *et al.*[1]. In nucleation from solution, the formation of new crystal surface causes an increase in surface energy, which is outweighed by cohesive energy only for nuclei larger than a certain critical size.

Even if the analysis leading to their equation (4) is accepted as correct for clusters, the stationary value is not a dominant cluster size, but a critical size corresponding to a maximum of free energy. Clusters smaller than this size would be unstable, whereas for larger clusters, continued growth is favoured; there should be no dominant size. In practice, shear conditions will impose an upper limit on cluster size, but this aspect does not enter the treatment of Kendall *et al.*.

With this conceptual error removed, there is no longer the apparent paradox that weaker attraction leads to larger aggregates, nor do the speculations concerning biological growth have any foundation. The common-sense view that strong inter-particle attraction leads to large aggregates is still essentially correct.

JOHN GREGORY
Department of Civil Engineering,
University College London,
Gower Street,
London WC1E 6BT, UK

KENDALL REPLIES—We did not claim a formal analogy between nucleation theory and growth of particle clusters. There cannot be a formal analogy because particle aggregates can exhibit a large range of packing and structure whereas crystals are generally of uniform structure.

Our experiments, however, showed that flocculating a suspension of fine particles causes agglomerates to grow, somewhat like crystal growth, whereas vigorous agitation of the suspensions causes the aggregates to break down, unlike crystal growth. Therefore it seemed reasonable to conceive of a balance of growth against breakdown such that clusters of a particular size were produced under the influence of brownian motion.

Such a balance was obtained by considering the free energy of an agglomerate. The outer surface has a positive free energy and so tends to shrink, whereas the contact points within the agglomerate have a negative free energy and so tend to promote growth. The balance between these processes was found by seeking the stationary value of the sum of these posi-

tive and negative free-energy contributions for a perfect agglomerate. Agglomerates of this 'critical' size should neither grow nor shrink, and it is therefore plausible that such agglomerates should be found to predominate over those both bigger and smaller, which should be changing in size. However, as Gregory points out, this is a maximum of free energy and does not correspond to a stable equilibrium configuration, unless there is some as yet undiscovered perturbation that endows stability, as in the argon-clustering experiments of Hoare *et al.*[2].

Gregory states that "the common-sense view [is] that strong inter-particle attraction leads to large aggregates". Such a view is misguided. It is known that weak inter-particle forces lead to large, well structured aggregates. Many experiments have shown that uniform polystyrene spheres, when weakly flocculated, grow into close-packed domains of a few millimetres in diameter displaying opalescence, whereas strong flocculation causes the polystyrene to form small disordered aggregates which do not show opalescence.

Stereo suggestion

SIR—Tucker[1] and Wilson[2] suggest how publishers might alleviate one drawback to 'direct viewing' of stereo-pairs. But, even with years of practice (I acquired the technique unwittingly as a child by staring at repetitive wallpaper patterns), it requires an effort to achieve and maintain the stereoscopic view, and the depth of perception is never so clear as when a stereoscope is used.

Stereoscopes, however, are not easily obtained or cheap, and are too bulky to carry everywhere. I have recently found that a good substitute for a conventional stereoscope is to view the stereo-pair through two flat plastic Fresnel lenses, of the type which are now sold widely as magnifiers for reading. These lenses are not expensive, and two together have the shape and size of a credit card. The optical quality is surprisingly high, and the stereoscopic images are at least as good as those produced by the common folding stereoscope with moulded plastic bi-convex lenses.

Size of aquatic endotherms

SIR—Downhower and Blumer[1] derive a lower size limit of 'aquatic endotherms' of 6.8 kg. This conclusion fails to account for the survival of smaller endotherms, such as adult little blue penguins (*Eudyptula minor* ~1.0 kg)[2] and newborn sea otters (*Enhydra lutris*, 2.0 kg)[3], which spend considerable time in water.

In calculating the lower limit of body size in aquatic endotherms, Downhower and Blumer implicitly assume that the rate of heat loss by an endotherm is controlled by rate of convective heat loss from its surface. Furthermore, their model assumes that when an endothermic homoeotherm enters water, the temperature difference between its surface and the environment remains the same as in air.

These assumptions are not valid for aquatic endotherms, most of which are surrounded by a layer of insulating blubber, fur or feathers that can reduce conductive heat loss so that surface temperature can be maintained close to the environmental temperature. Clearly, the rate of heat loss from the surface by convection in water is controlled by the rate of conduction from the animal's core, through its insulating layer, to the surface. Consistently, the rate of heat loss by aquatic endotherms in water is only 1.6–4.5 times greater than in air[3–5], not 90.8 times, as suggested by Downhower and Blumer.

When realistic values of heat production (metabolic rate), thermal conductance and temperature differences between the core and the aquatic environment are used in appropriate calculations, predicted minimum sizes of aquatic endotherms are much less than the 6.8 kg suggested by Downhower and Blumer, as the empirical evidence requires. Of course, factors other than thermoregulation may limit the sizes of endotherms encountered in nature.

S. INNES
D. M. LAVIGNE

Department of Zoology,
University of Guelph,
Guelph, Ontario, Canada N1G 2W1

DOWNHOWER AND BLUMER REPLY—In calculating the lower limit of body size in aquatic endotherms[1], we adopted the view that the same considerations for the lower limit of body size in terrestrial endotherms[6] would hold for aquatic ones. Aquatic endotherms should be larger than terrestrial endotherms because rates of heat loss are greater in water than in air. We estimated the magnitude of that difference by comparing the convective heat transfer coefficient in air with that in water, holding size, temperature differentials and fluid velocity constant[7]. We coupled that difference with Pearson's estimate for the lower limit on body size in terrestrial endotherms[6], and an allometric equation relating conductive heat loss to body size (in terrestrial endotherms) to estimate the minimum size of a terrestrial endotherm that would remain a competent endotherm in water. Because cetaceans satisfy our requirement of being obligately restricted to water, we compared calculated lower limit of body size for aquatic endotherms with known weights of the smallest cetacean neonates.

Innes and Lavigne suggest there are smaller aquatic endotherms than those we considered, by equating the term 'aquatic endotherm' with any endotherm that spends time in water, rather than restricting it, to competent endotherms obligately restricted to a life in water. Thus, we do not include water shrews (8–18 g)[5], little blue penguins[3] (1–2 kg), harbour seals[4] (22–34 kg, larger than our lower limit), or sea otters[2] (neonates, 2 kg).

Water shrews remain immersed for less than 60 s, dry their wetted fur by grooming, and drop their body temperature by 1–2 °C per 30 s during immersion[5]. In measuring conductive heat loss in little blue penguins, Stahel and Nicol[3] say such measures may not adequately reflect the difficulties of thermoregulation in water: "given the same surface temperature in air and water penguins must withstand a rate of convective heat transfer that is two or three orders of magnitude greater in water than in air (Mitchell, 1974)". Although penguins and seals breed on land, sea otters do give birth in water, and spend much of their lives in water. But their young rest (out of water) on their mother[2], and are weaned at weights greater than 8 kg (J. Estes, personal communication). Their weight at weaning exceeds our predicted lower limit for body size.

Finally, Innes and Lavigne suggest that "realistic values . . . in appropriate calculations" would predict a lower minimum size for aquatic endotherms than we have calculated. But this requires that we ignore the increasingly important roles played by behaviour[5], elevated metabolic rates[3], limited times of immersion[2,5], degree of immersion[2] and hypothermia[5] that are correlated with the severe thermoregulatory complications of invasion of aquatic habitats by endotherms smaller than our calculated lower limit.

It always helps to get an early warning

TPA helps in the early detection of recurrent carcinomas. And early treatment can improve the prognosis and quality of life for your patient.

Rises in the post-treatment levels of serum TPA often precede the clinical symptoms of recurrent carcinomas by as much as six months.*

Serum TPA (Tissue Polypeptide Antigen) can be measured quickly and easily using the Prolifigen®TPA IRMA test.

*Documented for carcinomas of the bladder, breast, lung and genital tract.

The illustration depicts the little Dutch boy Hans Brinker saving his home-town of Haarlem from flooding by sticking his finger into a hole in the dyke. The story was written by Mary Mapes Dodge in 1873.

This legend about the fair-haired hero of Haarlem is one of the world's best known. As with all good fairy-tales, it has a moral: "Don't wait until too late."

Serum TPA measurements: For early and efficient detection of recurrent malignant disease.

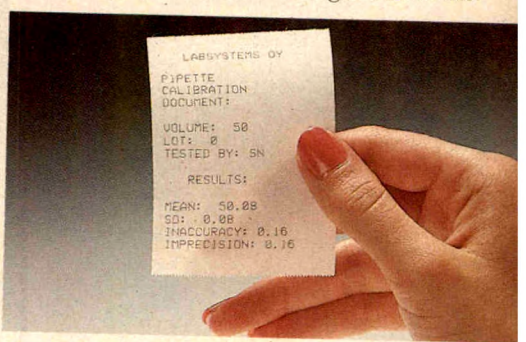
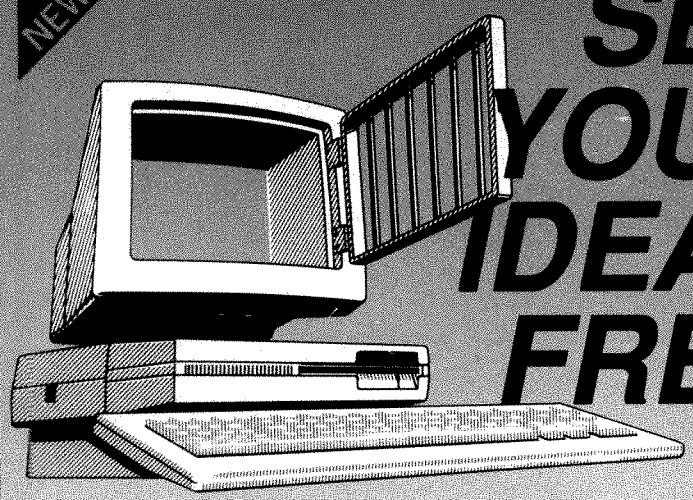
ipette's the answer.

Multichannels now available



From single-channel and multichanne pipettes through to the unique Dilut Labsystems' Finnpipette range of liqu handling equipment offers you the widest choice on the market. The Digitals shown for example go right down to 0.5 µl. All w fully validated accuracy and precision. And because we understand the nature of your work, easy and above all comfortable use. To ensure best results we also supply a full range of quality disposables and acce sories. So whatever field you're working in clinical chemistry, microbiology, genetechn logy – take a tip and start using Finnpipette

Ease of use and comfort – Simply turn t thumb button. It clicks to the desired volur No scales to align. Instead check the clear, easy-to-read digital display and start pipettir Without straining your hand... even after hours of use – thanks to the lightness and c fort common to all Finnpipettes.



Safety and durability – The streamlined unobtrusive tip ejector ensures safety even w biohazardous materials. And also prevents accidental detipping. Durable construction a space-age plastics mean longer bench life.

Accuracy and precision – Each Finnpipette arrives ready for use with its own accuracy validation certificate. What's more, recalibrati can be carried out in your laboratory, quickly and easily.

Full range of quality disposables – for best results we recommend using Finntips. Made from clear contamination-free plastic, they are available vertically packed for added convenience in boxes, or bulk-packed

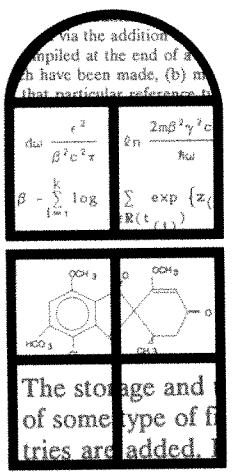
SET YOUR IDEAS FREE



ideaList

ideaList will set you and your data free from the prisons of regular PC database managers.

Designed for lightning-fast, full-text searching of bibliographical references and abstracts, ideaList can help you with all your other loosely-formatted data – notes, results, jottings and the rest.

- Finds any word, date or number in any record – in milli-seconds – no matter how large your database or primitive your PC • Variable-length fields and records – up to about 10 000 words each • Many types of record in one database • 194 ways to search • Omnivorous importing – DBF and Medline, wordprocessor *etc* text files • Flexible exporting (including re-formatting names/initials) • Cross-referencing
- Familiar and complete editor (including clipboard)
- Windows-style screen • Mouse support
- 16-record demo version available on request.

Price: only £120/US$195 – less 20% to academic buyers.

NEW

Vuwriter[II]

Vuwriter[II] is a proper wordprocessor for scientists: fast, full-featured and IBM-compatible, yet as simple as ABC. Drop-down menus, helpful dialog boxes and mouse support will have you running Vuwriter's slick editor, equation layouts and scientific fonts in next to no time.

- Full wordprocessor command set • Maths/Greek fonts
- Windows-style, WYSIWYG display • 15 levels of sub/super-script • Vertically aligned proportional-space text
- Varying margins within pages • Two files on screen
- Macros • Mailmerge • Spelling checker
- Epson/HP/PostScript support.
- Demonstration version available on request.

Price: £425 – less 20% to academic buyers.
(Apply for separate prices in USA/Canada.)

Vuwriter[II] is a product of Vuman Computer Systems Ltd.

FITS ANY FUNCTION TO EXPERIMENTAL DATA

Regression

Regression now makes it easy for you to fit any function to your research data, on either a PC running MS-Windows or an Apple Macintosh.

You enter the function (model) that you wish to fit as a simple, natural language equation. The function can be any that you define: common arithmetical/transcendental functions are available, including logarithmic, exponential and trigonometric. You can include up to 10 parameters and 100 data points, and weight residuals in different ways to suit the error structure of the data.

You can store models and data, and retrieve and edit them. Examples distributed free on disk include hyperbolic functions, mono- and bi-exponential functions and Rot/Cot curves. The documentation includes discussion of optimization strategies and the strengths of different algorithms.

- Demonstration version available on request for Macintosh or PC; requires MS-Windows to run on a PC.

Price: £150/US$225 – less 20% discount to academic purchasers.

Use coupon on left.

Trademarks/owners: Apple and Macintosh/Apple Computer Inc; MS-Windows/Microsoft Corporation

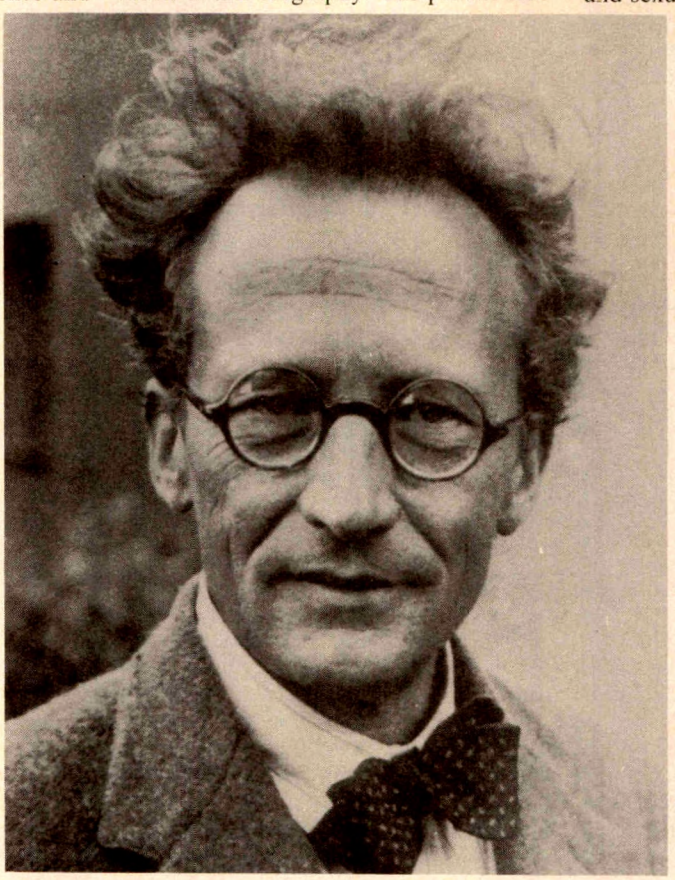
Physicist and philanderer

P. W. Atkins



Schrödinger: Life and Thought. By Walter Moore. *Cambridge University Press: 1989. Pp.513. £25, $39.50.*

WHAT is life? That Erwin Schrödinger knew the answer, in more ways than one, is revealed to us in this biography. He suffered the deprivations of two world wars, and had the euphoria of the award of a Nobel prize; he enjoyed a *ménage* of at least *trois*, captivated and hunted young women, and through his intelligence and charm captured them. He felt himself to be almost a component of the cosmic being, and that the world was his oyster. But he was flawed in conventional earthly terms, for his behaviour, charitably interpretable as naïveté, could be cowardly, hurtful and ungrateful. He is fortunate to have the admiring biographer that Walter Moore has proved to be.

Schrödinger arrived in the world and left it in Austria, in 1887 and 1961 respectively, and we are not long gone from his centenary year. He was born into the political turmoil that repeatedly slashed the face of Europe, but as if in compensation enjoyed the comparable but happily more abstract turmoil that was the mark of physics over the same period. His life spanned the discovery and maturing of modern physics, and he contributed notably to a formulation of quantum mechanics that is still the more widely used and which is normally encountered first.

For a summary of a life in a nutshell — and in many respects Schrödinger's life was bigger than any familiar nut — it is enough to remark that he grew up among the classical physicists of Vienna, endured the deprivations of that city in the First World War, and went on to propose his wave equation in an outburst of creative energy in the mid-1920s while holding a chair in Zürich. After fittingly succeeding Max Planck in Berlin in 1927, he (a Protestant) escaped to Oxford in 1933. But he foolishly returned to the heart of Nazi-raddled Graz, only to find it necessary to leave a year or so later for Oxford again and later Ghent. Meanwhile he had been pursued by De Valera, whose ambitious and admirable scheme to found an Institute for Advanced Studies in Dublin came to fruition despite the privations to which Eire was subject. Schrödinger was appointed its first director; there he stayed from 1940 to 1956 in one capacity or another, but in the end was drawn back to his motherland, to die in the Tyrol.

Such was Schrödinger's public *vita*, the spring of his awards, the Nobel prize in 1933, and his immortality in physics. Yet there was a private side that occupies much of this biography. The private side sparkles from the jacket photograph and from the more permanent collection of images within. Here we see not the mathematically sophisticated but sometimes physically misled creator of new worlds and extender of the domain of physics into the realm of life, but the urbane, handsome, witty, wooer of women of all ages, the younger the better. Nymphets, the young unattached, and wives all came within his questing sexuality, and more than one emerged impregnated as the mother of his child. His occasionally unrequited quest for love (or, at least, active loving) began before his main work was done. But with the confidence that came with success, fame spurred him to a greater exuberance, and in discarding conventional morality he also discarded sombre jackets for Tyrolean suits, much to the perturbation (on both counts) of those of stuffier frames of mind. All this was done against the background of his stolid wife Anny's active complaisance. It is fitting that in the days before his death he appears to have recognized the freedom and — in her own way — the love and faithfulness that she brought to their unconventional marriage.

Erwin Schrödinger — "literally felt himself at one with God".

Yet, skilled mathematician, lucky physicist and engaging philanderer that he was, there was also a darker, more unpleasant and (to the partly informed at least) reprehensible side to Schrödinger's demeanour and activities. Professional and sexual success had gone to his head, and in some respects Schrödinger considered himself to be God. Women were his admiring angels, and only rarely was his self-felt superiority brought into question by some who could cut him down to size. With his Vedantic view of the cosmos he literally felt himself at one with God, and presumably felt himself a particularly witty protuberance into reality of an underlying unity. Hubris, or just plain thoughtlessness, led to ill treatment of those who had helped him. Lindemann, who had done so much to induce ICI to provide funds to support Schrödinger in England, was a particular, probably unconscious, target of this kind of abuse and ingratitude. Others suffered too, perhaps Anny most of all.

Schrödinger also appears to have been a coward, and I do not think that the aura of naïveté that is widely claimed for him (though not everywhere in this quite well-balanced book) is enough to excuse his famous grovelling letter written in Graz in 1938:

> In the midst of the exultant joy which is pervading our country, there also stand today those who indeed partake fully in this joy, but not without deep shame. . . . I make this confession willingly and joyfully. I believe it is spoken from the hearts of many, and hope thereby to serve my homeland.

The newspaper that published the letter leapt on the support it most definitely appears to give for the Nazis. His excuse was the need to remain free, and hence the concomitant need to resort to duplicity. That may be so, for Schrödinger was morally shallow. The letter pleased few, however, and he lost Einstein's respect. That loss was a severe sadness, for Schrödinger was pleased that Einstein, his earthly hero, had regarded him as an intellectual brother as the two struggled vainly for a unified field theory after their powers had fallen from their prime.

I find it difficult to judge whether Schrödinger was truly great — as a scientist; as a man he was no conventional saint. I suspect that he was a great man of the second division. In his early work his mathematical skill was alloyed with a baser metal, and the contaminant did not allow him to judge the physical plausibility of everything he did. He was perfectly in his element, mathematical manipulation, when dealing with his wave equation, and the sunburst of solutions that accompanied its first publication. Yet that moment in his life had no precedent and was not to be repeated, despite some notable contributions to relativity. He was certainly farsighted in his pushing for physics to be extended to form the foundations of biology, but his inclinations to the tenets of Eastern religions (as far as an orthodox scientist can judge) acted as a cataract to dim his vision. He also wrote poetry (particularly to pull in a harpoon that had been let slip to achieve an amorous conquest); again, as far as I can judge from the numerous examples in the text, he was not a poet.

Physics is certainly the better for Schrödinger's existence, and that is the essence of true immortality. Dublin was also undoubtedly intellectually enriched by his lengthy sojourn there and his early moulding of its famous Institute, and that is a valuable contribution to civilization. Some friends, I suspect, have been left not a little poorer; but in the great accounting, perhaps friends don't count, especially if you think you are God Almighty. After all, what is life? □

Light work

O. S. Heavens

The Fabry–Perot Interferometer: History, Theory, Practice and Applications. By J. M. Vaughan. *Adam Hilger: 1989. Pp. 583. £60, $130.*

UNTIL the arrival of the laser, optics tended to be dismissed as one of the bits of physics that was essentially completely dealt with. James Clerk Maxwell had after all given a comprehensive and fundamental description of light — a mere slice of the broader spread of the electromagnetic spectrum — which accounted elegantly for all the known phenomena such as propagation, interference, diffraction and scattering. Although the need to recognize the quantum character of light (and the wave character of matter) somewhat disturbed the serenity, there seemed no need to revise the essentials of Maxwell's ideas, nor to expect any dramatic developments.

Nobel prizes flowed steadily in the direction of particle physicists — until 1964. In that year the award of the prize to Townes, Prokhorov and Basov signalled the return of optics to the frontier region. Following the notions outlined by Einstein in 1917, which were exploited in the microwave region of the spectrum in 1954 (maser), the laser appeared in 1960 and rapidly transformed most areas of optics. Within a few years, many of the quantities associated with 'ordinary' light sources had changed by many orders of magnitude, especially intensity, brightness and monochromaticity. By now there are few disciplines in the sciences and engineering that have not been profoundly affected.

Both the operation of the laser and many of its remarkable applications are based on the Fabry–Perot interferometer, a deceptively simple device consisting of two flat, partly silvered glass plates rigidly held parallel to one another. First described by Perot and Fabry in 1899, the device immediately made it possible to determine the wavelength of spectral lines to an unprecedented accuracy — better than one part in a million. The historical background provided in this book leaves one fascinated and full of admiration for the thoroughness and ingenuity of the experimenters at the turn of the century.

The step to the laser was in a sense very simple. Take a pair of Fabry–Perot plates, pull them apart, and place a discharge tube (say a neon sign) in between them. (This was in fact tried by Tolansky in 1956 — not to try to make a laser but to "see what happened". Nothing did.) When things are properly adjusted an intense light beam, less than a millimetre in diameter, streams out of the system. The apparent simplicity belies the great usefulness of a light beam which has very regular oscillations (coherence), is of high intensity and has an extremely well-defined wavelength (colour).

Dr Vaughan gives many examples of the dramatic contributions which the laser, in conjunction with the Fabry–Perot interferometer, has made to the fields of atomic spectroscopy, astronomy, astrophysics, light-scattering, metrology, infrared detection and many others. In fact, the content of the book is much broader than the title suggests, in that the 70 or so pages of appendix bring the reader thoroughly up to date with the whole range of the many associated techniques needed to exploit this remarkable device to the full. The book will be enjoyed at many levels — for its historical interest, as an overall perspective of some 25 years of exciting developments and as a valuable source of information on the state of the art. □

Opiates for the people

Peter Newmark

Brainstorming: The Science and Politics of Opiate Research. By Solomon H. Snyder. *Harvard University Press: 1989. Pp. 208. $22.50. To be published in Britain next month, £17.95.*

PRESIDENT Bush's administration has just declared war on drugs, and wants to spend an extra two billion dollars next year in controlling the problem. Vast sums will go into law enforcement, prison space, education, workplace inspections and media campaigns. Half a billion dollars in all will be set aside to fight the battle against the trafficking barons in South America and in providing protection for the legal officers who stick to their unenviable jobs. The same amount will be spent on increasing and improving drug treatment, which is particularly poor for cocaine users.

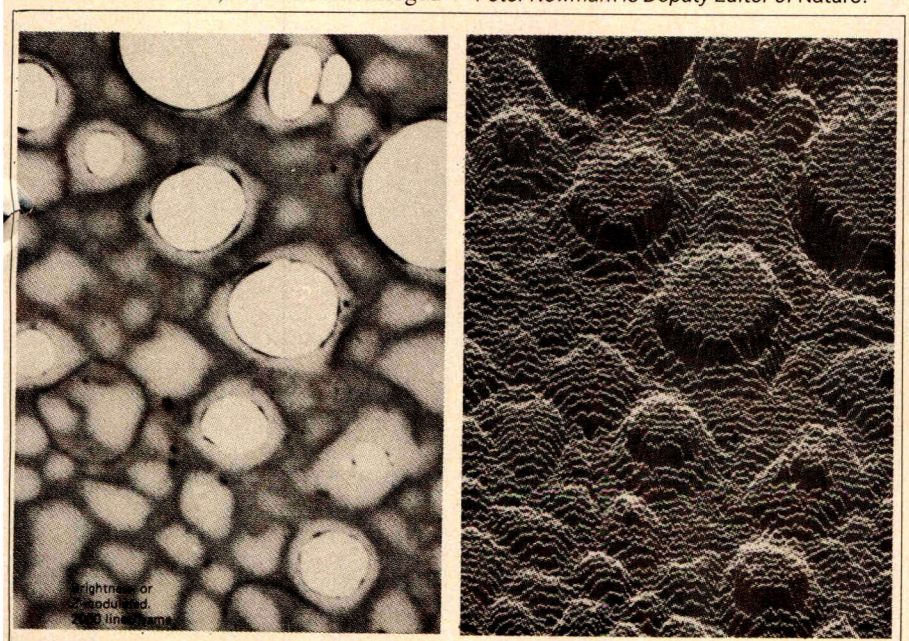
How much extra is to be spent on biomedical research, which might lead to completely new approaches to the prevention and treatment of drug addiction? Nothing, as far as can be told. Could it be that the amount is so little as not to warrant a mention? Or that the swashbuckling image is so important to those who formulate strategy that the scientists simply did not stand a chance? Or is it that the President was given a pre-publication copy of Solomon Snyder's thoughtful new book, but gave it too narrow a reading?

It was Richard Nixon's war on drugs, launched in 1971 to counter an epidemic of heroin addiction, that also launched Snyder into opiate research. At that time, he "hardly knew heroin from horseradish" but did know Jerome Jaffe, the man that Nixon put in charge of an office created to coordinate drug-abuse programmes. Jaffe and Snyder were both trained as psychiatrists in the 1960s and had become interested in the biological approach to mental illness, so Snyder's suggestion that some money should be spent on drug research centres received a sympathetic hearing. But such was the opposition to spending on research rather than treatment, that it was many months before Snyder found himself applying for a share of the two million dollars to be spread among six research centres.

Snyder was convinced that his first goal should be to establish the site of action of opiates and to identify the cell-surface receptor through which he was sure they acted. But suspecting that such a project would be thought too bold by his peers, he adopted the well-known ploy of applying for funds to carry out research on

amphetamines that he had already more or less completed, and then, having obtained funds, switching tracks. By summer 1972, Snyder had set Candace Pert, a self-confident graduate student, the task of identifying the opiate receptor.

Nine months later, to coincide with publication of the paper that told of their success, Snyder found himself facing the world's press. The reason was this. Snyder's funds came from a specific political initiative and the White House — as its counterparts in most places at most times — tended to the view that nothing of value comes quickly enough out of basic research to reflect well upon those who have invested in it. Sensing that the discovery of the opiate receptor was an exception, the director of drug-abuse research at the National Institutes of Health set up a press conference.



The discovery indeed led to vastly simplified tests for new agonists and antagonists of the receptor, that might lead to improved treatments for heroin addiction. It also enabled the distribution of the receptor in the brain to be mapped to the pain pathways. And when, in 1975, Hans Kosterlitz and John Hughes in Aberdeen became the first to characterize some of the peptides that are natural ligands for the receptor, and so the body's own painkillers, the way seemed set for pharmaceutical companies to produce a new generation of analgesics. Based on the natural compounds, which were surely not addictive, they would replace morphine and its relatives.

There was a catch, however. It emerged that the only reason that the natural ligands for the opiate receptor are not addictive is that they are very short-lived. For therapeutic purposes, the pharmaceutical companies had to produce long-lasting analogues. These proved to be addictive and have never reached the market. Thus a narrow reading of Snyder's story might confirm the view that pouring money into basic research seldom yields immediate returns of the kind that would satisfy politicians.

Snyder writes well. He is adept at explaining technicalities and is forthcoming about his own motivation and shortcomings. He confesses that his research has often been influenced as much by the need to stake out territory, establish priorities and defend reputations as by any noble notion of furthering the cause of science, and he admits to being a colossal klutz when it comes to experiments. Consequently, he never does them himself, instead leaving them to his ten or so graduates and postdocs, none of them permanent. Obviously caring about the well-being of his students, he nevertheless cannot be easy to work for.

In 1978, the Lasker Awards, awarded annually in the biomedical sciences, were given to Snyder, Kosterlitz and Hughes. Not surprisingly, Pert was less than pleased by her exclusion and was not reluctant to say so. One would have expected the ambitious Snyder to mention the prize, and the psychiatrist Snyder to explore the circumstances. Strangely, there is no word from either. □

Peter Newmark is Deputy Editor of Nature.

Highlighting takes on a new meaning when special image-processing techniques are applied to electron micrographs. On the left is a standard micrograph (brightness, or *Z*, modulated) of a defective carbon film: perforations and thin patches are brighter than the surrounding film. On the right, the intensity information is used to modulate the vertical deflection of the left-to-right raster lines (*Y*-modulation), so that the eye sees it as topography on a surface. These images are taken from the new, amended paperback edition of *The Principles and Practice of Electron Microscopy* by Ian Watt, published by Cambridge University Press.

Giving reasons

Alan Holland

Animal Consciousness. By Daisie Radner and Michael Radner. *Prometheus: 1989. Pp. 253. $39.95. To be published in Britain next Spring, £29.95*

Consciousness, it seems, is an embarrassment to scientists and philosophers alike. The neurologist R. J. Joynt declares that he has been trained not to deal with it. The philosopher Patricia Churchland would have it as on the way to obsolescence.

Animal consciousness, then, is an embarrassment on legs. For it lacks even the accreditation of first-person testimony. In the latest of a small crop of books on the subject which have appeared this year, Daisie and Michael Radner stand up for animal consciousness as an aspect of animal life which any thoroughgoing evolutionary ethology should recognize. Philosophers themselves, the Radners have done their scientific homework and can be read with profit by anyone involved in the study of animal natures. Their purpose is to uphold the legitimacy of both scientific and philosophical study of animal consciousness, by clearing away some of the stumbling blocks to that study.

Chief among the stumbling blocks is cartesian metaphysics, which sees human beings as "composed of a soul and a body". In itself the human body is but a "machine made of earth", and animals are assigned the same status as human bodies, lacking a mind or soul. In the first half of the book — "The Breakdown of the Beast–Machine" — the Radners show how the resources of the cartesian tradition, even granting all its main assumptions, fail to disprove animal consciousness. Contrary to what Descartes maintained, the actions of some animals can be construed, and in some cases perhaps can only be construed, as employing reason — provided only that some middle ground is recognized between perfect reason and no reason at all. Sensation and the powers of communication are denied to the animals only on the unfounded and exclusive presumption that they have to involve pure thought. Of particular interest is the Radners' discerning of a dual notion of consciousness in Descartes — roughly, a reflective and a non-reflective awareness — which is actually conducive to the recognition of animal consciousness rather than the reverse. Their reading of Descartes is plausible and they are no doubt right to suggest that received accounts of his concept of mind are distorted by the undue attention that has been paid to the rather special preoccupations of the *Meditations*.

The Radners claim that, in the light of the theory of evolution, the existence of human consciousness makes the existence

of animal consciousness probable. If they are correct, then the persistence of the cartesian legacy in the period after Darwin —the subject of the book's second half — is all the more surprising. Perhaps their claim is overstated. Arguing from the case of one species seems mighty risky. And perhaps the significance of consciousness is magnified in human eyes so that we wrongly think it must be expected to exist in many other animal forms. The authors' preferred explanation points to the failure — for example, of the early comparative psychologists — to find an *explanatory* role for consciousness, a place in the causal network. To this they add the positivist-inspired doubts about the testability of ascriptions of conscious states, and some powerful reworking of Descartes' doubts about the capacities of animals for communication and reasoned action. The Radners confront these new and renovated problems with resolution and ingenuity. Their re-evaluations of three prominent examples of alleged mindlessness in animals are among the best things in the book which, overall, is well constructed and adroitly argued.

My chief criticism concerns what they haven't done, or haven't done thoroughly enough. Having argued that 'there *is* something it is like to be an animal' — to use Tom Nagel's illuminating phrase — the next question is how we are to discover *what* it is like. Although they recognize the problem, the Radners don't take us very far along this road. In the matter of whether it is better to be a dissatisfied human being or a satisfied pig, John Stuart Mill was confident that human beings know both sides of the question.

Although they must agree with Mill in principle, the Radners rightly observe that matters are not that simple. Because desires are integrated differently in a pig, they say, and because pigs have "desires of their own" (they don't say how they know this), the comparative judgement is problematic.

In another case involving attempts to communicate with primates, they observe, reasonably enough, that the question asked of the gorilla, Koko, "Where do gorillas go when they die?" is a human question. For Nim the chimpanzee, who had tested new teachers by aggressive displays, they suggest "Me boss you?" as a more appropriate reflection of Nim's world. Yet, it seems to me, they may be seriously underrating the difficulties of entering the porcine or simian worlds. It is within the human world that Nim's response is construed as aggressive. It seems rash to assume that the response bears that construction in the rather differently structured world of the chimpanzee. In problems such as these lie the fascination and challenge of the study of animal consciousness which, in a suitably sensitive and disengaged form, seems barely to have begun. □

Out of chains

John Bell

PCR Technology: Principles and Applications for DNA Amplification. Edited by Henry A. Erlich. *Stockton, New York/ Macmillan, London: 1989. Pp.246. Pbk $19.95, £15.95.*

COMPILING a book on a technique that is developing rapidly presents considerable difficulties. It is perhaps for this reason that almost three years have passed without a serious attempt being made to assemble a volume on the polymerase chain reaction (PCR). This technique, which permits the *in vitro* amplification of specific DNA sequences, is now one of the most powerful tools available to molecular biologists. New applications and adaptations have been appearing so quickly that even journals are having a difficult time keeping up.

No group is more suited to review the field than Henry Erlich and his colleagues at Cetus. It was from their laboratory that the idea arose and was systematically and rapidly developed. In this book, the Cetus group and their co-authors are extremely successful in conveying both the theoretical and the applied aspects of PCR.

An initial section on basic methodology and its application provides a clear yet detailed chapter describing protocols and conditions for PCR and an excellent chapter on the polymerase enzyme obtained from *Thermus aquaticus* (Taq). Through its stability at high temperatures, Taq has permitted the technique to be automated and hence widely applied. Although Cetus has a substantial commercial interest in both the enzyme and a PCR thermal cycler, there is little direct promotion of their products — except perhaps for the criticism of water-cooled thermal cyclers because they waste water and are therefore ecologically unsound!

The second part of the book is devoted to evaluating applications. Modifying DNA, cloning new genes, detecting mutations, inverted PCR and numerous other variations on the basic technique are described. Not all of the modern adaptations are included — anchor PCR, quantitation (and its problems) and CA repeat mapping are not discussed. But that was inevitable; not only are things moving so fast, but a comprehensive review of research applications would have made the book unmanageable.

The field where PCR is most likely to have its greatest impact is human genetics, and the contributors to the third section, "Medical Applications", are mostly drawn from this camp. As well as chapters on genetic diagnosis, HLA polymorphism and oncogenes, there are discussions of forensic applications and detection of infectious disease. These latter two chapters are likely to be of special importance in the future.

A notable feature of the book is its emphasis on practical aspects of the technique — every chapter is written by innovative scientists and is accompanied by detailed protocols. In particular, careful attention is paid to contamination. This failing of PCR is related to its greatest strength, because extreme sensitivity commonly leads to the spurious amplification of DNA contaminants. The problem is thoroughly addressed by the authors, and if their advice is taken it can clearly be contained.

This volume is long overdue. It lives up to all expectations, and will be valuable to both the neophyte and the experienced PCR scientist. The only recommendation I can add is that it should be purchased and read quickly, for if the field continues to move as quickly as it has the authors will be writing the next edition early in 1990. □

John Bell is in the Molecular Immunology Group, Institute of Molecular Medicine, John Radcliffe Hospital, Headington, Oxford OX3 9DU, UK.

PCR and more besides

'LONG-awaited' is the tag publishers on occasion apply to their books that appear months, even years, after they were first announced — and, it turns out, to indifferent public reaction.

That should not be the fate of the long-awaited second edition of *Molecular Cloning: A Laboratory Manual*, even though molecular biologists are still waiting for it. First announced for publication by Cold Spring Harbor Laboratory Press in October 1988, the second edition will appear next month.

The reason for the delay is that the decision was taken to include the developments of 1988 and early 1989. Principal amongst these is PCR technology, the subject of a new chapter. Overall, the material has been split into three volumes, and although the authors remain the same the second edition becomes Sambrook *et al.* rather than Maniatis *et al.*

Sambrook *et al.* will face much more competition than they did before (for some of the contenders see *Nature* **333**, 309; 1988). But the work's biblical status and its remarkable price ($97) will no doubt make it a compulsory purchase. TL

NEW FROM OXFORD

NEW EDITION

Gel Electrophoresis of Proteins: A Practical Approach

Second Edition

Edited by **B. D. Hames and D. Rickwood**

Contents: One dimensional polyacrylamide gel electrophoresis; Isoelectric focusing; Two-dimensional gel electrophoresis; Immunoelectrophoresis; Peptide mapping; Appendices.

0 19 963074 7, 250 pp., illus., spiral bound, IRL Press, January 1990 £27.00
0 19 963075 5, paperback £18.00

Solid Phase Peptide Synthesis: A Practical Approach

E. Atherton and R. C. Sheppard

Contents: Peptide synthesis—An introduction; Solid phase peptide synthesis—The Merrifield technique; Fmoc-polyamide solid phase peptide synthesis—General principles; The solid support; Fluorenylmethoxycarbonyl amino-acids; Linkage agents; Activation procedures; Instrumentation for Fmoc-polyamide solid phase synthesis; Analytical and monitoring techniques; Reaction procedures and operating techniques; Resin cleavage and purification techniques; Illustrative synthesis.

0 19 963066 6, 250 pp., illus., spiral bound, IRL Press, October 1989 £27.00
0 19 963067 4, paperback £18.00

Fermentation: A Practical Approach

Edited by **B. M. McNeil and L. M. Harvey**

Contents: Setting up equipment for laboratory fermentation; Laboratory fermentation; Innoculum preparation and fermenters; Fermentation modelling; Fed batch and continuous culture; Electrodes for fermentation; Instrumentation and control; Sterilisation; Animals cell culture.

0 19 963044 5, 276 pp., illus., spiral bound, IRL Press, November 1989 £29.00
0 19 963045 3, paperback £19.00

Proceedings of the Sixteenth Symposium on Nucleic Acids Chemistry

Edited by **Hiroshi Takaku**

Contents: Thirty-nine papers were presented by distinguished Japanese scientists, abstracts of which are presented in this volume. The subjects covered include the identification of the mutation responsible for the beta-thalassemia, the DNA marker linked to congenital malformations, and effects on DNA of antitumour antibiotics.

Nucleic Acids Symposium Series No. 21

0 19 963127 1, 150 pp., illus., paperback, IRL Press, October 1989 £30.00

Medical Mycology: A Practical Approach

Edited by **E. G. V. Evans and M. D. Richardson**

Contents: General guidelines on laboratory diagnosis and antifungal monitoring; Direct microscopy; Culture and isolation of fungi; Identification of the agents of superficial mycoses; Identification of yeasts; Identification of the agents of subcutaneous mycoses; Identification of the agents of systemic mycoses; Identification of common culture contaminants; The maintenance and preservation of fungi; Serological tests; Methods of antifungal drugs; Histopathology.

0 19 963010 0, 318 pp., illus., spiral bound, IRL Press, 1989 £37.50
0 19 963011 9, paperback £25.00

NEW EDITION

Gel Electrophoresis of Nucleic Acids: A Practical Approach

Second Edition

Edited by **D. Rickwood and B. D. Hames**

Contents: Gel electrophoresis of RNA; Gel electrophoresis of DNA; Pulsed field electrophoresis of DNA; two dimensional gel electrophoresis of nucleic acids; gel retardation analysis of proteins binding to DNA and RNA; Nucleic acid footprinting; Electrophoresis of nucleoproteins; Appendices.

0 19 963082 8, 272 pp., illus., spiral bound, IRL Press, February 1990 £27.00
0 19 963083 6, paperback £18.00

Electrophoretic Studies on Agricultural Pests

Hugh D. Loxdale and J. Den Hollander

Includes: Electrophoresis in agricultural pest research—A technique of evolutionary biology; Electrophoretic studies: Perspectives for population biology; Genetic studies of species differences and their relevance to the problem of species formation in *Drosophila*; the complexities of host races and some suggestion for their identification by enzyme electrophoresis; Population genetics studies of fruit flies of economic importance, especially medfly and olive fruit fly, using electrophoretic methods; Host-associated differentiation in armyworms (Lepidoptera: Noctuidae): an allozymic and mitochondrial DNA perspective; Other topics.

Systematics Association Special Volumes No. 39

0 19 857710 9, 400 pp., illus., Clarendon Press, December 1989 £65.00

Nucleic Acids Sequencing: A Practical Approach

Edited by **C. J. Howe and E. S. Ward**

Contents: Contributors; Abbreviations; Introduction; The use of single-stranded DNA phage in DNA sequencing; Sequencing single-stranded DNA using the chain-termination; Troubleshooting in chain-termination DNA sequencing; Sequencing of double-stranded DNA; Maxam and Gilbert sequencing using one metre gel systems; RNA sequencing; Computing; Automated DNA sequencing.

0 19 963056 9, 250 pp., illus., spiral bound, IRL Press, November 1989 £29.00
0 19 963057 7, paperback £19.00

Liposomes: A Practical Approach

R. R. C. New

Contents: Introduction; Preparation of liposomes; Liposome characterization; Covalent attachment of proteins to liposomes; Physical methods of study; Liposomes in biological systems; Appendices: I. Miscellaneous methods; II. Manufacturers and suppliers; III. Standard texts of liposomes and phospholipid membranes.

0 19 963076 3, 272 pp., illus., spiral bound, IRL Press, January 1990 £27.00
0 19 963077 1, paperback £18.00

The NMDA Receptor

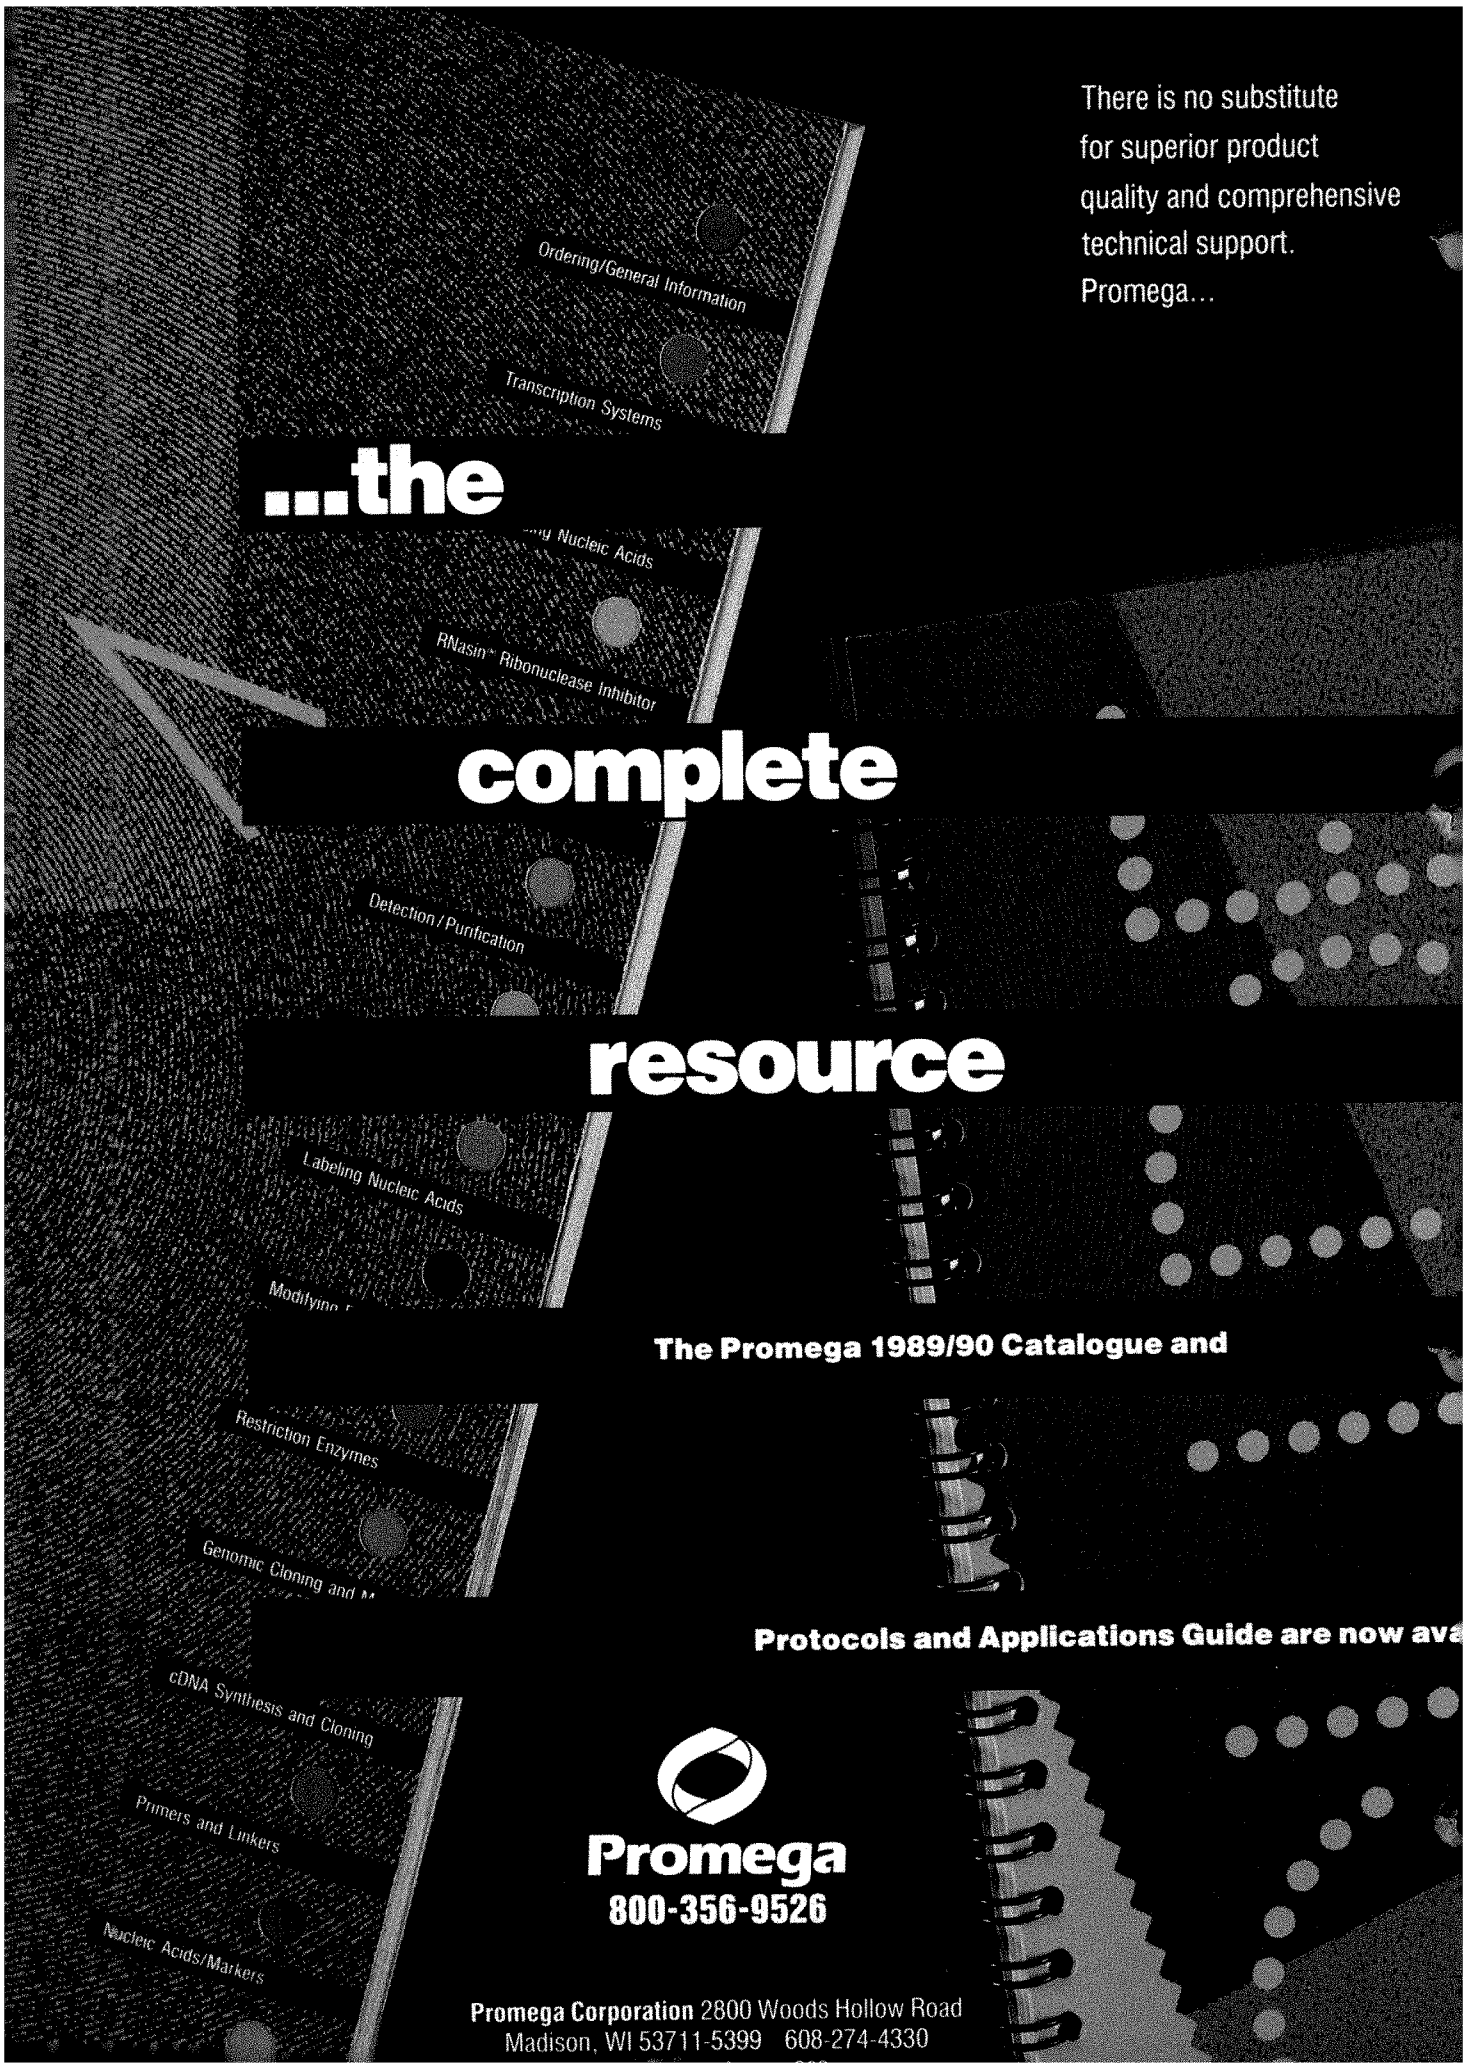
Edited by **G. L. Collingridge and J. C. Watkins**

Contents: The NMDA receptor concept: origins and development; Agonists and competitive NMDA antagonists; Non-competitive antagonists of N-methyl-D-aspartate; Regional variation in NMDA receptor properties; *In vitro* preparations of spinal cord or brain which can be used for grease gap electrical recording of excitatory amino acid action; NMDA receptors in synaptic pathways; The role of NMDA receptors in synaptic integration and the organization of complex neural patterns; The NMDA receptor, its channel, and its modulation by glycine; NMDA receptors and long-term potentiation in the hippocampus; NMDA receptors and developmental plasticity in visual neocortex; Other topics.

0 19 963125 5, 200 pp., illus., paperback, IRL Press, December 1989 £25.00

Medical Bacteriology: A Practical Approach

Edited by **P. M. Hawkey and D. A. Lewis**



Contents: Bacteriology of urine; Sterile body fluids; Respiratory tract; Tissue infections; Intestinal disease; Susceptibility testing; Antibiotic assays; Record-keeping; Quality control; Nosocomial infection; Epidemiological techniques for the investigation of bacterial infections.

0 19 963008 9, 344 p., illus., spiral bound, IRL Press, October 1989 £38.00
0 19 963009 7, paperback £25.00

POWER FROM THE WIND

This new 26 minute video from the Central Electricity Generating Board examines the centuries old challenge of harnessing the power of the wind. Presented by David Bellamy and shot on location in Barbados, Holland, the Orkneys and mainland Britain, it considers the historical use of the wind's energy and the current revival of interest in wind power to produce electricity.

David Bellamy looks at the development of 'wind-turbines' and at the part that they can play in electricity production, both in small island communities and in complex industrial societies. He also considers plans in Britain to construct three 'wind farms', and the environmental impact of wind power technology.

THE PERFECT BIND

When did Nature cover Science in Switzerland?

Where are the latest research results about AIDS?

What's the latest development in superconductivity?

Have you noticed that you never manage to lay your hands on that issue of Nature when you need it most!

For a very reasonable cost, why don't you save time and effort by investing in a set of smart and durable Nature binders.

	Single binder	Set of 4	
UK	£5.25	£16.00	Prices include
Rest of World	£7.75	£22.00	postage and packing

Never again will you be at a loss for that vital information. Each binder holds approximately 16 issues and makes sure that key knowledge is kept at your fingertips.

Complete the order form and in no time your copies of Nature can be kept in order.

Please send me_____Nature binders

☐ I enclose a cheque for £_____ made payable to Nature

☐ Please charge my credit card for £_____
☐ Visa ☐ AMEX ☐ Access
☐ Diners Club

A New Dimension
in Light Microscopy

A better insight into living cultures: Zeiss Axiovert

One impressive example: the Axiovert 405 M Inverted Photomicroscope with two integrated cameras which meet even the most critical demands on photomicrography.
ICS optics guarantee perfect, bright images - even with long working distances. The integration of all contrast-enhancing techniques means superb operating convenience - with no reduction in performance. Furthermore, the Axiovert inverted microscopes form the efficient basis of the "motorized microinjection" workplaces and the computer-controlled "AIS Automated Injection Systems".

Axiovert - the inverted microscopes from Zeiss: they open up totally new horizons for researchers in biology and medicine.

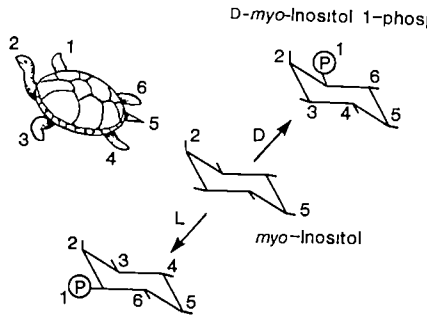
Inositol phosphates and cell signalling

Michael J. Berridge & Robin F. Irvine

Inositol 1,4,5-trisphosphate is a second messenger which regulates intracellular calcium both by mobilizing calcium from internal stores and, perhaps indirectly, by stimulating calcium entry. In these actions it may function with its phosphorylated metabolite, inositol 1,3,4,5-tetrakisphosphate. The subtlety of calcium regulation by inositol phosphates is emphasized by recent studies that have revealed oscillations in calcium concentration which are perhaps part of a frequency-encoded second-messenger system.

KNOWLEDGE of the phosphoinositides and their role in cell signalling has expanded enormously since we reviewed this field five years ago[1]. Stimulation of cell-surface receptors initiates hydrolysis of a membrane-bound inositol lipid, which produces at least two second messengers—diacylglycerol (DAG) and inositol 1,4,5-trisphosphate ($Ins(1,4,5)P_3$). These messengers are generated by a membrane transduction process comprising three main components: a receptor, a coupling G protein and phosphoinositidase C (Figs 1 and 2). DAG acts by stimulating protein kinase C (ref. 2), whereas $Ins(1,4,5)P_3$ releases calcium from internal stores[1,3]. These pathways form the cornerstone of an ubiquitous transduction mechanism now known to regulate a large array of cellular processes including metabolism, secretion, contraction, neural activity and cell proliferation[1-7]. The second messenger role of DAG has been reviewed recently[2], and here we concentrate on the contribution of the inositol phosphates.

An enormous number of inositol phosphates have now been found in eukaryotic cells, and details of some of the metabolic pathways linking them have been elucidated[10-12] (summarized in Fig. 1; see panel on right for details of inositol phosphate numbering). A myriad of suspected or postulated functions have been ascribed to them, some of the more plausible are mentioned briefly below, but here we concentrate principally on the messenger functions of $Ins(1,4,5)P_3$ and related compounds, and particularly on their involvement in the generation of intracellular calcium signals. As more and more studies are made on single cells, it is becoming apparent that the phosphoinositide transduction system is highly organized in both space and time, and we present a spatiotemporal model that may help to unify the emerging ideas about intracellular calcium signalling.



Multiple calcium pools

When cells respond to calcium-mobilizing agonists that act through the hydrolysis of inositol lipids, they draw upon both intracellular and extracellular sources of calcium. Although the latter remains constant, the size and distribution of the internal pools is highly variable. $Ins(1,4,5)P_3$ releases calcium from a non-mitochondrial pool which has characteristics which suggest that it is the endoplasmic reticulum (ER)[13], but only part of this pool seems to be $Ins(1,4,5)P_3$-sensitive; on average $Ins(1,4,5)P_3$ releases approximately 30–50% of the calcium taken up by the non-mitochondrial pool of calcium, the remainder of which can be released by calcium ionophores. This evidence implies that the $Ins(1,4,5)P_3$-insensitive pool is a separate membrane compartment which may have distinct calcium-pumping characteristics[14].

The anatomical location and identity of the $Ins(1,4,5)P_3$-sensitive and -insensitive pools are uncertain. Supattapone *et al.*[15] have purified a protein of relative molecular mass 260,000 (260K) that is thought to be the $Ins(1,4,5)P_3$ receptor. Immunocytochemical studies using a specific antibody on Purkinje cells (which have an extraordinarily high receptor density) reveal that this receptor is localized on the nuclear envelope and on parts of the ER, particularly near the nucleus[16]. Another candidate for the $Ins(1,4,5)P_3$-sensitive calcium pool, at least in peripheral tissues, is the calciosome, a small membrane vesicle which has some properties characteristic of the sarcoplasmic reticulum of muscle[17]. Calciosomes contain the calcium-binding protein calsequestrin and have calcium pumps with immunological properties resembling those in muscle. It is still not clear how calciosomes are related to the $Ins(1,4,5)P_3$-sensitive or -insensitive stores.

Stereochemistry and abbreviations of inositol phosphates

There has been much confusion in the literature concerning the nomenclature of the family of inositol phosphates. Strict adherence to the original IUPAC rules has added further confusion in that addition or removal of a phosphate could necessitate a switch between D- and L-systems of numbering. *myo*-Inositol, represented here in its chair conformation, has a plane of symmetry running through carbon atoms 2 and 5 thus dividing the molecule into chiral halves[8]. Agranoff's turtle is a useful mnemonic for remembering inositol phosphate numbering[9]. Substitution on carbon atoms 1,3,4 or 6 will alter this symmetry and the product must now be designated as D or L to define its position as illustrated for the D- and L-*myo*-inositol 1-phosphate enantiomers (which both occur naturally, see Fig. 1).

A new convention, recently published by the IUPAC, suggests that all inositol phosphates may be numbered as the D-*myo*-inositol derivative (abbreviated as Ins). Using this convention, the L-*myo*-inositol 1-phosphate (shown above) would adopt the numbers of the D-configuration and becomes D-*myo*-inositol 3-phosphate, abbreviated to Ins(3)*P*. The following are abbreviations for some of the more common inositol lipids and inositol polyphosphates appearing in the text.

Ins(4)P	D-*myo*-inositol 4-monophosphate
$Ins(1,4)P_2$	D-*myo*-inositol 1,4-bisphosphate
$Ins(1,4,5)P_3$	D-*myo*-inositol 1,4,5-trisphosphate
$Ins(1\,2cyc,4,5)P_3$	D-*myo*-inositol (1,2-cyclic,4,5)-trisphosphate
$Ins(1,3,4,5)P_4$	D-*myo*-inositol 1,3,4,5-tetrakisphosphate
$InsP_5$	Inositol pentakisphosphate (unspecified isomer)
$InsP_6$	Inositol hexakisphosphate (phytic acid)
PtdIns	Phosphatidylinositol
PtdIns(4)P	Phosphatidylinositol 4-phosphate
$PtdIns(4,5)P_2$	Phosphatidylinositol 4,5-bisphosphate

Another question concerns whether or not the Ins(1,4,5)P_3-insensitive pool can contribute to calcium signals initiated by Ins(1,4,5)P_3. Studies on permeabilized cells and cell fractions have shown that GTP can release Ca^{2+} from both pools independently of Ins(1,4,5)P_3 (ref. 18) and that this release can be blocked by treatments that have no effect on the Ins(1,4,5)P_3-sensitive system. These properties closely resemble the GTP-dependent control of vesicular protein transport through the Golgi[19] and, with the relatively constant levels of GTP in cells, the physiological significance of GTP-induced calcium release in intact cells is doubtful. It has been suggested, however, that GTP may somehow enlarge the Ins(1,4,5)P_3-sensitive pool at

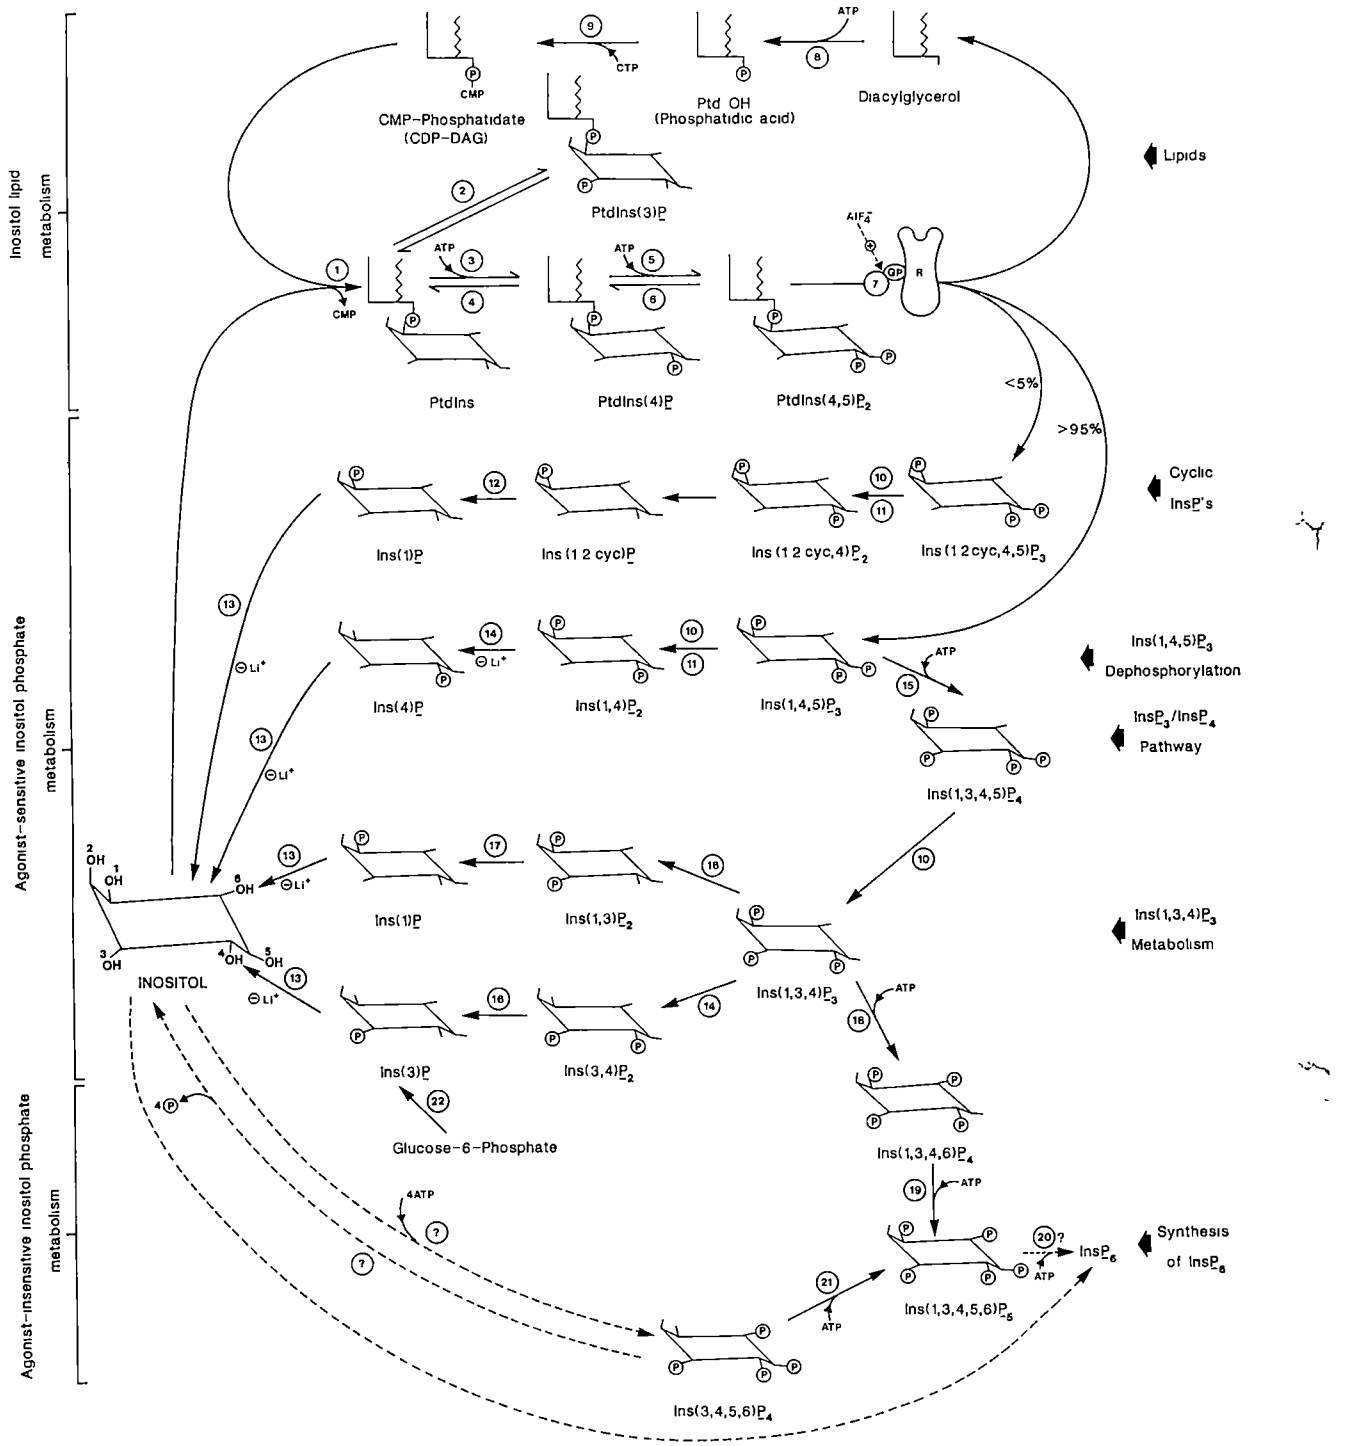


FIG. 1 Summary of known (solid arrows) and suspected (dashed arrows) routes of metabolism of compounds containing inositol and phosphate. To avoid further complexity, the phosphatidylinositol glycans are not illustrated. *myo*-Inositol is represented in its chair configuration and all the inositol phosphates are numbered in the D-isomer configuration (see panel on previous page). The enzymes are 1, PtdIns synthetase (CMP-PA, inositol phosphatidyltransferase), 2, PtdIns-3-kinase (type I); 3, PtdIns-4-kinase (type II), 4, PtdIns(4)P phosphomonoesterase; 5, PtdIns(4)P-5-kinase, 6, PtdIns(4,5)P_2 phosphomonoesterase, 7, phosphoinositidase C, 8, diacylglycerol kinase; 9, CMP-PA synthetase, 10, Ins(1,4,5)P_3/Ins(1,3,4,5)P_4-5-phosphatase, 11, Ins(1,4,5)P_3-5-phosphatase; 12, Ins(1 2cyc)P phosphodiesterase, 13, InsP phosphatase, 14, inositolpolyphosphate-1-phosphatase, 15, Ins(1,4,5)P_3-3-kinase; 16, inositolpolyphosphate-4-phosphatase; 17, Ins(1,3)P_2-3-phosphatase, 18, Ins(1,3,4)P_3-6-kinase; 19, Ins(1,3,4,6)P_4-5-kinase; 20, Ins(1,3,4,5,6)P_5-2-kinase (probably does not exist, as Ins(1,3,4,5,6)P_5 is unlikely to be the precursor of InsP_6); 21, Ins(3,4,5,6)P_4-1-kinase, 22, Ins(3)P-synthetase

the expense of the Ins(1,4,5)P_3-insensitive pool[20] and this process may be controlled by Ins(1,3,4,5)P_4 (ref. 11). The Ins(1,4,5)P_3-insensitive pool may also help to amplify and propagate the calcium signal derived from the Ins(1,4,5)P_3-sensitive store by a mechanism of calcium-induced calcium release (see below).

Ins(1,4,5)P_3-induced calcium mobilization

To release calcium, Ins(1,4,5)P_3 must bind to receptors that are somehow linked to calcium channels connected with the Ins(1,4,5)P_3-sensitive calcium pool. A variety of tissues have a high-affinity stereospecific binding site for Ins(1,4,5)P_3, which recognizes D-Ins(1,4,5)P_3 much better than L-Ins(1,4,5)P_3 (refs 21, 22). This may be the receptor responsible for releasing calcium, because both processes have a similar profile of responses to InsP_3 derivatives and enantiomers[3,21,23]. Heparin also inhibits both the binding of Ins(1,4,5)P_3 to its purified receptor[15] and the mobilization of calcium from liver cells[24].

Individual Ins(1,4,5)P_3-sensitive calcium channels (sensitive to heparin) with conductances of ~10 pico-Siemens (pS) have been recorded from membrane vesicles isolated from the sarcoplasmic reticulum of aortic smooth muscle, which have been incorporated into planar lipid bilayers[25]. The action of Ins(1,4,5)P_3 seems highly cooperative, suggesting that three molecules are required to open the calcium channel[26]. Using a caged molecule from which free Ins(1,4,5)P_3 can be released by a flash of laser light[27], a distinct threshold can be demonstrated above which the response seems to be all-or-nothing[28]; paired light flashes produced facilitation[28]. Overall, this cooperativity may help to explain the long latencies that exist when cells are stimulated with calcium-mobilizing agents[29]. Finally, reconstitution experiments with the purified receptor suggest that the Ins(1,4,5)P_3-binding site, and the Ca^{2+} channel which it controls, may reside in the same protein (C. D. Ferris, R. L. Huganir, S. Supattapone and S. H. Snyder, personal communication).

The Ins(1,4,5)P_3-induced release of calcium can be modulated by a variety of physiological and pharmacological agents. Classical calcium-channel blockers have no effect[30,31], but release is inhibited by cinnarizine and flunarizine[30] and by the potassium channel blocker tetraethylammonium (TEA)[31]. In the absence of potassium, Ins(1,4,5)P_3 is incapable of releasing calcium but other monovalent cations ($Na^+ \gg Tris^+ > Li^+$) can replace potassium, which functions to neutralize the charge developed by the efflux of calcium[32]. In cerebellar membranes, both the binding of Ins(1,4,5)P_3 to its receptor and its calcium-mobilizing action are sensitive to calcium[15,33]. This effect seems to depend on a calcium-mediator protein (calmedin) which is particularly abundant in brain but sparse in peripheral tissues[34]. Also, the Ins(1,4,5)P_3 receptor isolated from brain can be phosphorylated by cyclic AMP-dependent protein kinase, resulting in a decrease in its calcium-mobilizing activity[35].

A characteristic feature of the Ins(1,4,5)P_3 receptor is that it does not desensitize. Any decline in the release of calcium can usually be attributed either to the rapid metabolism of Ins(1,4,5)P_3 (ref. 23) or to the transfer of the mobilized calcium to an Ins(1,4,5)P_3-insensitive pool. A useful analogue for studying calcium mobilization is inositol 1,4,5-trisphosphorothioate which is resistant to metabolism by either the Ins(1,4,5)P_3-5-phosphatase (ref. 36) or the Ins(1,4,5)P_3-3-kinase (ref. 37) and the lack of desensitization of the Ins(1,4,5)P_3 receptor is emphasized by the fact that calcium mobilized by this phosphorothioate derivative is not re-sequestered[37].

Calcium entry—two inositol phosphates involved?

In addition to mobilizing internal calcium through Ins(1,4,5)P_3, many agonists can also promote an influx of external calcium. The three main types of calcium channel used to regulate calcium influx are voltage-operated calcium channels, and two agonist-dependent types which are opened either directly through a receptor (receptor-operated channel) or indirectly through some internal diffusible messenger (second messenger-operated channel)[38]. These calcium channels differ in the way they are activated and, probably, in the very different calcium signals that they generate. Voltage-operated calcium channels, which are usually found in excitable cells, give rapid but brief calcium pulses when activated by membrane depolarization. Opening of receptor-operated channels, however, results in a rapid and maintained elevation in intracellular calcium which is also totally dependent on external calcium. The calcium signal derived from the opening of voltage-operated channels may be amplified by the mobilization of intracellular calcium through a calcium-dependent formation of Ins(1,4,5)P_3 (ref. 39).

There is considerable uncertainty concerning the mechanism and control of second messenger-operated channels. The amount of calcium flowing through these channels is very small, and they do not display the characteristics of typical channels but seem instead to generate a smooth inward current[40]. When cells are stimulated with agonists operating through these channels, the large initial increase in calcium (due mainly to mobilization of internal calcium) is not maintained and the

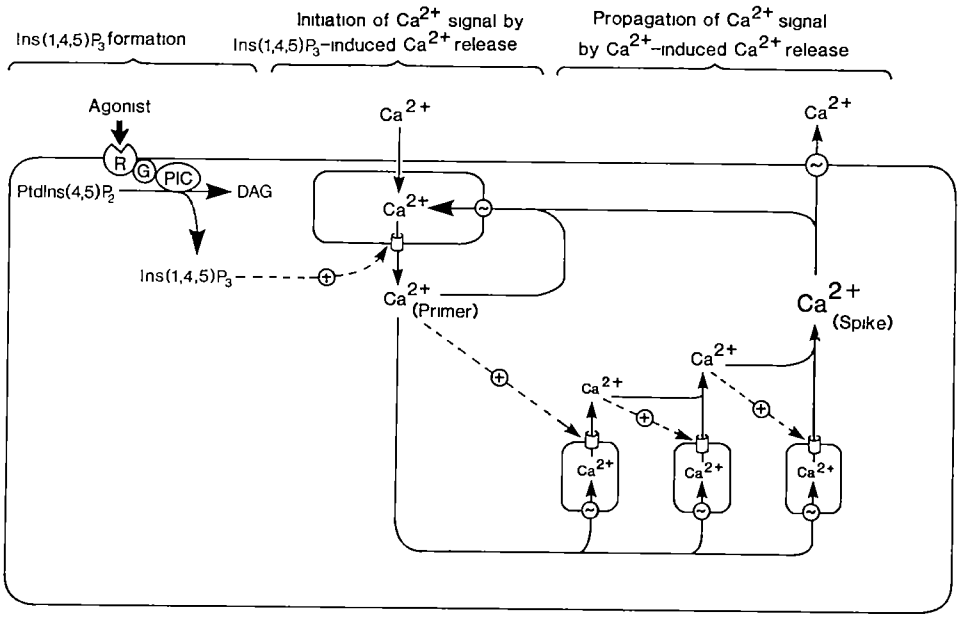

FIG 2 A unified hypothesis of the spatio-temporal aspects of calcium signalling, based on ideas concerning calcium oscillations[67,79] and the propagation of calcium waves[57-60]. A typical response begins with agonists generating Ins(1,4,5)P_3, which then mobilizes calcium from an Ins(1,4,5)P_3-sensitive calcium store and also promotes the entry of external calcium (see Fig 3 for details) to give an initial calcium signal. In some cells, this Ins(1,4,5)P_3-induced calcium signal can act as a 'primer' to drive a process of calcium-induced calcium release from the Ins(1,4,5)P_3-insensitive pools to produce a spike which might be organized in the form of a wave, so spreading the signal throughout the cell.

concentration usually declines to a low plateau level. Both $Ins(1,4,5)P_3$ and $Ins(1,3,4,5)P_4$ have been implicated in controlling this slow entry of external calcium. Just how these inositol phosphates may function is confused because the route of calcium entry is unknown. The simplest hypothesis is that calcium flows directly into the cytosol through channels in the plasma membrane (Fig. 3*a*). Such channels could be regulated by $Ins(1,4,5)P_3$ as has been reported in lymphocytes[41] and mast cells[40]. An alternative capacitative mechanism is that calcium flows first into the ER before entering the cytosol[42]. This is an autoregulatory mechanism because the calcium content of ER that is closely apposed to the plasma membrane somehow regulates the flow of calcium into the cell (Fig. 3*b*). Just how calcium traverses both the plasma membrane and the ER membrane is not known but one idea is that it passes through a pore (analogous to a gap junction) linking the two membranes[43]. Consistent with this hypothesis that the emptying of an internal pool is a prerequisite for entry, is the observation that release of calcium from the internal pool of endothelial cells can precede the entry of external calcium[44]; the control of calcium entry would, therefore, be regulated indirectly by the ability of $Ins(1,4,5)P_3$ to discharge the ER of its calcium (Fig. 3*b*).

This proposed role of the ER may help to explain a possible involvement of $Ins(1,3,4,5)P_4$ in regulating calcium entry, because the action of this inositol phosphate seems to require the simultaneous presence of $Ins(1,4,5)P_3$ (refs. 11, 45). $Ins(1,3,4,5)P_4$, at low concentrations and with a high degree of chemical specificity, increases intracellular calcium concentrations provided that a calcium-mobilizing $InsP_3$ is present[45–47]. This is not the result of $Ins(1,3,4,5)P_4$ competing for the phosphatase that it shares with $Ins(1,4,5)P_3$ which would protect the latter compound[47]. At least some, but not all, of the calcium released comes from outside the cell[47] and the current best guess is that $Ins(1,3,4,5)P_4$ controls the transfer of calcium between intracellular pools[11] (Fig. 3*c*). If some of these pools regulate calcium entry through the capacitative mechanism described above, then this may explain the absolute dependency of calcium entry on $Ins(1,3,4,5)P_4$ (ref 47) (see Fig. 3*c*). The lack of such a dependency on $Ins(1,3,4,5)P_4$ in other experiments[40] may be explained by the slow reversibility of the effects of $Ins(1,3,4,5)P_4$ once they are initiated[48]. Even if $Ins(1,3,4,5)P_4$ is essential for inositol phosphate-controlled calcium entry, its contribution to intracellular calcium mobilization is, as yet, unknown. Finally, we should note that the idea of $Ins(1,3,4,5)P_4$ linking pools, may also provide an explanation for the increased sequestration of calcium caused by this inositol phosphate in a permeabilized cell preparation[49].

Clearly, there is still a lot to learn about how second messengers regulate calcium entry to maintain the signalling system during prolonged periods of stimulation. The relatively small influx of calcium through second messenger-operated channels does not normally result in marked elevation of intracellular calcium, but it does drive calcium oscillations in many cells by providing a steady input of calcium which is then periodically released to give large but transient calcium spikes (see below).

TABLE 1 Calcium wave propagation velocities

Cell type	Temperature (°C)	Propagation velocity ($\mu m\ s^{-1}$)	Reference number

Spatial organization and calcium waves

With the advent of calcium-sensitive indicators and image analysis it has become possible to study how calcium signals are distributed in space and time within a single cell[50]. Calcium signals may either be uniform, or they can initiate in discrete regions from which they may propagate in the form of waves. In bovine adrenal cells, for example, the opening of voltage-operated channels gives a uniform calcium signal, whereas the activation of muscarinic receptors results in a highly localized rise in calcium[51] (Fig. 4) Such discrete initiation sites have been observed in other cells responding to stimuli which hydrolyse inositol lipids, for example, in eggs[52], adrenal glomerulosa cells[53], *Limulus* photoreceptors[54] and NIH-3T3 cells[55]. This spatial organization of calcium signals may be determined by an unequal distribution either of the receptor mechanisms responsible for generating $Ins(1,4,5)P_3$ or of the $Ins(1,4,5)P_3$-sensitive calcium pools[56]. Fertilization is an example where the external signal dictates the initiation site of the calcium signal; this begins at the point of sperm–egg fusion from where it spreads as a propagated wave towards the opposite pole[52,57]. Calcium waves also occur in cardiac muscle[58], myocytes[59,60], gonadotropes[61], endothelial cells[62] and hepatocytes[63]. In all these cells, the waves propagate in a non-decremental way at very similar velocities (Table 1), suggesting a common mechanism, which could be a well-ordered system of calcium pools aligned to allow calcium to spread from one pool to another (Fig. 2). In myocytes, the sarcomeric organization of the myofibrils separates the sarcoplasmic reticulum into regular arrays. *Xenopus* eggs also have a regularly spaced arrangement of the ER lined up close to the plasma membrane[64]. The higher density of ER in the animal as compared with the vegetal hemisphere, may explain how the wave propagates faster in the former[64].

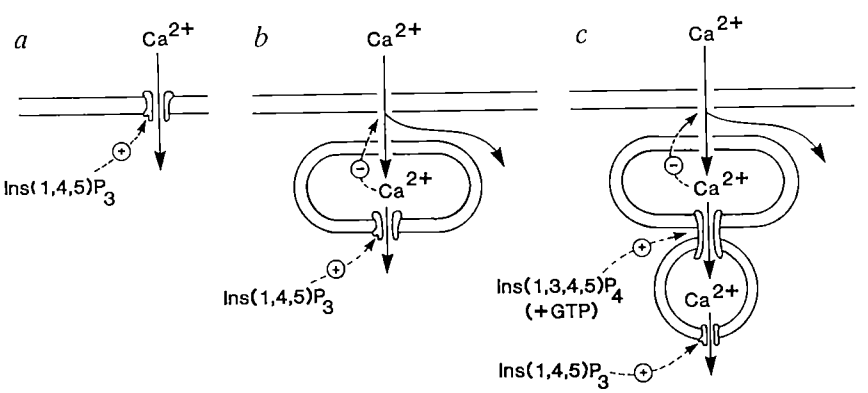

FIG 3 Summary of the proposed mechanisms by which inositol phosphates control calcium entry into cells. *a*, $Ins(1,4,5)P_3$ controls a calcium channel in the plasma membrane[40,41]; *b*, a capacitative model, in which $Ins(1,4,5)P_3$ controls a channel in an endomembraneous compartment which indirectly regulates calcium entry across the plasma membrane through the operation of a negative-feedback loop[42]; *c*, extension of Putney's capacitative model to include a role for $Ins(1,3,4,5)P_4$ in controlling the transfer of calcium between pools[11,45]

There are two principal models of how calcium waves might spread through cells. One suggestion is that $Ins(1,4,5)P_3$ and calcium act as positive regulators of each other[65]. An essential feature of this model is that calcium activates the production of $Ins(1,4,5)P_3$. Although an increase in calcium is not obligatory for the activation of phosphoinositidase C, elevating calcium can enhance the formation of $Ins(1,4,5)P_3$ in certain cells[39]. The other model, to us more attractive, is that the wave spreads by a process of calcium-induced calcium release coupled by diffusion as has been suggested for eggs[52,57,66] and for contractile cells[58,59]. Calcium elevated at a discrete initiation site diffuses to an adjacent store to stimulate the release of calcium and so on down the array[58,59] (Fig. 2). Under circumstances where there are multiple initiation sites, separate waves may result, and these can collide and annihilate each other[59]. This indicates that there is a refractory period following the wave[59], which probably depends on the time required to recharge the calcium stores to the point at which they can once again respond to a calcium signal. We argue below that $Ins(1,4,5)P_3$ may play a key role in priming these stores.

Calcium oscillations

The intracellular level of calcium often oscillates, especially when the phosphoinositide pathway is being stimulated[29,67]. There are many oscillatory patterns, but usually they have the form of a constant baseline which is periodically interrupted by calcium spikes. In contrast to the more classical membrane oscillators which operate through a phasic opening of voltage-operated calcium channels in the plasma membrane, the oscillatory mechanism we are considering here is based on the periodic release of internal calcium (cytosolic oscillators). Most oscillations have a period of between 5 and 60 s (ref. 29) but it is particularly noteworthy that this frequency depends on agonist concentration in some tissues[68–71] but not others[72,73]. Whereas the form and frequency of the oscillations vary from cell to cell, they are remarkably constant for individual cells responding to repeated application of a specific agonist, and have, therefore, been referred to as 'fingerprints'[71]. Some oscillations cease almost immediately when external calcium is removed[70] whereas others persist for a considerable time[67]. All these differences suggest that oscillations may be generated by different mechanisms under different circumstances[29]. In most of the models developed so far, $Ins(1,4,5)P_3$ is a key regulator of the periodic release of internal calcium; however, there is considerable controversy over whether the concentration of $Ins(1,4,5)P_3$ oscillates[67].

In receptor-controlled oscillator models, feedback loops that control the hydrolysis of $PtdIns(4,5)P_2$ by phosphoinositidase C are invoked, that cause the concentration of $Ins(1,4,5)P_3$ to oscillate. This may be through a negative feedback loop using the DAG/protein kinase C pathway[29,74], or calcium may be a positive regulator of $Ins(1,4,5)P_3$ formation[75]. In the latter hypothesis, an important consideration is the strong cooperative interaction between $Ins(1,4,5)P_3$ and the receptor through which it mobilizes calcium[26]. A third model[45,73] invokes the calcium-dependent conversion of $Ins(1,4,5)P_3$ to $Ins(1,3,4,5)P_4$ (ref. 76), which may act as a feed-forward signal to promote further calcium mobilization (see above). An attractive feature of this model is that the calcium spike will not be maintained because full activation of the $Ins(1,4,5)P_3$-3-kinase would soon exhaust all the $Ins(1,4,5)P_3$ and terminate further release because $Ins(1,3,4,5)P_4$ cannot mobilize calcium on its own. However, the surge in $Ins(1,3,4,5)P_4$ may set the stage for the next transient by helping to load the $Ins(1,4,5)P_3$-sensitive pool both by stimulating the re-uptake of calcium into this pool[49] and by promoting the transfer of calcium between intracellular pools[11,45].

Present techniques are not sensitive enough to determine whether $Ins(1,4,5)P_3$ is oscillating in single cells. As oscillations can be observed when a variety of cells are injected or perfused with $Ins(1,4,5)P_3$, receptor-controlled models seem unlikely, at least in these systems[67,77]. In particular, in pancreatic cells, identical oscillations to those produced by acetylcholine were induced by perfusing the cell with the non-metabolizable phosphorothioate derivative of $Ins(1,4,5)P_3$, thus making less likely a role for fluctuations in $Ins(1,4,5)P_3$ or $Ins(1,3,4,5)P_4$ (ref. 77).

Second-messenger controlled models propose that the oscillator resides within the ER/SR system which releases calcium periodically in response to a steady level of $Ins(1,4,5)P_3$. One proposal[33,71,72,78] is that release may become periodic because a negative calcium feedback is known to inhibit both the binding and the calcium-mobilizing action of $Ins(1,4,5)P_3$ (refs 15, 33). Another model, based on that discussed above for the initiation and propagation of a calcium wave in *Xenopus* eggs[57], considers that oscillations arise through an interplay between different calcium pools (Fig. 2). As the $Ins(1,4,5)P_3$-sensitive pool empties it primes the $Ins(1,4,5)P_3$-insensitive calcium pool which then begins to release calcium in an oscillatory manner through the

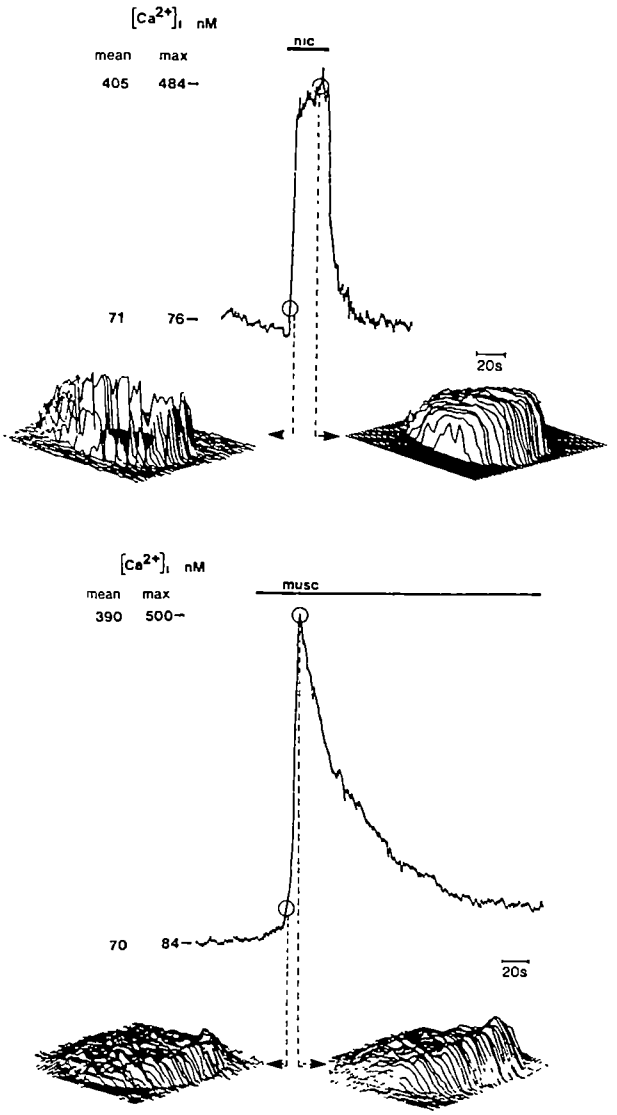

FIG 4 Spatial organization of calcium signalling in a bovine adrenal chromaffin cell during stimulation with either nicotine (nic) or muscarine (musc). Although these two stimuli gave comparable mean and maximal calcium signals, the contour maps reveal that cellular distributions of calcium during the onset (left) and at the peak of the response (right) are very different. During nicotine stimulation, which results in the opening of voltage-operated channels, calcium rises initially around the periphery and then the interior fills in to give a uniform elevation throughout the cell. On the other hand, the increase in calcium following muscarinic stimulation is highly localized, in the form of a crescent, to one region of the cell (Unpublished, using data taken from ref. 51).

process of calcium-induced calcium release[29,67] which has previously been proposed for setting up oscillations in various cell types[56,59,79-81].

Just how calcium release is triggered is uncertain. Whatever the activation mechanism is, it must be related in some way to the filling of the internal store to some constant level to account for the observation that both the rate of rise and the amplitude of the individual calcium spikes remain constant despite the large changes in frequency induced by varying agonist concentrations[69,70,79]. The build-up of calcium in the ER compartment somehow precipitates a sudden release of calcium either because the concentration within the cisternae reaches some critical threshold or because the saturation of the uptake system nullifies its buffering capacity so that cytosolic calcium is elevated, and this provides the activation signal (Fig. 2). The existence of a 'pacemaker' calcium ramp preceding the onset of the calcium spike in endothelial cells supports this latter mechanism[70].

Models based on calcium-induced release are attractive because this process can account for many of the characteristics of calcium oscillations and also for how these can be induced by stimuli other than those which act through inositol lipid hydrolysis. Because oscillations are apparently a calcium-overload response, repetitive calcium spiking will follow any stimulus which increases intracellular calcium, such as potassium depolarization in sympathetic ganglia[80] and smooth muscle[82], or by placing mammalian cardiac muscle in low sodium media or treating it with ouabain[59]. The period between spikes will be determined by how long it takes to charge up (prime) the $Ins(1,4,5)P_3$-insensitive pool. The external concentration of calcium will influence oscillator frequency depending on the extent to which it contributes to the loading of this pool[67]. If the oscillator is reasonably self-contained, that is, most of the calcium in the spike is returned to internal pools, removing external calcium will have little immediate effect. If, on the other hand, most of the calcium is extruded from the cell following each transient, oscillator frequency will be very dependent on external calcium, as it is in myocytes[59], endothelial cells[70] and hepatocytes[79]. The remarkable agonist-specific shapes of individual calcium transients in hepatocytes[74,79] may be explained by agonists having variable effects on the rate of calcium extrusion from cells[79].

Calcium oscillations can be considered as a transformation of the calcium signal into a digital form whose frequency varies with agonist concentration. Calcium signalling may therefore be frequency-coded and the advantages of using frequency instead of amplitude are discussed in detail elsewhere[29,68-70]. Such oscillatory activity may not only mediate the action of neurotransmitters and hormones, but may also be important in regulating cell growth. Prolonged oscillations have been described in lymphocytes responding to antigen[83] and also during interphase of Swiss-3T3 cells, particularly as the cells exit from mitosis[84].

A unifying hypothesis

The distribution of calcium signals in space and time seem to be reflections of a common mechanism, and so we can begin to formulate a unified hypothesis[59,67,79]. Each transient during a calcium oscillation can be spatially organized, as it is often initiated at a discrete site from which it then spreads as a wave throughout the cell. This sequence of events begins with the agonist-stimulated formation of $Ins(1,4,5)P_3$ which activates the process of calcium-induced calcium release that is responsible for the spatially-organized calcium transient as discussed above (Fig. 2). Although the significance of the different components may vary from cell to cell, there is every reason to suppose that both oscillations and signal propagation through calcium waves share a common mechanism.

So far we have concentrated on events in a single cell, but many cells are connected together by means of gap junctions which may allow cells to function in unison with regard to both oscillatory activity and wave propagation. Evidence that a calcium wave may travel from one cell to the next has come from studies of the ciliated tracheal epithelium[85]. Mechanical excitation of one cell accelerates its ciliary beat through an increase in intracellular calcium. A wave of excitation then spreads to neighbouring cells at a rate of ~ 10–$15\ \mu m\ s^{-1}$ (ref. 85). This rate is similar to that for the intracellular waves described earlier (Table 1), so it seems that propagation may spread from one cell to the next, provided that sufficient components of the wave ($Ins(1,4,5)P_3$ or calcium) can flow through the gap junctions. Gap junctions are known to provide an avenue for intercellular stimulation by cyclic AMP (ref. 86) and there is evidence that both $Ins(1,4,5)P_3$ and calcium can flow down a chain of hepatocytes, sometimes in the form of a wave[63]. Intercellular communication of $Ins(1,4,5)P_3$ or calcium may also explain the synchronized calcium oscillations described in endothelial monolayers[87] and the oscillatory release of calcium from the intact liver following hormonal stimulation[88]. It is unclear whether such synchronization arises because all the cells are oscillating in phase, or whether there is a 'pacemaker' centre which entrains neighbouring oscillators by passing information along gap junctions, but either way, the spatiotemporal hypothesis of calcium signalling may help to explain the way in which cell populations communicate with each other to produce synchronous responses.

Why so many inositol phosphates?

Cells contain a bewildering array of inositol phosphates[10-12] which seem to fall into two functional groups (Fig. 1): those whose levels change in response to agonist stimulation and thus have functions related to intracellular signalling, and the agonist-insensitive group concerned with the synthesis of $InsP_5$ and $InsP_6$ whose levels, if they change, do so comparatively slowly during stimulation. In the agonist-sensitive group, the first complication is that, in addition to $Ins(1,4,5)P_3$ being formed by phosphoinositidase C activity on $PtdIns(4,5)P_2$, some cyclic inositol trisphosphate ($Ins(1:2cyc,4,5)P_3$) is also released[89]. $Ins(1:2cyc,4,5)P_3$ is formed very slowly[90,91], but as it is a poor substrate for the phosphatase and kinase that metabolize $Ins(1,4,5)P_3$ (refs 11, 12), it can eventually accumulate to reach a concentration similar to that of $Ins(1,4,5)P_3$, after prolonged stimulation[90]. Although $Ins(1:2cyc,4,5)P_3$ can mobilize calcium[89], its potency is probably at least an order of magnitude less than $Ins(1,4,5)P_3$ (ref. 92). The available evidence, therefore, indicates that cells cannot avoid making cyclic inositol phosphates (because of the way phosphoinositidase C works) but that they are unlikely to use them for any physiological purpose.

Much of the remaining proliferation of agonist-sensitive inositol phosphates originates from the metabolism of $Ins(1,4,5)P_3$ being through two separate pathways (Fig. 1). It can be sequentially dephosphorylated to free inositol (enzymes 10 and 11, Fig. 1) or it can be phosphorylated to $Ins(1,3,4,5)P_4$ by an $Ins(1,4,5)P_3$-3-kinase (enzyme 15, Fig. 1). The latter is strongly activated in v-*src* transformed cells resulting in a sevenfold elevation in the level of an $InsP_4$ (ref. 93). The hydrolysis of $Ins(1,3,4,5)P_4$ to $Ins(1,3,4)P_3$ is a straightforward reaction, but much of the complexity arises because the latter can be hydrolysed back to inositol by separate routes (Fig. 1). What is the significance of this complexity? At this stage we can offer two extreme viewpoints. The complexity could arise because one or more of the breakdown products themselves have physiological functions. One could argue teleologically that this would be undesirable, because the only route of synthesis of any of these other inositol phosphates is through a known second messenger, $Ins(1,4,5)P_3$, so an increase in another putative second messenger would always have to be associated with a rise in calcium. We think that it is more likely that the complexities are simply an inevitable result of the 3-phosphorylation of $Ins(1,4,5)P_3$ to form $Ins(1,3,4,5)P_4$: if the cells are coping

with the formation of two second messengers—Ins(1,4,5)P_3 and Ins(1,3,4,5)P_4—rather than one, more enzymes will be required to catabolize these, and so a complex pattern of intermediates cannot be avoided[11].

$InsP_5$ and $InsP_6$

The metabolism of $InsP_5$ and $InsP_6$ occurs through pathways which are largely separate from the agonist-sensitive pathways (Fig. 1). The main route by which these compounds are made in animal cells is not yet clear and may involve separate pathways for $InsP_5$ and $InsP_6$. In the case of $InsP_5$, a pathway exists from agonist-sensitive inositol phosphates through the phosphorylation of Ins(1,3,4)P_3 to Ins(1,3,4,6)P_4 and thence to Ins(1,3,4,5,6)P_5 (ref. 96) (Fig. 1). However, the main route of synthesis of this inositol phosphate is probably through Ins(3,4,5,6)P_4, which has long been known to be a constituent in avian erythrocytes along with $InsP_5$ (ref. 95) and which also exists in mammalian cells, together with an active and specific kinase which converts it to $InsP_5$ (ref. 94). WRK-1 cells have very high levels of Ins(3,4,5,6)P_4 which increase slowly following stimulation with vasopressin[97]. But the origin of Ins(3,4,5,6)P_4 is, as yet, unknown; that is, we do not know if it is formed from phosphorylation of inositol or indirectly from Ins(1,4,5)P_3. $InsP_6$ is very likely to be generated by phosphorylation of inositol. $InsP_5$ and $InsP_6$ incorporate radiolabel more slowly than 'receptor-generated' inositol phosphates, but they can eventually incorporate [^{3}H]inositol up to a very high level[98], consistent with their high (millimolar) mass levels in the cell[99] (compare for example the micromolar levels of Ins(1,4,5)P_3 (ref. 100)). The proportion of $InsP_5$ to $InsP_6$ changes markedly when HL60 cells begin to differentiate[101]. The overall picture we have of these compounds is, therefore, one of a high resting level which, at least for Ins(1,3,4,5,6)P_5, can perhaps be changed after prolonged stimulation by synthesis from Ins(1,3,4)P_3.

$InsP_5$ and $InsP_6$ are therefore generally assumed to have a 'housekeeping' function rather than being acute second messengers. Speculations about their function have abounded, but perhaps the most promising for $InsP_6$ centres around its unique anti-oxidant properties[102]. Recently it has been suggested that $InsP_5$ and $InsP_6$ are extracellular signals, neurotransmitters[103] for example, but even if correct, this exciting discovery does not help to clarify their intracellular roles.

Lipid diversity and enzyme heterogeneity

Phosphatidylinositol has a rich diversity of forms and functions within the cell, as do the enzymes associated with its metabolism. Apart from its structural role as part of the lipid bilayer, PtdIns is a precursor of second messengers and is a membrane anchor for a great variety of cell surface proteins[104]. This functional diversity is associated with structural variations of both the inositol head group and the fatty-acid tail regions. For example, the PtdIns used for protein anchoring has a fatty-acid composition rich in myristic acid, whereas that attached to PtdIns(4,5)P_2 is predominantly stearoyl-arachidonyl in composition.

A major function of inositol lipids is the one principally under discussion here, to supply second messengers such as Ins(1,4,5)P_3 and DAG in response to calcium-mobilizing agonists[1–7]. For this function, PtdIns is phosphorylated to PtdIns(4)P and then to PtdIns(4,5)P_2; the latter is the precursor used for signal transduction (Figs 1 and 2). The recent discovery of a new lipid, PtdIns(3)P, has emerged from work being carried out on the function of the proto-oncogene c-*src* (ref. 105). The product of c-*src* in association with the middle T antigen of SV40, acts to phosphorylate (and thus possibly to activate) type I PtdIns kinase, which is distinct from the type II enzyme responsible for forming PtdIns(4)P, not least because it phosphorylates PtdIns on the 3-position to give PtdIns(3)P (Fig. 1). A possible role for type I kinase in cell proliferation[105] has recently received strong support from studies which show that platelet-derived growth factor (PDGF) receptors that are deficient in their ability to associate with this kinase fail to stimulate growth[106]. There is also a report of the transient appearance of a PtdIns containing 4 phosphates (possibly PtdIns(3,4,5)P_3) in stimulated neutrophils[107] and of a possible PtdIns(3,4)P_2 and PtdIns(3,4,5)P_3 in PDGF-stimulated fibroblasts[108]. It is tempting to speculate whether such novel lipids fulfil some of the other proposed functions of PtdIns(4,5)P_2, such as remodelling the cytoskeleton[109,110], without compromising the established function of PtdIns(4,5)P_2 as a precursor for DAG and the inositol polyphosphates.

The protein-anchoring function of PtdIns glycans serves as a mechanism for quickly converting a protein which does not have a predominantly hydrophobic region, into a membrane-bound form. It also provides a means for the rapid release of proteins from membranes by reactions catalysed by phospholipase C, as is observed during the change of the protein coat in trypanosomes[104]. Also, the insulin-sensitive hydrolysis of a glycosylated PtdIns releases an inositol phosphate glycan which might be a second messenger for some of the actions of insulin[104].

The growing diversity of the inositol lipids is more than matched by the number of enzymes now known to be responsible for both the initial production and subsequent metabolism of Ins(1,4,5)P_3 (Fig. 1). This complexity is increased because there are different molecular forms of many of these enzymes, for example Ins(1,4,5)P_3-5-phosphatase[111] (enzymes 10 and 11, Fig. 1) and PtdIns synthetase[112] (enzyme 1, Fig. 1). The recent discovery of a possible function of inositol lipids in the nucleus[113] may itself spawn an entirely new family of enzymes. Indeed, Sylvia *et al.*[114] have reported that Ins(1,4)P_2 or its parent lipid PtdIns(4)P can specifically activate a DNA polymerase.

The molecular basis for this enzyme heterogeneity is being studied by genetic techniques which have already revealed that protein kinase C is a heterogeneous enzyme family, with a distinct, and in some cases very precise, tissue specificity[2]. Phosphoinositidase C also exists in a remarkable number of different forms[115] and at least one of these may have coding regions resembling the tyrosine kinase-related oncogenes. Studies on the *Drosophila NorpA* mutant, which is blind but otherwise normal, illustrate the degree to which this phosphoinositidase C family may be tissue-specific. When Yoshioka and colleagues showed that these flies lack phosphoinositidase C in their eyes and suggested that *NorpA* might be a structural gene for this enzyme[116], the idea was received with some sceptism because it would require a phosphoinositidase C gene specific only for photoreceptors. The recent genetic confirmation that *NorpA* does code for a protein with very close similarities to known phosphoinositidase C enzymes, and the observation that transcripts of the gene were localized to the eye and a small region of the brain, suggests that such tissue specificity might indeed exist[117].

Lithium

When administered to intact organisms, lithium induces subtle alterations in neural activity (for example, in manic-depressive illness and diurnal rhythms) and early development (teratogenesis). Lithium is known to reduce the supply of inositol, the key substrate for the phosphoinositide cascade, by inhibiting some of the enzymes (enzymes 13 and 14, Fig. 1), which hydrolyse the inositol phosphates. The 'inositol depletion hypothesis' may explain the neural and developmental effects of lithium on the basis that it inhibits signal transduction indirectly by slowing down the supply of the precursor lipid required to generate messengers such as Ins(1,4,5)P_3 and DAG (ref. 118). The subtlety of the action of lithium is that it seems to be selective; it ignores those receptors which are operating normally, but 'searches out' and dampens down those which are overactive. This selectivity is enhanced by the inhibitory action of lithium being uncompetitive[119] with the result that its effect is progressively enhanced as the level of substrate increases. It is this selective action against overactive receptors

which is the key feature of the inositol depletion hypothesis. Those hypotheses which attempt to explain how lithium might act through a direct effect on signal-transducing elements (adenylyl cyclase or G proteins) cannot satisfactorily explain why lithium has no acute effect on a variety of cellular responses, nor why it has little or no effect on people not suffering from manic-depressive illness. However, it is not presently clear how the apparent tissue (brain)- and agonist (carbachol)-specific inhibition by lithium of inositol phosphate formation[120], is related to its effects on inositol phosphate phosphatases, nor to the influence of lithium on manic depression.

The teratogenic effect of lithium has been investigated in *Xenopus* where its effect is to respecify the dorsal–ventral axis which is fixed at the time of fertilization. This polarity in the early embryo is based on some positional variable or 'organizer' set up in the form of a gradient along the dorsal–ventral axis. More specifically, Busa[121] has proposed that phosphoinositide-derived messengers such as Ins(1,4,5)P_3 or DAG might be the morphogens responsible for early pattern formation. On the basis of the inositol depletion hypothesis, the action of lithium can be interpreted by supposing that it flattens out a normal gradient of phosphoinositide turnover which is postulated to be high in the ventral pole and low in the dorsal pole. Conversely, UV-irradiation which promotes ventralization may produce a uniformly high level of phosphoinositide turnover.

A gradient of phosphoinositide turnover along the dorsal–ventral axis is entirely consistent with the distribution of junctional permeability in the early embryo. Activation of the phosphoinositide messenger pathway, particularly the DAG protein kinase C branch, is known to decrease the permeability of gap junctions[122]. It is significant, therefore, that transfer of the dye Lucifer Yellow between cells in the ventral region is less than in the dorsal region[123]. If pattern formation depends upon messengers such as Ins(1,4,5)P_3 and calcium, which can diffuse between cells (see above), then this reduction in junctional permeability in the ventral pole may serve to confine these morphogens to this region. Treatment with lithium gives a uniformly high level of dye transfer, whereas UV-irradiation reduces transfer[123] and this is exactly in line with the proposal that these two treatments even out the gradient of phosphoinositide turnover to levels which are either uniformly low (lithium) or high (UV-irradiation).

The hypothesis based on a gradient of phosphoinositide turnover is also consistent with experiments where lithium has been injected into one or other pole[121,124,125]. Dorsalization induced by injecting lithium specifically into the ventral pole can be prevented if the lithium is co-injected with *myo*-inositol (but not *epi*-inositol)[125], an observation that provides strong support for the inositol depletion hypothesis. Furthermore, it suggests that a gradient of phosphoinositide messengers may be pivotal in pattern formation during embryogenesis.

Conclusion

In reviewing our current understanding of the role of Ins(1,4,5)P_3 in regulating physiological functions of cells *in vivo*, we have highlighted many complexities: multiple calcium pools, the interrelationship between calcium mobilization and entry, and several possible mechanisms of generating calcium oscillations and waves. Pervading all these aspects to an, as yet unknown degree is the probable helper function of Ins(1,3,4,5)P_4. These subtleties and complexities suggest a reason why the inositol phosphate signalling system is so widespread in biology. It gives to cells the ability to do so much more than just to raise or lower calcium levels. This in turn provides the means to generate an enormous variety of cellular responses from one essentially straightforward set of signals. For example, a cell may distinguish one receptor from another, even though both are working through inositol phosphates. It may use the same signals to control short-term functions (such as secretion or metabolism) and long-term functions (such as growth), and the interactions between different intracellular signals could be virtually limitless in their variety.

The complicated biochemistry of inositol phosphates illustrates the extraordinary diversity of compounds into which *myo*-inositol can be incorporated. Here we have limited our survey mostly to vertebrates, but many more inositol-containing compounds exist in other organisms, particularly in plants. We know very little about how these many compounds are formed, and we are just beginning to fathom functions for only a few of them. In vertebrates, a main challenge for the future is to reveal the wider implications of the phosphoinositide signalling system in the control of complex biological processes, such as early development and the neural mechanisms which underly behaviour. □

ARTICLES

A 42K outer-membrane protein is a component of the yeast mitochondrial protein import site

Dietmar Vestweber, Josef Brunner*, Alison Baker† & Gottfried Schatz

Biocenter, University of Basel, CH-4056 Basel, Switzerland
* Swiss Federal Institute of Technology (ETH), CH-8092 Zürich, Switzerland

An engineered precursor protein that sticks in the import site of isolated yeast mitochondria can be specifically photo-crosslinked to a mitochondrial outer-membrane protein of relative molecular mass 42,000 (42K). This protein (termed import-site protein 42 or ISP 42) is exposed on the mitochondrial surface; antibodies against it block protein import into mitochondria. ISP 42 is the first identified component of the putative transmembrane machinery that imports proteins into mitochondria.

MITOCHONDRIA take up almost all of their proteins from the cytosol[1]. One of the earliest steps in this process is the interaction of protein precursors with receptor-like proteins on the mitochondrial surface[2,3]; none of these proteins has so far been unambiguously identified, although it has been demonstrated that protein import into isolated yeast mitochondria is inhibited by antibodies or Fab fragments raised against a group of outer membrane proteins[4] of relative molecular mass (M_r) 45K. It has also been reported that a 30K protein of mammalian mitochondria[5] or of chloroplasts[6] interacts with a chemically synthesized targeting peptide specific for the corresponding organelle. There is no direct evidence, however, that any of these polypeptides are components of the protein import machinery.

We report here that a 42K protein (ISP 42) of the yeast mitochondrial outer membrane can be specifically crosslinked to a precursor protein which is stuck in the import sites and that antibodies against ISP inhibit import of precursors into mitochondria. ISP 42 is thus a component of the mitochondrial protein-import system.

The translocation intermediate

The chimaeric precursor[7], used to investigate the import site, consisted of a fusion protein[8] with the C terminus crosslinked to bovine pancreatic trypsin inhibitor (BPTI). The fusion protein contained the presequence of yeast cytochrome oxidase subunit IV (coxIV a mitochondrial inner-membrane protein) —joined to the N terminus of mouse dihydrofolate reductase (DHFR a

† Present address: University of Cambridge, Department of Biochemistry, Cambridge CB2 1QW, UK

cytosolic protein). The DHFR moiety had been modified[7] so that its single cysteine was at the C terminus. This modified coxIV-DHFR fusion protein can be over-expressed in *Escherichia coli*, purified, and covalently linked through its C-terminal cysteine to BPTI using a bifunctional crosslinker. If the resulting chimaeric protein is added to isolated mitochondria, it becomes stuck across both mitochondrial membranes; the DHFR moiety is in the matrix, the presequence is cleaved off by the matrix-localized protease and the BPTI moiety remains outside the mitochondria[7]. Mitochondria that have accumulated more than 40 pmol of this transmembranous intermediate per mg protein, no longer import authentic precursor proteins, indicating that the partly translocated chimaeric precursor remains stuck in the mitochondrial import sites. On subfractionation of the mitochondria, the partly translocated precursor is recovered with a sub-mitochondrial fraction enriched in contact sites between the two mitochondrial membranes[9]. The stuck chimaeric protein is thus a convenient and stable tag for mitochondrial protein-import sites.

To crosslink the stuck precursor to components in its vicinity, we placed a photoreactive group between its two major domains. In the stuck precursor, this group should be ideally situated within the membrane junction. To this end, the trifunctional crosslinker shown in Fig. 1 was synthesized. It contains a maleimide group (allowing coupling to the C-terminal sulphydryl group of the fusion protein), an N-hydroxysulphosuccinimide group (allowing coupling to free amino groups of BPTI), and a photoreactive diazirine group. With this crosslinker, between 30% and 75% of the coxIV-DHFR fusion protein could be coupled to BPTI (see Figs below).

The photo-crosslinked product

When the chimaeric precursor bearing the trifunctional crosslinker was incubated with energized yeast mitochondria, ~40% of the added molecules were partially translocated into the organelles and processed by the matrix protease (Fig. 2, lane 2). After illumination of the mitochondria, 7–9% of the stuck chimaeric protein was converted to a species of apparent molecular mass 94K (Fig. 2, lane 3). This species was not formed if import of the DHFR domain was prevented by uncoupling the mitochondria (Fig. 2, lane 9). The photo-crosslink was thus specific for the cleaved, membrane-spanning precursor.

When mitochondria containing the stuck precursor were treated with 50 $\mu g\ ml^{-1}$ of proteinase K before the photoreaction, generation of the photoreaction product was partly inhibited (Fig. 2, lane 5), suggesting that the protein participating in the crosslink was accessible to externally added protease. This inhibition was not caused by the removal of unprocessed precursor from the mitochondrial surface; when mitochondria were treated with proteinase K concentrations of 25–200 $\mu g\ ml^{-1}$, unprocessed precursor bound to the mitochondria was completely degraded at the lowest protease concentration, whereas the amount of the photoreaction product was significantly decreased only at higher protease concentrations (data not shown). These higher levels of protease, therefore, must have degraded the protein participating in the crosslink, indicating that this protein is exposed on the mitochondrial surface.

As the 94K reaction product was precipitated by affinity-purified anti-BPTI-antibodies, it contained the BPTI moiety

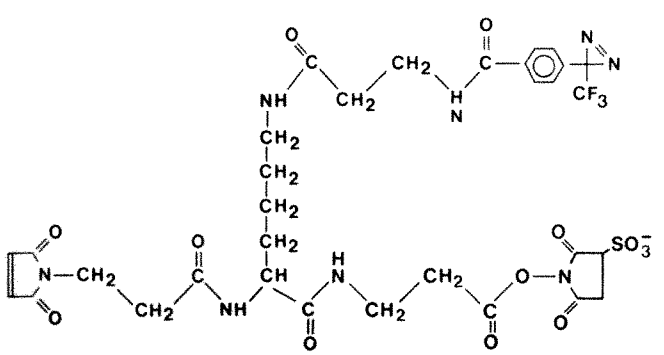

FIG. 1 The trifunctional photoreactive crosslinker. The maleimide- and *N*-hydroxy succinimide groups were used to conjugate BPTI to the precursor protein coxIV DHFR, positioning the photoreactive group between the two proteins.

METHODS. The crosslinker was synthesized by acylation of β-alanine with *N*-BOC-*N*-CBZ-L-lysine-*N*-hydroxysuccinimide ester (Bachem); removal of the *N*-CBZ group, followed by acylation of the free amino group with *N*-[4-[3-(trifluoromethyl)diazirinyl]benzoyl]-β-alanine-*N*-hydroxysuccinimide ester; removal of the *N*-BOC group followed by acylation of the free amino group with 3-maleimido-propanoic acid-*N*-hydroxysuccinimide ester (Fluka); and formation of the active *N*-hydroxy-sulphosuccinimide ester[11].

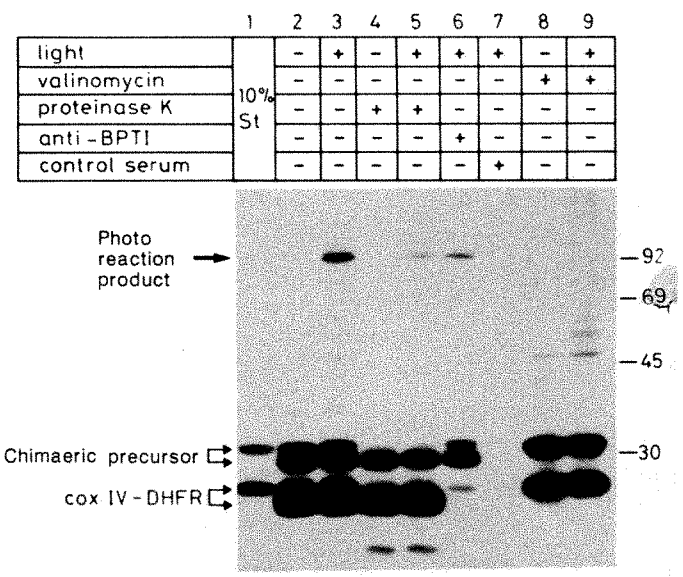

FIG. 2 The transmembrane chimaeric precursor photo-crosslinks to a single protein band. Lane 1, 10% of the amount of chimaeric precursor and residual underivatized coxIV-DHFR that was added to each import reaction. Lane 2, after import into mitochondria. Lane 3, after import followed by illumination of the mitochondria. Lanes 4 and 5, the same as lanes 2 and 3, respectively, except that, after completion of import, mitochondria were teated with 50 $\mu g\ ml^{-1}$ proteinase K for 30 min on ice, followed by addition of phenylmethylsulphonyl fluoride to 0.5 mM. Lanes 6 and 7, after import and illumination, 30 min on ice, followed by addition of phenylmethylsulphonyl fluoride to 0.5 mM. Lanes 6 and 7, after import and illumination, mitochondria were lysed with 0.5% Triton X100 and immuneprecipitated with affinity-purified anti-BPTI IgG (lane 6) or pre-immune IgG (lane 7). Lanes 8 and 9, the same as lanes 2 and 3, respectively, except that mitochondria were de-energized by 10 $\mu g\ ml^{-1}$ valinomycin before import. The positions of relative molecular mass (in K) markers are indicated on the right. Cleaved and uncleaved forms are indicated by arrows on the left for both precursor proteins.

METHODS. The chimaeric precursor was synthesized as described[7], except that the trifunctional crosslinker shown in Fig. 1 was used (dissolved in 20 mM NaPi, pH 7.0) and the incubation time for BPTI with the crosslinker was extended to 45 min at room temperature. Unreacted crosslinker was removed by two successive gel filtration steps. Mitochondria were isolated as described[12]. Import experiments were performed for 15 min at 30 °C with 150 μg (protein basis) of isolated yeast mitochondria in 230 μl import buffer[13] with 40 μl (500 ng; 5×10^5 d.p.m) of the mixture of chimaeric and underivatized precursor. Photoactivation was performed as described[14]. For immunoprecipitations, mitochondria were lysed in 100 μl 50 mM Tris-Cl pH 8.0, 150 mM NaCl, 5 mM EDTA, 0.5% Triton X100. The extract was preincubated with 400 μl of buffer A (50 mM Tris-Cl pH 8.5, 500 mM NaCl, 5 mM EDTA, 0.05% Triton X100, 1 mg ml^{-1} ovalbumin) and 60 μl of fixed *Staphylococcus aureus* cells (Pansorbin, Calbiochem) for 50 min on ice. After pelleting the *S. aureus* cells, the extract was incubated with 100 μg IgG for 2 h at 4 °C and then for 1 h with 110 μl *S. aureus* cells. The cells were pelleted and washed twice with buffer A and once with 20 mM Tris-Cl pH 8.0, 150 mM NaCl. Antigens were released by boiling in SDS-PAGE sample buffer and analysed by SDS-11% PAGE and fluorography of the dried gels.

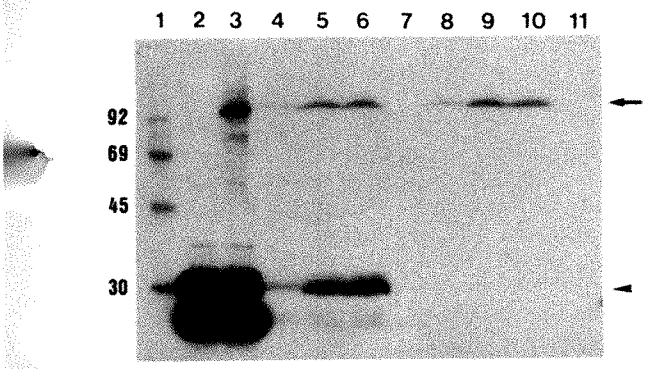

FIG. 3 Antisera against a partially purified 45K outer-membrane protein precipitate the photo-crosslinked product. Lane 1, ^{14}C-labelled molecular mass standards with sizes (K) given on the left; lanes 2 and 3, mitochondria after incubation with a mixture of the chimaeric and the underivatized fusion protein without (lane 2) and with (lane 3) subsequent illumination; lanes 4–11, as lane 3 except that, after illumination, mitochondria were solubilized in 1% Triton X100 (lanes 4–7) or in hot 5% SDS (lanes 8–11); the extracts were then incubated with three different rabbit antisera raised against partially purified 45K outer-membrane protein (lanes 4–6 and 8–10, respectively) or with non-immune serum (lanes 7 and 11). Note that the processed form of the stuck chimaeric precursor (arrowhead) is co-precipitated with the photo-crosslinked product after solubilization with Triton X100, but not after solubilization with hot SDS; by contrast, the photo-crosslinked product (arrow) is precipitated independently of the solubilization method used.
METHODS. Import experiments and immune precipitations from Triton X100 extracts were done as described in Fig. 2. Alternatively, mitochondria (150 μg) were lysed in 50 μl 5% SDS, 50 mM Tris-Cl pH 8.0 for 5 min at 95 °C; the extract was diluted with 1.65 ml of 50 mM Tris-Cl pH 8.0, 150 mM NaCl, 5 mM EDTA and 1% Triton X100. Preadsorption with Pansorbin and immunoprecipitations were performed as in Fig. 2. For each precipitation, 40 μl of rabbit serum and 200 μl of Pansorbin were used. The rabbit antisera had been raised against a partially purified preparation of 45K outer-membrane proteins; purification involved solubilization of the membranes with octylpolyoxyethylene followed by FPLC on MonoQ and MonoP columns (unpublished results).

(Fig. 2, lane 6). Because it was radioactive, it also contained the DHFR moiety (DHFR was the only radioactive moiety of the chimaeric precursor).

Partly translocated precursor

To identify the mitochondrial protein in the crosslinked product, we tested whether this product was immunoprecipitated by antisera against individual outer-membrane proteins. Of several sera tested, only antisera against a partially purified preparation of 45K proteins of the outer membrane immunoprecipitated the crosslinked product (Fig. 3, lanes 4–6 and 8–10). After solubilization of mitochondria with hot sodium dodecyl sulphate, only the photo-crosslinked product was precipitated (lanes 8–10); after solubilization with the non-ionic detergent Triton X100, however, underivatized, processed chimaeric precursor was co-immunoprecipitated with the crosslinked product (lanes 4–6). Association of the stuck precursor with components of the import machinery seems, therefore to survive solubilization with Triton X100 even in the absence of a covalent crosslink.

As shown previously[4], the antisera we raised against 45K outermembrane proteins are not monospecific; if tested by immune blotting against electrophoretically resolved outer membrane, they react with several proteins. Antibodies reacting with each of these proteins were, therefore, removed individually from the serum by preadsorbing aliquots with the corresponding protein band bound to nitrocellulose strips; the preadsorbed aliquots were then retested for their ability to immunoprecipitate the crosslinked product. This ability was abolished only upon removal of antibodies against a 42K protein (data not shown). To verify this result, IgG antibodies which had bound to either the 45K protein band or the 42K protein were eluted from the nitrocellulose strips and tested for their ability to immunoprecipitate either outer-membrane proteins or the crosslinked product (Fig. 4*a*). IgG antibodies affinity-purified on the 45K protein band efficiently precipitated 45K outer-membrane proteins, but failed to recognize the crosslinked product (Fig. 4, lanes 2, 6); IgG antibodies affinity purified against the 42k protein precipitated this protein (as well as some 45K proteins) and also precipitated the crosslinked product (Fig. 4*a*, lanes 3, 7). The residual activity against 45K proteins was not surprising as the 42K band could not be completely separated from the adjacent, much more abundant 45K proteins. Antisera raised against the 45K band can thus be efficiently depleted of anti-42K antibodies, whereas the reverse is not true.

The presence of a 42K outer-membrane protein in the crosslinked product was further documented by the observation that

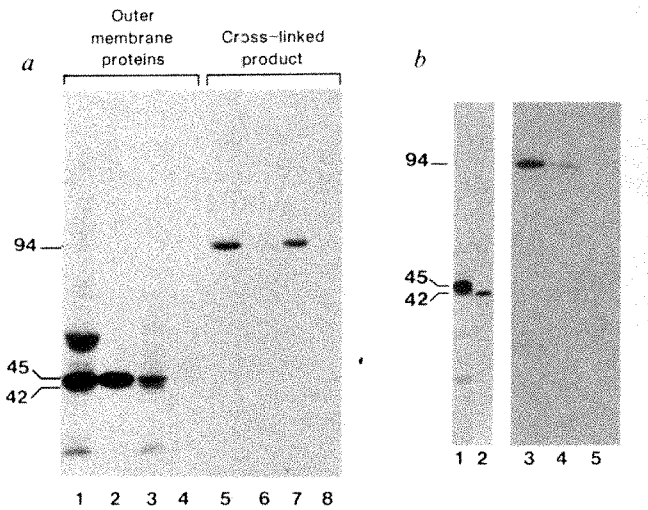

FIG. 4 The crosslinked product is immunoprecipitated by rabbit IgG affinity-purified against ISP 42K protein *a*, or by a monoclonal antibody against ISP 42 *b*. *a*, Lanes 1–4, immunoprecipitation of mitochondria labelled with [^{35}S]methionine *in vivo*; lanes 5–8, immunoprecipitation of unlabelled mitochondria that had accumulated the labelled photo-crosslinked 94K product. Lanes 1 and 5, 50 μg IgG isolated from an antiserum against partly purified 45K protein; lanes 2 and 6, 5 μg IgG affinity-purified against 45K proteins; lanes 3 and 6, 3 μg IgG affinity-purified against ISP 42; lanes 4 and 8, 8 μg IgG isolated from non-immune serum. *b*, Lanes 1 and 2, immunoblot of mitochondrial outer-membrane proteins with: lane 1, IgG from antiserum raised against partially purified 45K outer-membrane proteins; lane 2, anti-ISP 42 monoclonal antibody. Lanes 3–5, mitochondria were allowed to accumulate the photocrosslinked product, solubilized in SDS, and immunoprecipitated with: lane 3, 50 μg IgG against partly purified 45K outer-membrane proteins; lane 4, anti-ISP 42 monoclonal antibody (IgG from 25 ml culture supernatant); lane 5, a mock 'IgG' fraction from 25 ml culture supernatant obtained from a control hybridoma line. Molecular mass sizes (in K) are indicated on the left.
METHODS. Mitochondria were isolated from yeast cells labelled with [^{35}S]methionine as described[15]. Their specific radioactivity was 6×10^7 c.p.m. mg^{-1} protein. IgG antibodies were isolated from total serum by protein A-Sepharose chromatography[16] or eluted from antigens immobilized on nitrocellulose strips with 0.1 M glycine/HCl pH 2.5 (3 min at 4 °C), followed by neutralization to pH 8.0 and protein A-Sepharose chromatography. Import experiments were done as described in Fig. 2 and immunoprecipitations in the presence of SDS were performed as described in Fig. 3 except that for use with the monoclonal antibody Pansorbin was preloaded with rabbit anti-mouse immunoglobulin. The immunoblot experiments shown in *b* were done either with 5 μg of rabbit IgG per lane (followed by decoration with ^{125}I-labelled protein A) or with 1 ml of hybridoma culture supernatant, concentrated three-fold per lane (followed by sequential decoration with 10 μg ml^{-1} rabbit anti-mouse immunoglobulin and ^{125}I-labelled protein A). The monoclonal antibody (IgG$_1$ subclass) was prepared essentially as in 10. *a*, 8% polyacrylamide gel; *b*, 10% polyacrylamide gel. Molecular mass sizes (in K) are indicated on the left margins.

this product was immunoprecipitated by a monoclonal antibody which specifically recognized a 42 K outer-membrane protein (Fig. 4*b*). This antibody had been generated by injecting mice with right-side-out outer-membrane vesicles[10]. Although immunoprecipitation by this monoclonal antibody was not as efficient as that by rabbit antisera, it was specific (compare lanes 4 and 5, Fig. 4*b*). We conclude that the stuck chimaeric precursor is crosslinked to a 42K outer-membrane protein (ISP-42).

Antibodies against ISP 42

Antibodies raised against a major 45K band of outer membrane proteins inhibit protein import into mitochondria[4]. The results mentioned above prompted us to check whether this inhibition was caused by contaminating antibodies against the ISP 42. This was indeed the case. When the antiserum was depleted of IgG antibodies against 45K proteins (Fig. 5*a*) or against 30K or 60K proteins (data not shown), its inhibitory activity on protein import was not significantly decreased; removal of anti-ISP IgG antibodies, however, eliminated the inhibition. Conversely, IgG antibodies affinity-purified on immobilized ISP-42 inhibited mitochondrial protein import, whereas IgG antibodies affinity-purified on immobilized 45K proteins were without effect (Fig. 5*b*). These results suggest strongly that ISP 42 is required for the import of precursor proteins into isolated mitochondria.

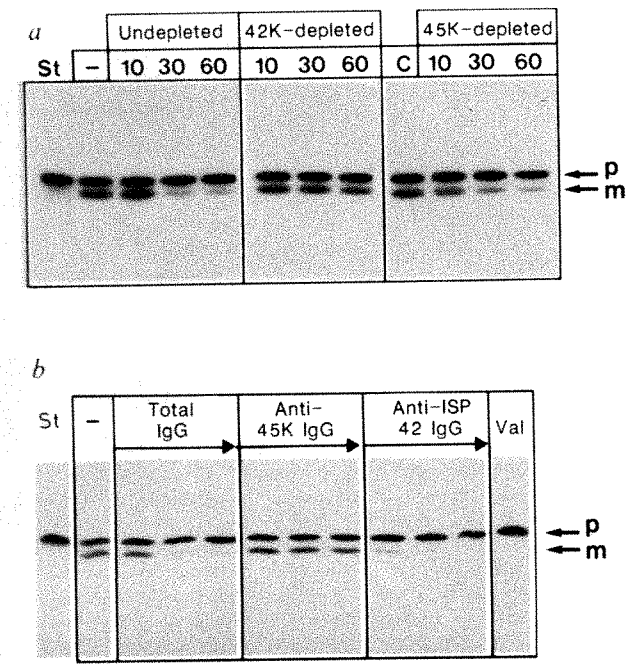

FIG. 5 IgG antibodies against the 42K protein inhibit protein import into isolated yeast motochondria. *a*, Antiserum against partially purified 45K outer-membrane proteins was depleted of antibodies against either 45K proteins or ISP 42 by preadsorption with individual bands of these proteins immobilized on a nitrocellulose strip; IgG antibodies were isolated from these depleted aliquots as well as from an undepleted aliquot by protein A-Sepharose chromatography and tested for their ability to inhibit protein import by isolated yeast mitochondria. *b*, IgG antibodies from the undepleted anti-45K-protein serum as well as IgG affinity-purified from the immobilized bands of 45K outer-membrane proteins or ISP 42 (see above) were tested as in *a*. In *a*, the amount of IgG (in μg) added to each mitochondrial sample is indicated on top of each lane; the lane marked '–' received no IgG. In *b*, these amounts (in μg) were as follows: –, no IgG; Total IgG, 10, 40 and 80; Anti-45K IgG 1, 2 and 3; Anti-ISP 42 IgG 1, 2 and 3. Val, mitochondria de-energized by 10 μg ml^{-1} valinomycin. This negative control establishes that generation of the processed precursor is a valid measure of import. St, 20% of the fusion protein that was added to each mitochondrial sample. p and m, precursor and 'mature' form of the fusion protein.
METHODS. Yeast mitochondria (10 μg protein) were incubated for 45 min at 0 °C without or with the indicated amounts of IgG in 0.6 M sorbitol, 20 mM HEPES-potassium hydroxide pH 7.4, 50 mM glycine, 50 mM Tris (final volume, 40 μl) and tested for import of purified labelled coxIV–DHFR fusion protein (6×10^4 c.p.m.; 12 min at 30 °C). Samples were analysed by SDS-12% PAGE and fluorography.

Conclusions

We show that a 42K protein of yeast mitochondria can be crosslinked to a precursor protein that is stuck in the protein-import machinery. The crosslink seems to reflect a specific association between these two proteins: it occurs with high efficiency and selectivity and only with partly translocated, but not with surface-bound precursor molecules. We conclude that ISP 42 is a component of the mitochondrial protein import site. This is further supported by the finding that IgG antibodies directed against ISP 42 block protein import into mitochondria.

ISP 42 is accessible to protease or IgG antibodies under conditions which preserve the integrity of the outer-membrane barrier. On subfractionation of mitochondria, it cofractionates with outer membranes without being enriched in membrane 'contact sites' (L. Pon and D. Vestweber, unpublished results). ISP 42 is thus exposed on the cytosolic face of the outer membrane.

Its location on the mitochondrial surface suggests that ISP 42 mediates one of the early steps of protein import. It may also be involved, however, in later steps as it is still closely associated with the partly translocated processed precursor.

When yeast mitochondrial outer membranes are fractionated by SDS-PAGE or by column chromatographic methods, ISP 42 is difficult to separate from the major 45K proteins (for example, see Fig. 4*a*, lane 3). As a result, all of our antisera raised against 45K proteins also contain anti-ISP 42 antibodies. This serendipity allowed us to track down the presence of ISP 42 in the crosslinked product. Initially we viewed ISP 42 as a proteolytic

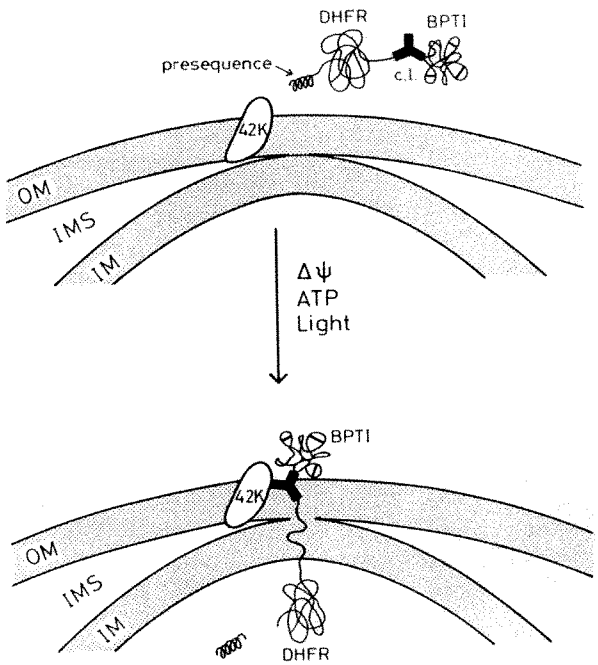

FIG. 6 The photo-crosslinking approach detects ISP 42 in the vicinity of a translocating protein. The coxIV–DHFR fusion protein coupled by a trifunctional crosslinker to BPTI is partly imported by isolated mitochondria in a reaction requring ATP and an electrochemical potential across the inner membrane. The DHFR moiety of the partly translocated precursor is completely transferred into the matrix, the presequence is cleaved off, and the BPTI moiety remains accessible on the mitochondrial surface. The protein thus spans both membranes. Because it blocks protein import into mitochondria, it remains stuck in the protein import machinery[7]. Upon exposure to high-energy light, the photoreactive group in the trifunctional crosslinker covalently links the precursor protein to ISP 42. OM, outer membrane; IM, inner membrane; IMS, intermembrane space.

fragment of one of the 45K proteins[4]. The experiments reported here, however, show clearly that ISP 42 is a distinct protein and that the inhibition of protein import by antisera raised against the 45K protein band[4] is caused by antibodies against ISP 42.

On SDS-polyacrylamide gel electrophoresis, the apparent molecular weight of the crosslinked product (94K) is larger than the sum of the two partners (32K and 42K). As the crosslinked product must have a branched, triskelion-like structure, its aberrant migration in SDS-polyacrylamide gels is explicable.

ISP 42 is probably not the only protein mediating the import of precursor proteins into mitochondria. The 30K polypeptides identified in mammalian mitochondria[5] and chloroplasts[6] may represent an additional component of the import machinery in these two organelles. Characterization of a multi-component system is usually quite rapid once the first component has been identified. The results presented here should thus help in detecting additional proteins of the mitochondrial protein-import system. □

Structure of the guanine-nucleotide-binding domain of the Ha-*ras* oncogene product p21 in the triphosphate conformation

Emil F. Pai, Wolfgang Kabsch, Ute Krengel, Kenneth C. Holmes, Jacob John & Alfred Wittinghofer

Max-Planck-Institut für medizinische Forschung, Abteilung Biophysik, Jahnstrasse 29, 6900 Heidelberg, FRG

The crystal structure of the guanine-nucleotide-binding domain of p21 (amino acids 1–166) complexed to the guanosine triphosphate analogue guanosine-5′-(β, γ-imido)triphosphate (GppNp) has been determined at a resolution of 2.6 Å. The topological order of secondary structure elements is the same as that of the guanine-nucleotide-binding domain of bacterial elongation factor EF-Tu. Many interactions between nucleotide and protein have been identified. The effects of point mutations and the conservation of amino-acid sequence in the guanine-nucleotide-binding proteins are discussed.

GUANINE-nucleotide-binding proteins, such as elongation factors and signal-transducing G proteins, exert their function by cycling between an inactive, GDP-containing and an active, GTP-containing conformation[1–3]. The cycling between these conformations is mediated by exchange factors or hormone-activated receptors which increase the exchange rate of the strongly bound GDP with GTP. The system returns to the ground state by the intrinsic GTPase activity of the protein. The GTPase reaction is usually increased by the effector, which in turn is switched on by the interaction.

The product of the N-, Ki- and Ha-*ras* genes, p21, is a small guanine-nucleotide-binding protein that has been found to be mutated in a large number of human tumours[4]. Its exact cellular role is unknown, although it is believed to be involved in a growth-promoting signal-transduction pathway. As with all other guanine-nucleotide-binding proteins, p21 is active only in the GTP-bound form; only in this form does it interact with GAP (GTPase activating protein) which is either an effector of *ras* action or its negative regulator[5–7]. The interaction between p21 and GAP ensures that p21 is maintained in the GDP bound conformation.

The crystal structure of the p21-GDP complex has recently been described[8]. We were able to crystallize the guanine-nucleotide-binding domain of $p21^{Ha\text{-}ras}$ in the active GTP conformation by using various slowly hydrolysing GTP analogues[9]. We report the three-dimensional structure of the guanosine-5′-(β,γ-imido)-triphosphate (GppNp) complex determined by X-ray crystallography. This should enable us to define the conformational transition between the GDP and the GTP bound states and to investigate in detail the site of interaction of p21 with GAP.

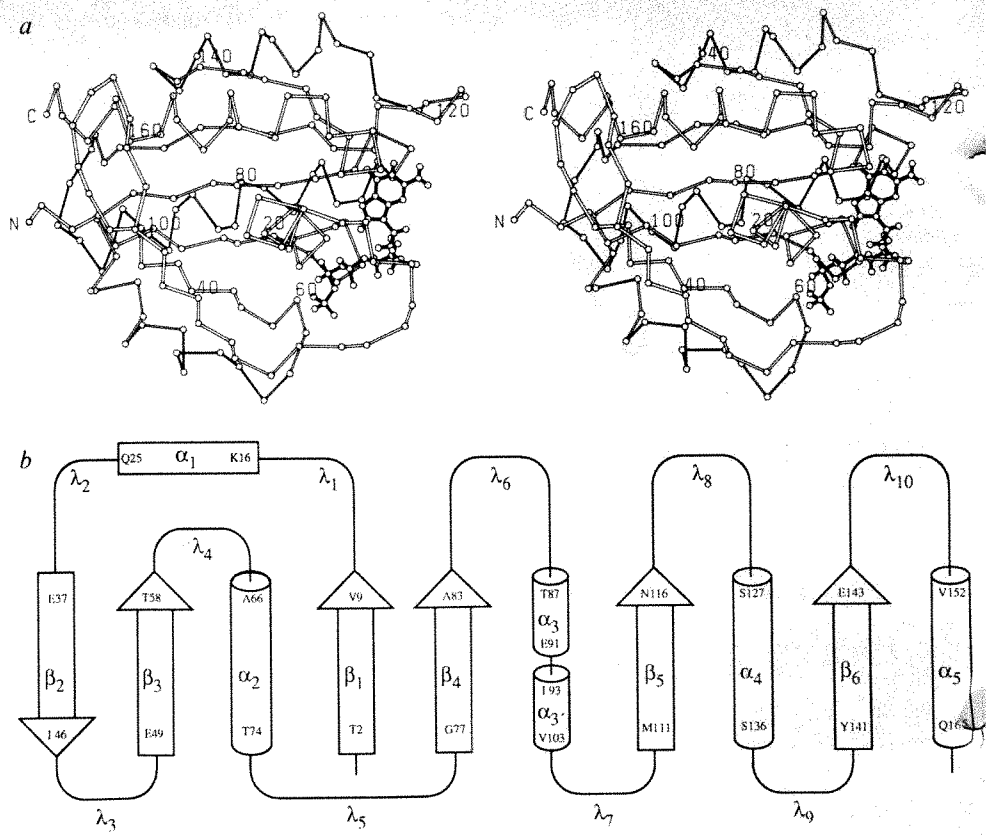
Our chain tracing is different from that reported earlier for the p21-GDP complex. After communicating our findings to Kim and coworkers, they reevaluated their interpretation. Their revised chain tracing, as described in correspondence to *Science*[10], now agrees with that presented here.

Protein preparation and crystallization

Cloning, over-expression and purification of the truncated form $p21_{c'}$ (amino acids 1–166) was performed as described for the native protein[11,12]. C-terminal truncation did not affect nucleotide binding or GTPase activity[13]. Crystals of the complex of $p21_{c'}$ and the slowly hydrolysing analogue GppNp were grown according to Scherer *et al.*[9].

Backbone structure

In the final stages of our model building it became obvious that we would not be able to obtain a good fit between model and observed electron density, when following the chain tracing as reported by DeVos *et al.*[8,14], for the GDP complex. The largest discrepancies arose at Tyr 4 where there was not sufficient density to account for the aromatic ring and in the connecting



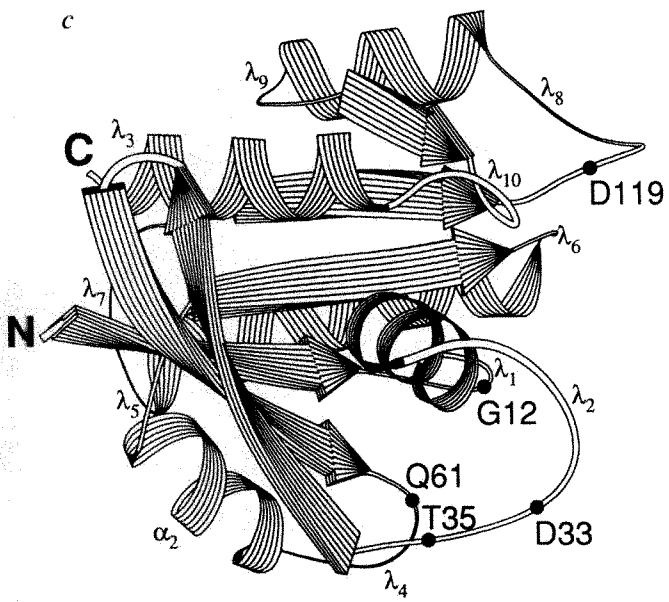


FIG. 1 Structure of the nucleotide-binding domain of human c-Ha-*ras* p21. *a*, C_α-stereo plot. Filled-in bonds show the GppNp molecule. *b*, Topological order of secondary structure. The definition of secondary structure is according to ref. 52. Helices are represented as cylinders and marked α_1–α_5. Helix α_3 is slightly distorted. The six strands of the β-sheet are shown as arrows β_1–β_6. Loops are labelled λ_1–λ_{10}. Amino-acid residues at the beginning and at the end of secondary structure elements are given. *c*, Schematic representation of the three-dimensional structure[53]. All loops and a few important amino-acid residues are labelled for orientation. The helix, which was not found in the structure of p21–GDP (ref. 8) is α_2.

loops, especially in the 'glycine-rich' loop (residues 10–16) where gaps in the electron density had to be crossed. When β-strands 3 and 1 in Fig. 3 of ref. 8 were changed to β_1 and β_3, respectively, and the connecting loops corrected accordingly (Fig. 1*b*, *c*), these problems could be completely resolved. With this chain tracing there is a continuous arrangement of main chain atoms in the electron density. It should be noted that our interpretation is consistent with p21 having the same topology as the GDP-binding domain of EF-Tu, the only other guanine-nucleotide-binding protein with a known three-dimensional structure[15,16]. It also confirms the structural model of p21 (refs 16–18) which was based on the sequence homology between EF-Tu and p21 (ref. 19).

Figure 1*a* shows a C_α stereo plot of the nucleotide-binding domain of the p21 protein together with an atomic structure of GppNp (calculated positions of some hydrogens are added for clarity). The topological arrangement of the secondary structural elements is shown in Fig. 1*b*, including the amino acids at the beginning and end of the corresponding elements. The N terminus is in the third strand of the β-sheet. The 'glycine-rich' loop, λ_1, connects it to a short α-helix that starts with Lys 16 and ends with Gln 25. It is linked to β_2 through loop λ_2 which contains elements important for guanine base and ribose binding (Phe 28, Val 29) and for interaction with GAP (Asp 33, Ile 36, Asp 38, Tyr 40). The second strand, β_2, is connected to the third, β_3, by λ_3, in fact a β-turn. Loop λ_4 contains the region around amino-acid 61 which is mutated in many human tumours. In the triphosphate bound structure this loop is followed by a short three-turn-helix, α_2 in Fig. 1*b*, which was not observed in the GDP bound form of the protein[8]. Loop λ_5 connects helix α_2 and β_4. In addition, the third helix, α_3, which starts with Thr 87 and ends with Val 103, has a kink at Glu 91. The rest of the topology is identical to that which has been reported[8,14]. As mentioned above, this topology including the additional helix α_2 is identical to that found for the GDP-binding domain of EF-Tu from *Escherichia coli*[15,16]. This increases the probability that the overall architecture of all the guanine-nucleotide-binding proteins is very similar and that perhaps the same structural elements are involved in their transition between GDP- and GTP-bound forms.

Figure 1*c* shows the $p21_{c'}$–GppNp structure as a ribbon drawing. All loops and helix α_2 not present in the GDP form[8] are labelled. Loop λ_2 contains the site of interaction with the possible effector molecule GAP (ref. 6). It is highly exposed to the solvent and is probably in a different conformation from that found in the GDP bound structure, as p21 in the GDP bound form only weakly interacts with GAP (ref. 6). The sites of oncogenic activation on loops λ_1 and λ_4, and some selected amino acids, are indicated.

The phosphate binding loop

Many mononucleotide-binding proteins have a stretch of amino acids with the consensus sequence G-X-X-X-X-G-K-S/T

All X-ray diffraction data from the crystals were recorded on an electronic area detector (Siemens/Nicolet, Madison, WI). X-rays (CuK_α) were generated using a GX-18 rotating anode (Elliot/Enraf-Nonius, Delft) and focused by Franks double-mirror optics. The anode was operated as 35 kV and 50 mA. An oscillation camera (Supper, Natick, Mass.) with a vertical rotation axis was used to move the crystal. Camera and detector were controlled by a simplified version of a program by Durbin *et al.*[45] running on a small dedicated computer (PCS, München, FRG). For each data-collection run a sequence of adjacent electronic rotation pictures (data frames) was transferred by Ethernet to a large computer (CONVEX C210) and processed by the program XDS (refs 46, 47). The program terminates with a list of squared structure factor amplitudes corrected for absorption and radiation damage. Only one heavy-atom derivative ($K_2[Hg(CN)_4]$) could be obtained using the soaking technique. Two more derivatives were prepared by co-crystallizing the protein with heavy atoms. Each data set was obtained from one crystal to avoid systematic errors in heavy-atom occupancies for the derivative crystals. Two data sets were collected for a native crystal by changing the orientation of the capillary after the first set. The two sets were processed independently and subsequently scaled together. The symmetry R factor in intensities for all reflections was 5.2%, or 4.1% and 4.3% for the two separate runs, respectively. MMN, CH_3HgNO_3.

* $R_{sym}=\sum_h\sum_i|I_{h,i}-I_h|/\sum_h\sum_i I_{h,i}$ where $I_{h,i}$ are symmetry related intensity observations and I_h is the mean intensity of reflections with unique indices h.

† $R_F=2\sum_h|F_{PH}-F_P|/\sum_h|F_P+F_{PH}|$ where F_{PH} and F_P are the derivative and native structure factor amplitudes, respectively.

(single-letter amino-acid code) which connects a β-strand with an α-helix. This loop usually contains additional glycines or prolines. In p21 the sequence of this element is G_{10}-A-G-G-V-G-K-S_{17} and the mutation of Gly 12 to any other amino acid except proline activates the transforming potential of the protein. This is also true for the replacement of Gly 13 by valine. Figures 2 and 3*a* show the arrangement of the corresponding residues in the triphosphate-bound structure of p21. The three main-chain nitrogens of residues 13 to 16 in the loop and those of residues 17 and 18 in the following α-helix, point towards and are within 3.5 Å of the phosphate oxygens and are thus able to form hydrogen bonds. At the present resolution, the amide nitrogen of residue 16 is closest (3.0 Å) to one of the β-phosphate oxygens. The amide nitrogen of residue 18, which is located in helix α_1 following loop λ_1, forms a hydrogen bond to the pro-R oxygen of the α-phosphate. This is in agreement with our results obtained with α-thiophosphate analogues of GDP and GTP, which show that the replacement of the pro-S oxygen by sulphur is better tolerated than the replacement of the pro-R oxygen[11,20].

Lys 16 stretches across the phosphates. Its amino group is close enough to the γ-phosphate for an ion-pair interaction and forms hydrogen bonds with the main-chain oxygens of residues 10 and 11. It is remarkable that the same structural arrangement of lysine has been reported for the nucleotide-binding loop of porcine adenylate kinase, an ATP-binding protein. Here too, the equivalent lysine residue (Lys 21) makes contact with the main chain at the corresponding positions (Gly 15, Gly 16) (ref. 21). Point mutations in the nucleotide-binding loop of *E. coli* adenylate kinase also have large effects on the kinetics and structure of the enzyme[22], as has been found in p21.

The phosphate-binding loop has sometimes been called the flexible loop because of its high content of glycine residues. In the structure of the triphosphate conformation of p21, this region shows high density with low-temperature factors for all atoms. Taken together with the fact that many main chain nitrogen and oxygen atoms interact not only with the nucleotide, but also with other parts of the structure, this seems to indicate that the loop is very rigid (Fig. 3*a*).

Guanine nucleotide binding site

Details of the interactions between nucleotide and protein are shown in a sketch in Fig. 2. The guanine base is sandwiched between the aromatic side chain of Phe 28 on one side and the aliphatic part of the side chain of Lys 117 on the other. The amino group of Lys 117 is 3.5 Å away from the endocyclic oxygen of the ribose. It is close enough to the main chain carbonyl group of Gly 13 in the phosphate binding loop λ_1 to form a hydrogen bond and thereby connecting loops λ_8 and λ_1. The strong hydrogen bond between O6 of the guanine ring and the amide nitrogen of Ala 146 is also important for the binding of the guanine base. It has been found[23], using an *in situ* colony hybridization assay, that the mutation Thr 144 → Ile reduces the

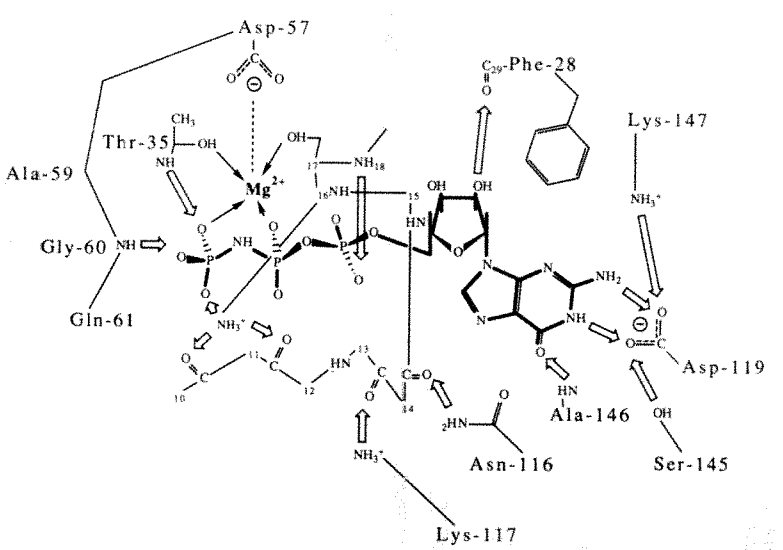

FIG. 2 Schematic drawing of protein–nucleotide interactions. Hydrogen bonds are indicated by open arrows (⇒), bonds between the magnesium ion and its ligands are shown as solid arrows (→). Some important interactions between side-chain atoms are also included.

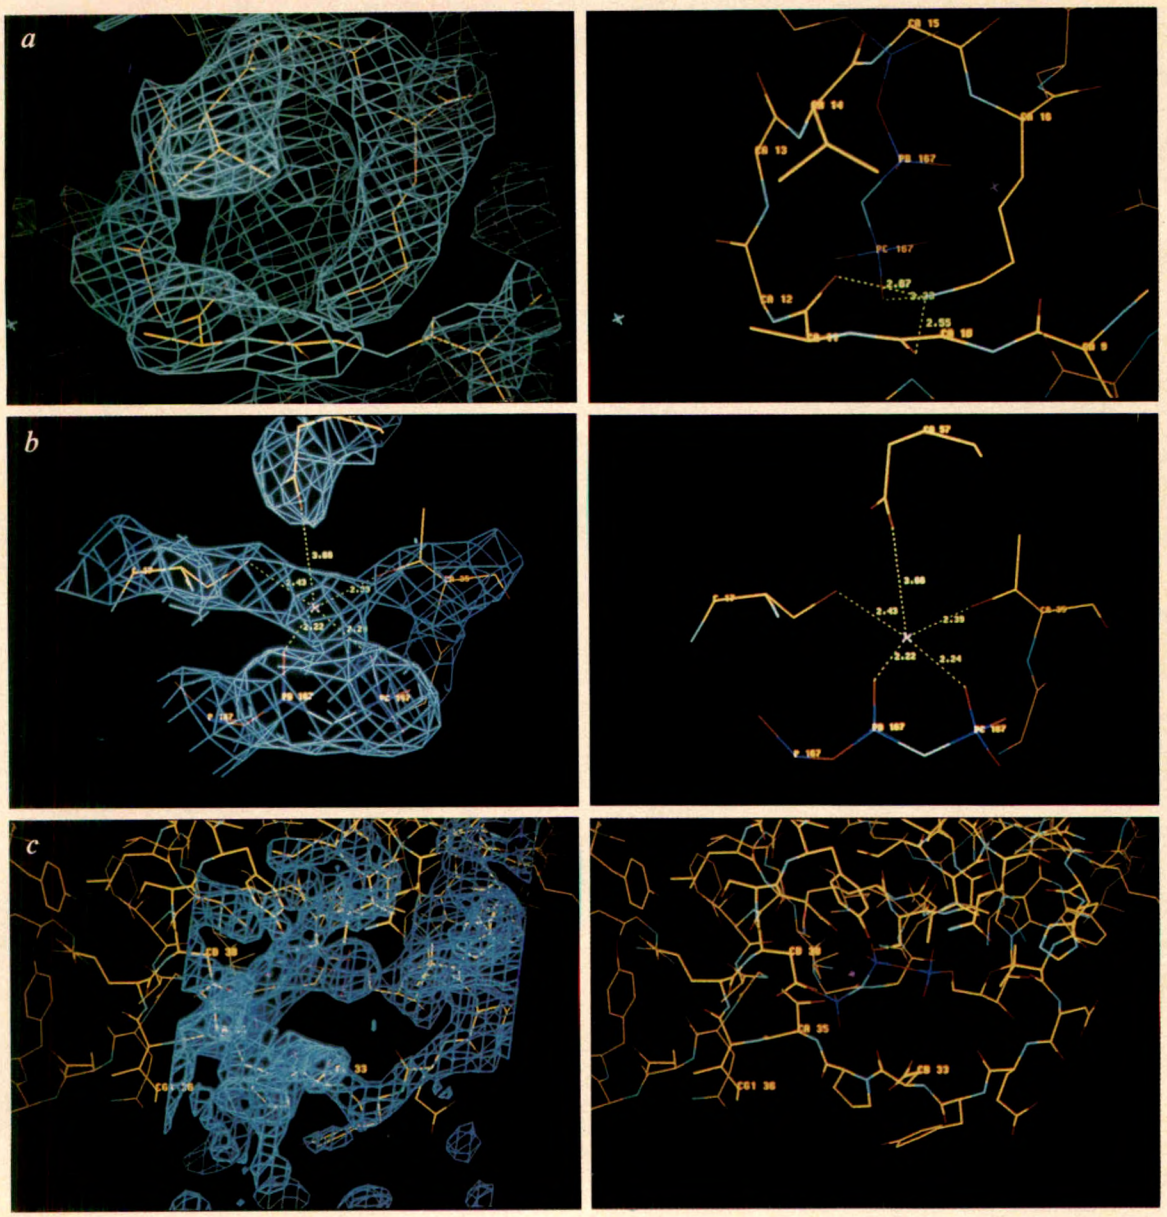

FIG. 3 Part of the 2.6 Å electron density map with the fitted molecular model. *a*, Loop λ_1, the glycine-rich, phosphate-binding loop. All parts of this loop are in well defined density. There are no indications of flexibility. The side chain of Lys 16 folds back towards amino acids 10 and 11. It interacts with their backbone carbonyls and with the γ-phosphate. Electron density is contoured at 20% of maximum density. *b*, Magnesium ion surrounded by its ligands. β- and γ-phosphate, Ser 17 and Thr 35 coordinate in an only slightly distorted planar configuration. Asp 57, which is a little further away, probably interacts with the metal ion via a water molecule. (Contour at 25%.) *c*, Loop λ_2, which interacts with the GTPase activating protein, GAP. This stretch of residues is somewhat detached from the rest of the molecule making it easy for another protein to bind. (Contour at 20%.)

affinity for GDP. Our analysis suggests that this effect is an indirect one, through the local main-chain conformation, possibly weakening or even destroying the interaction of Ala 146 with O6 of GTP. We have also shown that h6-GDP, where the oxygen atom at position 6 of the guanine base has been removed, binds with 25-fold-lower affinity than GDP (Linke, R. *et al.*, unpublished results). Pointing to the importance of this interaction is the fact that a similar result with even lower relative affinity for h6-GDP has been found with EF-Tu (ref. 24).

Asp 119 is part of the N-K-X-D motif which is highly conserved in all guanine-nucleotide-binding proteins and is called the guanine-specificity region. The carboxylate group of Asp 119 contacts the exocyclic 2-amino group and the endocyclic N1 of guanine. This bonding scheme has been observed by NMR for the interaction between guanine- and a glutamic-acid containing dipeptide[25]. Asp 119 is also close enough to interact with the side chain hydroxyl of Ser 145 and with the amino group of Lys 147, both of which again are conserved in the small guanine-nucleotide-binding proteins. It is therefore, not surprising that the mutation of Asp 119 in p21 and of Asp 138 in EF-Tu drastically reduces the affinity for guanine nucleotides[26–30].

The ribose of GppNp is in a 2′-endo conformation. Asp 30 is pointing in its direction but is too far away to make any hydrogen bonds. The main-chain carbonyl atom of residue 29, however, is within hydrogen bonding distance of the 2′-hydroxyl group of the ribose (Fig. 2). The 2′-and 3′-hydroxyl groups are exposed to the solvent, as one would expect, as at least one of the ribose hydroxyl groups of GTP or GDP can be substituted by the rather bulky fluorescent N-methylanthraniloyl group without causing a significant decrease in binding affinity[31].

As in the p21–GDP structure, the phosphate–binding loop is wrapped around the β-phosphate group, with four main-chain

The difference Patterson map for the CH_3HgNO_3 (MMN) derivative clearly revealed a single dominant heavy-atom site All other derivatives were analysed by the difference Fourier technique using the phases derived from the MMN derivative Six strands of β-sheet and four α-helices were identified in the initial MIR electron-density map The loop regions, however, were not easy to interpret and some uncertainties about the correct connections remained Omitting the dubious regions in the map, a polyalanine backbone model was fitted to the electron density using the interactive graphics program FRODO (ref 48) adapted to an IRIS 4GT (Silicon Graphics Inc, Mountain View, Ca) by C M. Cambillau The partial model was refined to an *R*-factor of ~38% using the program PROLSQ (ref. 49) A new map was then calculated combining phase probability distributions from the partial model with the derivative information Model bias was greatly reduced by incorporating the method developed by Read[50] into our program package The new map was of better quality and most of the amino-acid side chains were clearly recognizable The resulting new model was refined with the program XPLOR (ref 51) to an *R*-factor of 33% An additional helix (helix α_2 in Fig. 1*b*) was identified and two strands of β-sheet and three connecting loops were reassigned in the new map Two more rounds of minor rebuilding and refinement were carried out The last refinement was performed with the program PROLSQ and individual atomic temperature factors were determined At this stage the R-factor dropped to 22.9% with all observed data from 10 to 2 8Å resolution included in the refinement

peptide nitrogens in the loop pointing towards the phosphates. Other main-chain amide nitrogens which interact with the phosphates are NH-17, NH-18, and that of Gly 60, located just after the end of β_3 and beginning of loop λ_4. Gly 60 is conserved as part of the D-X-X-G motif in all guanine-nucleotide-binding proteins. Mutation of this residue in the α-chain of the G protein G_s creates a protein with equal affinity for GDP and GTP, which is, however, no longer able to stimulate adenylyl cyclase[32]. Also, the protein can no longer switch between the GDP and the GTP bound state[32]. This points to a structural role for this glycine residue in the guanine-nucleotide-binding proteins. In the structure presented here, the main chain at Gly 60 adopts a sharp bend not possible for any other amino acid.

Magnesium-ion coordination

Numerous studies of elongation factors, G proteins and p21 have shown that Mg^{2+} is essential for proper binding of ligands, for the GTPase activity and for the structural integrity of the proteins. We have shown before that the metal ion in the p21-bound GDP-Mg^{2+} has a monodentate coordination to the β-phosphate[20]. In analogy to EF-Tu and other nucleotide-binding proteins, one would expect that p21 in the GTP complex binds the metal ion as a bidentate β-γ-complex[33]. We have identified an electron density close to the β- and γ-phosphate groups as Mg^{2+}, as excess Mg^{2+} is always present during protein purification and crystallization.

Magnesium ions in nucleotide-binding proteins have six ligands coordinated in an octahedral arrangement. Figures 2 and 3*b* show the coordination of Mg^{2+} in the triphosphate conformation of p21. In addition to the β- and γ-phosphates, we can identify at least two if not three ligands which are close enough to the metal ion to be in the first coordination sphere. These are Ser 17, Thr 35, and possibly Asp 57, all three of which are totally conserved in small guanine-nucleotide-binding proteins and the elongation factors (Palme, K. *et al.*, unpublished results; Chardin, P., unpublished results). Ser 17 and Asp 57 are also conserved in the large G_α proteins. Although Ser 17 and Thr 35 are within bonding distance of the metal ion, Asp 57 points towards the metal ion but is so far away that there is possibly an intermediate water molecule. Figure 2 shows that Thr 35, in addition, interacts through the main-chain amide nitrogen with one of the γ-phosphate oxygens.

Structure of the effector loop

It has been shown previously that the site of interaction of GAP with p21 embraces amino acids 32 to 40. Certain mutations in this region abolish the ability of p21-GTP to be activated by GAP as well as its biological activity in yeast[34–37]. Figure 1*b* shows that only amino acids 32–36 are situated in loop λ_2. The other amino acids that are thought to be involved in GAP interaction are part of the second β-strand, β_2. Figure 3*c* shows the three-dimensional structure of this region. The loop is detached from the otherwise compact structure of the molecule and would thus be easily accessible to other proteins. The residues which have specifically been shown by mutagenesis to be involved in the interaction with GAP are Asp 33, Thr 35, Ile 36, Asp 38 and Tyr 40 (refs 34–37). As described above, Thr 35 coordinates to Mg^{2+} and to the γ-phosphate. The effect of the Thr 35 → Ser or the more severe Thr 35 → Ala mutation on GAP activity therefore seems to be mediated by the manner in which these mutations change metal-ion binding. Figure 3*c* shows that the other residues in this area, believed to be involved in p21-GTP-GAP interaction, are more or less exposed to the solvent. The loop part of the effector region, amino acids 32–36, forms a ridge that sticks out of the rest of the protein. GAP interacts with p21 much more strongly in the GTP bound form than in the GDP bound form[6,37] just as EF-Tu has a 100-fold higher affinity for aminoacyl-tRNA in the GTP complex[38]. It is to be expected, therefore, that the structure of the effector loop is different in the two conformations.

Antibody Y13-259 binding site

The antibody Y13-259 (ref. 39) has been found to be of particular importance because its microinjection into NIH 3T3 cells and certain other fibroblastic cell lines causes reversion of the transformed phenotype induced by oncogenic *ras* mutations. The binding epitope of this antibody has been mapped by deletion cloning[40] and more precisely by site directed mutagenesis[28] to the region of p21 comprising amino acids 63–73. We find a new helix, α_2, that comprises residues Ala 66 to Thr 74 (Fig. 1*b*) and was not found in the p21–GDP conformation[8]. Residues Ser 65, Ala 66, Met 67, Gln 70 and Arg 73 are on the outside of this helix α_2 facing the solvent. Such a helix had been predicted[37] on the basis of mutagenesis experiments, taking into account the sequence homology between EF-Tu and p21.

Oncogenic activation

Mutations in p21 amino-acid positions 12/13 and 61 have been found in a high percentage of human tumours. Additional activating mutations have been generated by site-directed or random *in vitro* mutagenesis (see ref. 4). Our three-dimensional structure shows that all of these mutants have substitutions of amino acids in regions found to be important for the binding of the guanine nucleotide. Biochemically, these mutations have an effect on the binding affinity of GDP/GTP, and/or the rate of *in vitro* GTPase activity, and/or the interaction with the GTP-activating protein GAP. It appears that at positions 12 or 13 only glycines can be tolerated because of the close spatial interaction between this loop, the phosphate residues, the effector loop λ_2 and the loop containing Gln 61. Any amino-acid substitution in the phosphate binding loop will effect the conformations of loops λ_2 and λ_4.

Gln 61, with its large functional side chain, is at the beginning of a stretch of three or four amino acids which in our structure are less well defined than the rest of the chain, suggesting a higher mobility of these residues even in the crystal. Gln 61 is close to the γ-phosphate and one could envisage that replacing it with a hydrophobic side chain could destabilize a possible interaction with the phosphate group and/or the amino acids in its vicinity. It has indeed been found that mutations Gln 61 → Val and Gln 61 → Leu have the highest transforming efficiency of all Ha-*ras* mutants at this position[41–42].

The mutations in position 12 and 61 have large opposite effects on the nucleotide dissociation rate constants of p21. Val 12, Asp 12 and Arg 12 mutants have decreased, whereas Leu 61 has drastically increased nucleotide dissociation rates. Also, the two kinds of mutants have opposite effects on the interaction with GAP. Gly 12 → Val as well as Gln 61 → Leu are able to bind to but are not activated by GAP (ref. 6). Gly 12 → Val has a lower affinity to GAP than wild type whereas Gln 61 → Leu has a higher affinity. Amino acids Gly 12 and Gln 61, which are the residues most often mutated in human tumours, are in fact in close proximity in the three-dimensional structure of the $p21_{c'}$–GppNp complex (distance between C_α's is 5.7 Å). The oncogenic activation would therefore effect the same region of the protein.

GTPase activity

It has been shown that GTP complexed to p21 or EF-Tu, is hydrolysed by direct attack from water with inversion of configuration at the γ-phosphate[43]. With the current resolution of our analysis, we cannot identify with certainty any water molecule in a position to attack the γ-phosphate. As the rate of hydrolysis, albeit slow, is at least several hundred times faster than the hydrolysis of GTP in water, functional groups could be activating the water molecule or the phosphates or both.

According to analysis so far, only Lys 16 or Gln 61 would be located close enough for this role. Changing Ala 59 to a threonine would place its side-chain hydroxyl in a position to accept the γ-phosphate in the autophosphorylation reaction observed in viral p21 Ha-*ras* (ref. 12).

GAP stimulated hydrolysis by p21 is much faster than its intrinsic GTPase activity, probably as fast as that of G_α proteins. Therefore, GAP may change the position of residues on p21 such that they can catalyse a fast GTP hydrolysis. Another possibility would be that GAP itself supplies the amino acids needed for fast hydrolysis. Figure 3*c* shows that the binding site of GAP is very open to the solvent at two regions that are on either side of the effector loop. There appears to be ample space for close contact between the two proteins around this region of the molecule.

We are currently working on the 1.5 Å resolution structure of the $p21_{c'}$–GppNp complex. We hope to be able to analyse the GTPase reaction itself in more detail from crystals of a complex between p21 and a caged GTP analogue. These crystals are catalytically active after photoactivation and the GTPase reaction can be followed by Laue techniques using synchrotron radiation (ref. 44 and work in progress). Atomic coordinates will be deposited with the Protein Data Bank when refinement at 1.5 Å resolution has been completed. □

Luminosity segregation as a constraint on the theory of biased galaxy formation

THE theory of biased galaxy formation with cold dark matter (CDM) is presently the most successful attempt to reproduce the distribution of galaxies in the Universe[1–6], permitting a reconciliation of the observed low value of the cosmological density parameter $\Omega_0 \leqslant 0.2$ with the value of unity predicted by inflation. Specific tests of the bias hypothesis, namely that galaxies are more clustered than the mass[1,2,4], however, have not yet led to definitive conclusions. Here we show that a systematic luminosity segregation effect in the clustering of galaxies is expected and provides an unambiguous test of the biased galaxy formation theory. We examine in detail how the clustering of galaxies correlates with their luminosity, using different biased models and numerical simulations[5–7]. We find that a strong effect is expected at luminosities larger than L_*, the characteristic luminosity of galaxies and that the amplitude of the predicted effect at these luminosities agrees with observations[8]. At luminosities fainter than L_*, however, strong limits have been put on this segregation effect[9]. These limits are incompatible with any biased CDM theory in which the bias parameter b_b for bright galaxies is greater than 1.5 on large scales.

Many properties of the observed galaxy distribution are well reproduced by the CDM theory of galaxy formation[10]. The predicted spectrum of the density fluctuations in the early Universe seems to be precisely that required to explain both the small-scale and large-scale structure of this distribution. To reconcile the value of the cosmic density parameter $\Omega_0 = 1$ predicted by inflation with observations, however, the galaxies must be more clustered than the total mass. This bias may be the result of physical processes that took place at the time of galaxy formation[2,4], and is also a natural feature that arises in hierarchical theories[6,11,12]. According to this bias hypothesis, the correlation function of bright galaxies ξ_{gg} is amplified with respect to the correlation function of the density field $\xi_{gg}(r) = b^2\xi_{\rho\rho}(r)$ where the bias parameter b may depend on the distance r. For bright galaxies (that is, galaxies typically brighter than the absolute blue magnitude $M = -18.5 + 5 \log h$, where h is the Hubble constant in units of $100\,\mathrm{km\,s^{-1}\,Mpc^{-1}}$) this bias b_b depends on the specific model[1,13] but must lie in the range 1.7–2.5 to make the dynamical measures of the density parameter compatible with the value of unity predicted by inflationary theories. Dwarf galaxies are expected to be more reliable tracers of the mass distribution[3] than are bright galaxies, and their bias parameter b_d should therefore be much smaller than b_b and closer to unity. Numerical simulations in the CDM scenario predict that the strength of clustering correlates with the circular velocity of haloes[6], and, therefore, with luminosity through the Tully–Fisher and Faber–Jackson relations[7]. Slowly rotating haloes ($v_c \approx 75\,\mathrm{km\,s^{-1}}$) characteristic of dwarf galaxies, correspond to a bias parameter of about unity. Therefore, a luminosity segregation effect in the clustering of galaxies is expected in this biased CDM theory, as in any biased theory.

Until recently, the observational evidence for such an effect was ambiguous. Early qualitative analyses rejected the possibility of luminosity segregation[14,15] and recent quantitative studies do not provide any clear indication[16,17]. The correlation of surface brightness with the differences in clustering has been attributed to biasing[18], but the effect remains controversial[19]. Actually, a luminosity segregation effect is observed on short scales[20–22], but this may be the result of dynamical friction, gravitational relaxation and other non-linear effects in addition to biasing. Quantitative results on scales $>3h^{-1}$ Mpc, where the density field is still linear, have recently been obtained[8,9] and can be compared directly, as below, with the theoretical predictions that result from analytical models and numerical simulations in the CDM scenario.

In biased CDM theories, bright galaxies correspond to the highest peaks of the initial density field, independent of the fact that the bias is 'natural'[6] or a result of the physics of galaxy formation[2]. As the density fluctuations generated by inflation are expected to be gaussian, the gaussian random field theory[13,23] may be used to describe the distribution of galaxies on scales where dynamical evolution is not dominant. Galaxies are identified with the peaks of the density field of amplitude $\nu_{th}\sigma_0$ above the r.m.s. level σ_0 where ν_{th} is the chosen threshold. Numerical simulations have shown that this is a good approximation[24,25] and that the associated peak–peak correlation function agrees with the observed correlation function of galaxies[1,6]. On linear scales, the bias parameter is independent of distance and is given by $b = 1 + \langle\tilde{\nu}\rangle/\sigma_0(R_s)$, where R_s is the smoothing scale associated with galaxies. Exact expressions for calculating the mean effective threshold $\langle\tilde{\nu}\rangle$ are given in ref. 13. To determine peak–luminosity relations, the sharp-threshold criterion may be too extreme, however, as the luminosity is probably not determined unequivocally by the amplitude of the peak. Nevertheless, a correlation between luminosity and the height of the peaks must remain—otherwise the galaxy distribution would no longer be biased. Thus, we introduce a selection function that gives the probability that a peak of a given amplitude $\nu\sigma_0$ actually forms a galaxy of a given luminosity, independent of the formation process. Using the selection function $t(\nu) = (\nu/\nu_{th})^q/(1 + (\nu/\nu_{th})^q)$ parameterized by the factor q (ref. 13), the sharp criterion is recovered as the parameter $q \to \infty$; finite values of q allow a dispersion in the relation between the amplitude of the peaks and the luminosity of galaxies. Adopting a smoothing scale R_s^* associated with bright galaxies, the normalization threshold ν_{th}^* for these galaxies is obtained by requiring that the number n_{pk} of peaks above this threshold equals the observed number n_b of bright galaxies $n_{pk}(\nu > \nu_{th}^*, R_s^*) = n_b$. The number of peaks n_{pk} is estimated for the CDM power spectrum[13], and n_b is normalized to $0.01h^3\,\mathrm{Mpc^{-3}}$ (ref. 26). A constant smoothing scale R_s is unphysical as the number of galaxies apparently diverges at the faint end of the luminosity function, but the total number of peaks remains finite. A simple power-law dependence $R_s \approx L^a$ is therefore assumed. If the mass associated with the peak scales as R_s^3 (ref. 23), a constant mass-to-light ratio favours $a = \frac{1}{3}$, whereas a maximum value of 0.5 is allowed by observations[10]. Following the Press and Schechter formalism[27,28], we determine the threshold ν_{th} at each luminosity by requiring that the total mass in the selected peaks matches the total mass in the galaxies

$$R_s^3 n_{pk}(\nu > \nu_{th}, R_s) \propto \int_{L(R_s)}^{+\infty} L^{3a}\Phi(L)\,\mathrm{d}L \qquad (1)$$

where $\Phi(L)$ is the luminosity function. This prescription allows the estimation of the dependence of the bias parameter on luminosity.

Figure 1 shows a comparison of predictions from the biased models described above with the observed strong luminosity segregation effect found[8] at luminosities brighter than L_* (corresponding to $M_* \approx -19.4 - 5 \log h$). The expected segregation derived from numerical simulations[6] is also shown, where the simulated circular velocity of haloes has been converted into

Present address: Institute of Astronomy, Madingley Road, Cambridge CB3 0HA, UK

luminosity through the Faber–Jackson and Tully–Fisher relations[22], taking into account the proper number density of galaxies of a given velocity or luminosity. Given the uncertainties in the measures of bias, theoretical predictions with $b_b \approx 2$ agree well with the observed trend illustrated in Fig. 1, whereas models with low values of b_b and q (corresponding to large peak-luminosity dispersions) fail to reproduce the strong segregation found at high luminosities. The effect remains even when a gaussian dispersion is introduced into the velocity–luminosity relation from numerical simulations. It can also be observed that both models and simulations predict a non-negligible effect at luminosities fainter than L_* independent of the choice of the parameters. As shown below, this may constitute a serious problem for biased CDM scenarios as no significant luminosity segregation has been observed at luminosities fainter than L_* (refs 8, 9).

Because of the small amplitude of the predicted effect at low luminosities, it is preferable to use the ratio α of the cross-correlation functions, as this measure of the segregation effect is much less sensitive to sampling fluctuations and to normalization uncertainties in the measure of the correlation function[9,29]. The cross-correlation of galaxies brighter than L_1 with galaxies brighter than L_2 is $\xi_{L_1L_2}(r) = b(L_1)b(L_2)\xi_{\rho,\rho}(r)$. The relevant quantity to be compared with observations is $\alpha(L_2, L_1) = b(L_1)/b(L_2)$ where the luminosity L_1 is one magnitude fainter than L_2 (ref. 9). A large set of models was calculated, exploring the full parameter space ($a = 0$–0.5; $q = 4$–∞; $R_s = 0.05$–$0.5h^{-1}$ Mpc). The adoption of different luminosity functions for present galaxies makes only a small difference.

Whereas the behaviour at bright luminosities depends strongly on the selection function, the trend of α is remarkably stable at fainter luminosities and depends essentially on b_b, the parameter on which reliable conclusions can be based. This arises from the fact that a correlation between high peaks and bright galaxies always exists in any biased theory. As illustrated in Fig. 2, the only model that is not strongly excluded by the data has $b_b \approx 1.5$. This extreme model predicts $b^2(-19)/b^2(-15) \approx 1.27$, which is marginally consistent with the observed limits of $b^2(-19)/b^2(-15) \approx 0.993 \pm 0.145$, derived from volume-limited

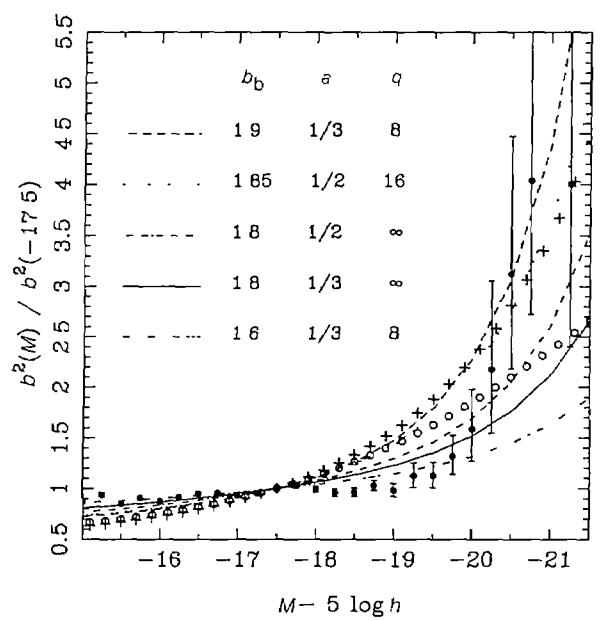

FIG 1 Comparison of the observed variation (filled circles) of the bias parameter[8] at $4h^{-1}$ Mpc (normalized to its value at magnitude $-17.5 - 5 \log h$) with theoretical predictions Numerical simulations[6] are represented by open circles (one-magnitude gaussian dispersion in the circular velocity–luminosity relation) and crosses (no dispersion) The lines correspond to different biased models as indicated in the key

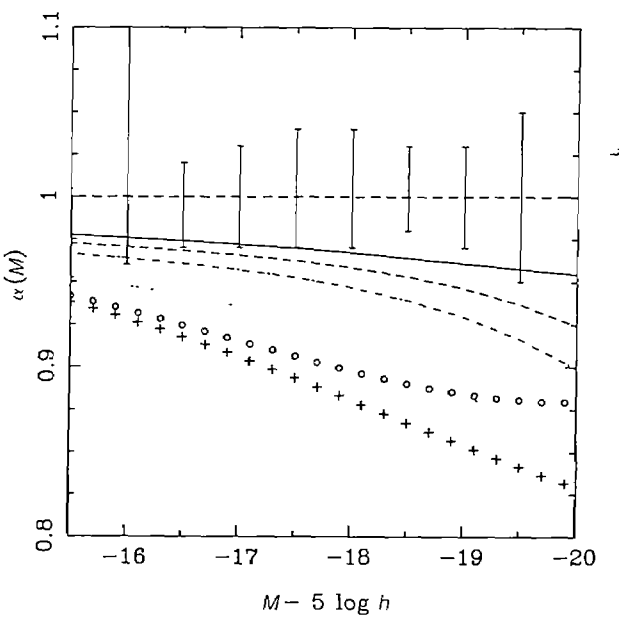

FIG 2 Comparison of the observed variation of the alpha ratio[9] with biased models (full $b_b = 1\,5$, $a = \frac{1}{3}$, $q = 8$, dashed $b_b = 1.7$, $a = \frac{1}{3}$, $q \to \infty$, dash-dotted $b_b = 1\,8$, $a = \frac{1}{3}$, $q \to \infty$; dotted, $b_b = 1\,9$, $a = \frac{1}{2}$, $q = 8$) and numerical simulations (as in Fig 1) The value $\alpha = 1$ (thick dashes) is the most likely to be compatible with observations

subsamples in the survey[26], and extensively discussed in ref. 9 Figure 2 shows that the absence of segregation ($\alpha = 1$) is much more likely than any biased model. It is possible to obtain extreme models which are compatible with the data at a significant level, but their bias parameter b_b is always <1.5. For instance, a smoothing scale as small as $R_s \leq 0.05h^{-1}$ Mpc may be used for bright galaxies, but then the baryonic fraction enclosed in these fluctuations would be very small ($\leq 2.5 \times 10^{-4}\Omega_0$) and would require an important secondary infall, which seems unlikely

The agreement of biased CDM models of galaxy formation with a large set of observations is impressive, despite some discrepancies with recent observations of large-scale phenomena. In particular, the correlation length of clusters[30] and large-scale streaming motions[31] may well be in conflict with this theory, but the interpretation of these observations is still uncertain[32]. Even if these observations are interesting tests of the density spectrum shape, they do not directly test the bias hypothesis. The dependence of the galaxy clustering on luminosity seems to be inherent to any theory in which galaxies are not distributed as the mass. Therefore, the luminosity segregation effect provides a critical test that does not depend on the details of the physical processes that lead to galaxy formation, but follows directly from the hypothesis that galaxies are more clustered than the underlying mass. We have shown that biased theories in the CDM scenario with b_b larger than 1.5 are in clear conflict with observations, but the resolution of the cosmic density parameter requires $b_b \approx 2.5$ (ref. 1). It is nonetheless desirable to extend the observational analysis to larger samples before drawing any definitive conclusions, as the presently available catalogues offer only a small volume for the analysis of the effect. Also, the hypothesis that the clustering in bright galaxies does not match the mass distribution is still possible on short scales because, in the CDM theory, the fraction of total mass in visible baryons is small. Nevertheless, we have found limits on the luminosity segregation effect in the clustering of galaxies on large scales that are incompatible with the present versions

of the theory of biased galaxy formation with cold dark matter □

THE discovery of broad emission lines in polarized light from the type 2 Seyfert galaxy NGC1068 led Antonucci and Miller[1] to postulate the existence of a type 1 Seyfert nucleus shrouded from our direct view by a torus of molecular gas. Theoretical development[2] of this idea included the suggestion that low-angular-momentum clouds in the torus are captured by the central source, fuelling the observed activity. The difficulty in applying this model to all active galactic nuclei (AGNs) is the lack of convincing evidence for molecular gas in 'bare' nucleus objects such as the quasar 3C273, which exhibits a simple power-law continuum and no excess of thermal dust emission. Here we present observations, made during the course of a survey for rotation and vibration lines of H_2 emission from type 1 Seyferts and quasars, of molecular hydrogen emission from 3C273. This is the first time such emission has been seen from a radio-loud quasar.

The H_2 line used was the $v=1$–0 S(3) transition (rest wavelength 1.957559 μm (ref. 3)), instead of the $v=1$–0 S(1) line which has been well studied and is one of the brightest H_2 emission lines. We chose this line because the frequency of redshifted $v=1$–0 S(1) line (2.122 μm) falls outside the transmission window of the Earth's atmosphere.

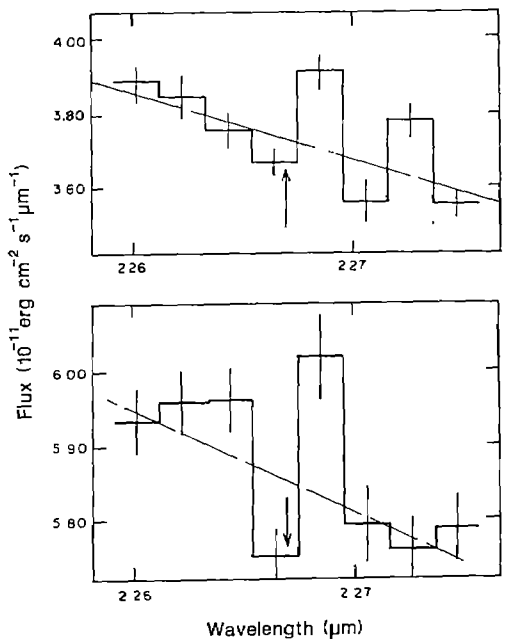

FIG 1 Spectra taken in December 1986 and February 1988 (top and bottom respectively) near the position of the $v=1$–0 S(3) lines. Uncertainties correspond to 1σ statistical noise. The data are sampled with one point per instrumental resolution element. The straight line is the continuum level used to calculate the line flux. The arrow shows the predicted line position based on optical data.

We observed the line on two occasions, 1986 December 27.36 and 1988 February 2.33 (UT) using the Cerro Tololo Inter-American Observatory 4-m telescope equipped with the infrared spectrometer[4] (IRS). The broad-band K-magnitudes were obtained simultaneously, using the monitor channel of the IRS. A 3.4×6.8 inch slit was used (where the first dimension was parallel to the dispersion axis). The frequency resolution of the IRS corresponds to a velocity resolution of 290 km s^{-1} per detector. We used a xenon or an argon lamp to calibrate the wavelength scale before each integration and achieved an accuracy of 10% of the resolution (30 km s^{-1}). The spectroscopic data is sampled with one point per instrumental resolution element. The Am-type star BS4167 (ref. 5) was used to calibrate the flux scale and correct for atmospheric extinction. The spectroscopic data were obtained on nights when the photometric condition was good and the accuracy of the flux is 5% or better. There are no stellar absorption features or serious telluric absorptions in the standard spectrum.

Figure 1 shows the H_2 spectra; the arrow shows the line position predicted from the optical data[6]. The straight line in the figure is the continuum level used to obtain the line flux given in Table 1. The continuum line is a linear fit function to assumed continuum points on either side of the emission line, weighted by the inverse squares of the uncertainties.

During the December 1986 run, 3C273 was in a quiescent state and its K-magnitude was 9.74 or 80 mJy whereas on 2 February 1988, its K-magnitude was 9.50 or 100 mJy. At the end of January 1988, the J-band flux was 10% higher than that of the quiescent state[7]. It continued to increase gradually in February, reaching maximum brightness in mid-March[7]. Our record of the increase in the K-flux indicates that the luminosity from 1.2 μm to 2.2 μm started to increase simultaneously during this event. The continuum near the H_2 line brightened by 0.49 mag (see Fig. 1), 0.25 mag more than the integrated K-flux.

The $v=1$–0 S(3) line was detected in each run. Because of the low signal-to-noise ratios we are not certain that the line fluxes in both runs remained constant. It is probable, however, that the line fluxes did not change during the flare, because the

‖ To whom correspondence should be addressed

molecular clouds that are the source of the H_2 emission are probably located at a distance >1 pc from the central non-thermal source[2]. The spectra of the two runs (see Fig. 2) were combined by reducing the continuum level in February 1989 spectrum by 0.49 mag and assuming the line flux to be constant. The resultant spectrum has a $v=1$–0 S(3) line flux of $(4.14\pm0.58)\times10^{-15}$ erg cm^{-2} s^{-1}. The continuum of Fig. 2 refers to that in the quiescent state. Scaling the entire February 1988 spectrum by 0.49 mag results in a low line flux of $(3.20\pm0.58)\times10^{-15}$ erg cm^{-2} s^{-1}. The predicted line position is offset by -200 km s^{-1} from the centre of the line pixel. This may be the result of an uncertainty in the determination of the velocity shift of the optical lines or to differences in the velocity between optical and H_2 emission lines. We note that the slope of the continuum is steep. This may be the result of the broad wing of the Brδ line (1.94456-μm rest wavelength) which is only 2,000 km s^{-1} to the blue of the $v=1$–0 S(3) line.

We assume the ratio of $v=1$–0 S(3) to $v=1$–0 S(1) fluxes to be unity in order to compare our results with other observations. Within the uncertainty of the line flux, this assumption is consistent with the predictions from shock excitation[6,9] or X-ray heating[10] models, both of which are plausible mechanisms for H_2 excitation in AGNs[4,11]. This ratio is 0.77 (ref. 12) in the merging galaxy NGC6240. The mass of hot infrared-emitting H_2 molecules can be roughly estimated by assuming a temperature of 2,000 K for the H_2 molecular gas[13]. It is $8\times10^4\,M_\odot$ at a distance of 630 Mpc assuming a Hubble constant $H_0=75$ km s^{-1} Mpc^{-1} and a deceleration parameter $q_0=0$.

Molecular hydrogen emission, direct evidence for the presence of a considerable mass of hot molecular gas in 3C273, has not been previously reported. Here we discuss possible relationships between H_2 emission and AGN activity in 3C273. We have found[4] that the molecular hydrogen emission is generally stronger in dusty AGNs such as type 2 Seyferts than in H II-region galaxies when normalized by the IRAS far-infrared flux[14]. This separation is clear in the subsample observed with a small aperture the diameter of which is $\leq6\%$ of the isophotal galaxy diameter defined by a surface brightness of 25 mag arcsec^{-2}; with increasing aperture the differences between AGN and H II region galaxies disappear. The ratio of the H_2 line to the far-infrared flux in 3C273 is 3.8×10^{-5}, which is about the maximum for dusty AGN and H II region galaxies. For dusty AGNs, the far-infrared flux is a measure of the quantity of warm dust or energy input to molecular clouds, and thus the ratio of the H_2 line to far-infrared flux is a measure of the efficiency of H_2 excitation. The observed far-infrared flux of 3C273 should be corrected because 3C273 seems to be completely dominated by non-thermal emission in the far-infrared. Extrapolating the power law from the data between millimetre and submillimetre wavelengths[6], we estimated the upper limit of the thermal contribution to the observed far-infrared flux to be 15%. If we correct

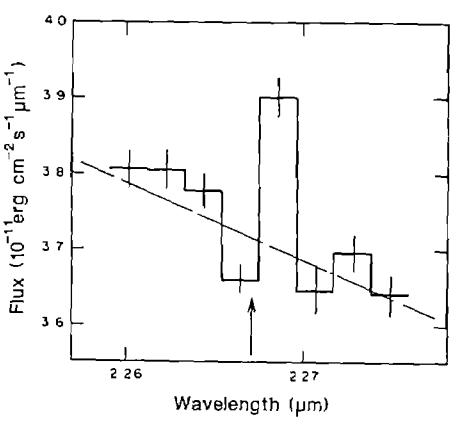

FIG 2 As for Fig. 1, but for the combined spectrum of the $v=1$–0 S(3) line (see text)

TABLE 1 Observations of 3C273

Date (UT)	K-magnitude	$v=1$–0 S(3) (10^{-15} erg cm^{-2} s^{-1})
1986 December 27 36	9 74	4 6±1.3
1988 February 2.33	9.50	3.9±1 4
Average (from combined spectrum)		4.1±0 6

for this effect, the efficiency for H_2 excitation or the ratio of I to warm-dust luminosities becomes $\geq2.5\times10^{-4}$, which is tl largest efficiency ever observed. Hence, it is quite likely that I emission in 3C273 is closely related to the activity of the centr source.

If molecular clouds exist near the central source as suggest by the molecular torus models[2], the clouds directly heated l radiation from the central source would be hot enough to radia H_2 emission and thermal continuum peaked in the near infrare The prominent bump in the continuum at 3.5 μm may be releva here because it is believed to be the result of either free-free thermal dust emission. The blackbody radiation from hot du fits[15] the 3.5-μm bump better than free-free emission from region of density 10^{11} cm^{-3} (ref. 16). Barvainis[17] develope models to account for the 3.5-μm bump of 3C273 in terms thermal radiation from dust heated by an optical-ultraviol continuum. In his model, grains are heated to $T=1{,}500$ K at radius of ~1 pc from the central source. Inside this radius, grai are evaporated by intense ultraviolet radiation. The mass of th grains in 3C273 calculated from these models is $7\times10^2\,M_\odot$ $T=320$–1,500 K. If the dust-to-gas ratio is similar to the Milk Way and the hot molecular gas and the hot dust are mixed, ou results are consistent with his estimates. It is uncertain that th H_2-emission region in 3C273 is located at such a close distanc from the central source, however, because the slit used in ou observations corresponds to a physical size of 10×20 kpc. W note that observations[18] of 18 type 1 Seyferts and quasars sugge that the spatial extent of H_2-emission regions is small or ur resolved, which is in contrast to type 2 Seyferts and H II regio galaxies, the H_2-emission regions of which are considerabl extended[12]. This is only circumstantial evidence for the relatior ship between H_2 emission and the dust-emission models, an thus it is important to observe the H_2 emission of nearby typ 1 Seyferts that have no thermal emission in the far-infrared b using a small aperture. Through the idea[2] that low-angula momentum clouds are captured by (and therefore feed) th central source, the H_2 emission from this class of objects ma help us to understand the fuelling of AGNs[19].

VLF emission bursts in the terrestrial and venusian nightside troughs

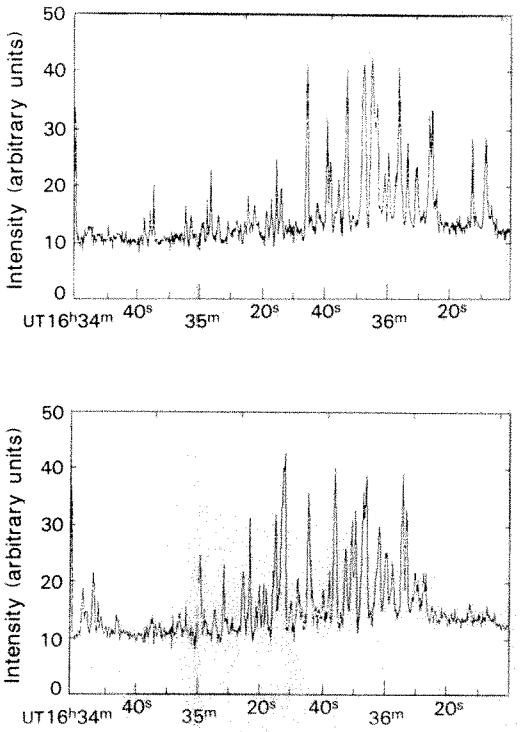
Kaichi Maeda & Joseph M. Grebowsky

NASA/Goddard Space Flight Center, Greenbelt, Maryland 20771, USA

THE existence of very-low-frequency (~100 Hz) electric-field bursts in the nightside Venus ionosphere has been commonly assumed to be evidence for lightning, by analogy to the Earth where some of the whistler-mode radiations above the ionosphere originate from lightning[1–3]. Non-lightning sources for Venus whistler-mode waves have been ignored. VLF emission bursts not associated with lightning are frequently observed over the terrestrial polar ionosphere[4–6]. One type, saucers, are whistler-mode wave emissions that propagate upwards along magnetic-field lines[5,6]. Here we show that the 100-Hz emission bursts in the venusian nightside ionosphere are remarkably similar to those of the terrestrial VLF saucer emissions in terms of their spatial and temporal characteristics and the properties of their magnetoplasma environment. We therefore propose that the generation mechanism for such VLF saucers[6,7] should be considered as a viable alternative to lightning as a source of venusian ionospheric whistler-mode emissions.

The VLF emission data obtained from terrestrial polar-orbiting satellites show bursts of signal. Some of these signals are V-shaped in wide-band data with frequencies below the lower of the local electron gyrofrequency or plasma frequency, that is, the missions are whistler-mode waves. Two kinds of whistler modes—V-shaped saucers and V-shaped hiss—are observed[4–6]. The hiss in the polar region is related to intense electron precipitation and is Cerenkov radiation from auroral electrons. Hiss propagates downwards. The V-shaped saucer which propagates upward along magnetic-field lines, however, is not related directly to auroral-particle precipitation and is observed above or within nightside polar ionospheric troughs[5]. The saucers can be produced by the cyclotron instability of an anisotropic distribution of hot electrons interacting within the polar upper ionosphere[7] or by suprathermal electrons streaming upward through the background plasma[6].

Figure 1 shows the wide-band a.c. electric-field data of a V-shaped saucer event observed by the DE-1 satellite on 27 January 1984. The a.c. magnetic-field data are not presented but the V-shaped emissions in this wide-band data are known to be whistler-mode electromagnetic waves[5]. There are also several sharp slanted emission lines appearing around the main V-shaped event, the apex of which appears at 16:35:40 UT. These emission bursts are one side of several V-shaped saucers, the apexes of which occur around 16:35:20 UT. The detection of only one side, or only part of one side, of these V-shaped saucers from a high-velocity satellite indicates the short durations of the generation of these emissions, that is, unsteady plasma conditions in the source region. These burst features are attributed to characteristics of the source electrons and of the irregularities in the plasma density distribution in the polar upper ionosphere. The irregularities in the plasma density are sustained predominantly only in the night-time ionosphere. The large aperture angle of these background features is a manifestation of the large distance of the sources of these emissions from the satellite[6,7]. These events occur in the nightside polar ionospheric troughs, as indicated by the very small ratio of the plasma frequency f_p to the electron gyrofrequency f_g, that is, $f_p/f_g \ll 1$. Similar findings that indicate the appearance of VLF



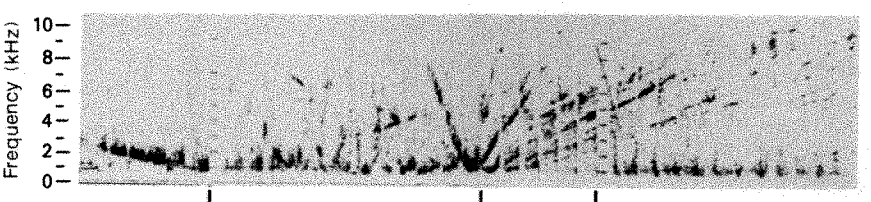


FIG. 2 The microdensitometer trace of the wide-band data (Fig. 1) at constant frequencies of 4 kHz (top) and 6 kHz (bottom) with 4% bandwidth.

FIG. 1 The wide-band a.c. electric-field data of V-shaped saucer with several V-type emission events on 27 January 1984 observed from the DE-1 satellite. Under the data are; time; h, satellite altitude; R, radial distance of the satellite normalized by the Earth's radius (R_E=6,371 km); L, dipole-field parameter; Lat., invariant latitude; MLT, magnetic local time; f_g, electron gyrofrequency; f_p, electron plasma frequency; ratio f_p/f_g.

saucers in the nightside polar ionospheric troughs were made by the OGO-6 experiments (K.M. and J.M.G., manuscript in preparation).

The 'bursty' nature of V-shaped saucers shown in Fig. 1 can be seen more clearly from Fig. 2 where the relative intensity variations of the emission within fixed frequency bands are presented; this is the type of electric-field measurements made from the Pioneer Venus Orbiter (PVO), presented later. This presentation is produced by scanning the wide-band data shown in Fig. 1 at frequencies of 6 kHz and 4 kHz (4% bandwidth) with a microdensitometer. Here, the slit width (pixel size) of the microdensitometer corresponds to the bandwidth of the VLF detector. These figures show the 'bursty' nature of the saucers. Some of the spiking in Fig. 2 is associated with the satellite-spin modulation of the wide-band data shown in Fig. 1, and can be easily distinguished by comparing upper and lower figures, that is, the natural bursts appear at different instants at 4 kHz and 6 kHz, but the 3-s modulation that results from the satellite's 10-r.p.m. spin occurs at the same instants in both figures.

An example of the VLF emission data from the PVO within the nightside venusian ionosphere is presented in Fig. 3. The Orbital Electric Field Detector (OEFD) measures intensities within four frequency bands that have a 30% bandwidth centred on 31, 5.4, 0.730 and 0.100 kHz. On the bottom, the total ion density N_T (ions cm^{-3}) measurements made simultaneously by the orbiter ion mass spectrometer (OIMS) are shown. This figure shows an association between the 100-Hz emissions occurring in the absence of higher-frequency emissions and a plasma trough—this is characteristic of the emission[8,9]. It should be noted that the 100-Hz emission is the only possible whistler-mode wave among the venusian ionospheric emissions observed[2] by the four-channel plasma-wave instrument (OEFD) aboard the PVO.

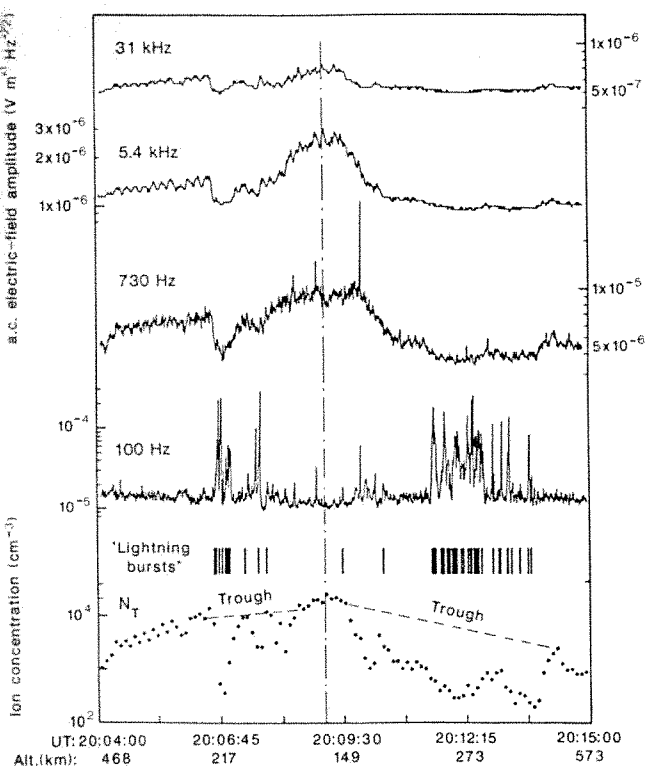

FIG. 3 Pioneer Venus orbiter (PVO) data of VLF emissions at 100 Hz, 730 Hz, 5.4 kHz and 31 kHz. The a.c. electric-field amplitude (V m^{-1} Hz$^{-\frac{1}{2}}$) appears on the left-hand axis and right-hand axis alternately). The total ion density (cm^{-3}) observed by the OIMS are also shown by dots for a period 20:04:00–10:15:00 UT on orbit 66. A dot-dashed vertical line in the centre indicates the passage of the periapsis. The altitude of PVO above the venusian surface is indicated under the time annotations. Emissions identified[9] as lightning bursts based on OEFD data are shown by vertical lines under the 100-Hz intensity curve.

The characteristics of the 100-Hz band emissions are clearly different from the other three emissions of higher frequency (Fig. 3). The enhanced 100-Hz emission bursts are observed within the ion troughs which exist only in the nightside venusian ionosphere and within which the magnetic field is enhanced, projected toward the planet and is characterized by a gyrofrequency that is generally >100 Hz. Unlike the 100-Hz emissions, the emissions above 0.73 kHz are enhanced when the PVO approaches its periapsis, which is consistent with local CO_2 impact generation of ion acoustic waves[10]. The spike-like 100-Hz emissions that were classified as lightning bursts[9] are shown by vertical lines under the 100-Hz emission.

For the terrestrial saucer emissions, the frequency can extend from the lower hybrid resonance frequency[6] that is of the order of 100 Hz up to the electron gyrofrequency or plasma frequency (both of the order of several hundred kHz). This is the domain of the whistler-mode wave in the terrestrial polar ionosphere and magnetosphere. Because Venus does not possess an intrinsic magnetic-dipole field, the radial nightside static magnetic fields are the interplanetary magnetic fields (IMF) brought in by the solar wind. The corresponding electron gyrofrequencies that define the upper limit of venusian whistler-mode emissions are of the order of 100 Hz for these rather weak induced fields.

A comparison of the variation of the near monochromatic intensities of the terrestrial VLF saucers shown in Fig. 2 to the 100-Hz Venus emissions shown in Fig. 3 shows a striking similarity in the burst characteristic of these two emissions. Other close similarities in features and characteristics of these emissions exist and are listed in Table 1. The lack of confirmation of the association of particle precipitations with terrestrial saucers and PVO 100-Hz emissions can be ascribed to the limitation of measurements; the existence of short-lived narrow beams of electron precipitation during these emission events cannot be ruled out at present. There are theoretical implications of this situation and connections with other phenomena such as the electrostatic shocks and the polar plasma cavities outside of the auroral activities in the terrestrial polar magnetosphere[10–12].

TABLE 1 Impulsive VLF properties

	Terrestrial VLF saucer	Venusian 100-Hz emission
Emission characteristics	$f < (f_g, f_p)_{min}$; bursts; electromagnetic[4–6]	$f < f_g$ (which is $< f_p$); bursts; electric-field component normal to static magnetic field[1,3]
Association with particle precipitation	Unconfirmed[5,6]	None evident
Propagation	Upward along magnetic field; right-handed polarization; whistler mode but weak magnetic component[5]	Upward presumed; polarization unestablished but not inconsistent with whistler-mode propagation[2]
Location	Nightside in ionospheric troughs where magnetic field is radial[5–7]	Nightside in ionospheric holes where magnetic field is radial[1–3,8]
Duration	Individual emissions are a fraction of a second long; one event with an apex is <1 min (refs 5, 6)	Individual emissions are <0.5 s; event duration nominally <1 min (ref. 1)
Related phenomena	Electrostatic shock; narrow upward ion beams; suprathermal conical ion distributions[11,12]	Suprathermal ions around the ion holes[8]

On the basis of the comparison of the known features of the ɛrrestrial saucers and the venusian 100-Hz whistler bursts, it ɛems natural to conclude that the latter emissions in the ·enusian nightside ionospheric troughs can arise from mechan-ɨms similar to production of VLF saucers in the terrestrial ɨightside polar ionospheric troughs. These mechanisms for the 00-Hz emission are just as plausible an explanation as that roposed by Scarf and Russell[1-3] who used analogies to terres-ıal lightning events to associate the emissions with volcanic ctivities in high mountain clusters on the venusian surface. The alidity of either of these mechanisms can be easily verified if ɛequency-time spectrograms (wide-band data) of VLF ɨissions in the nightside venusian ionosphere are obtained. ·Vithout such observations it will be very difficult to distinguish ghtning disturbances from ıonospheric generation of impulsive ·histler bursts of energetic electrons. □

vidence for cleavage of polymer ɔhains by crack propagation

ɭ. R. Brown*, V. R. Deline* & P. F. Green†

IBM Almaden Research Center, 650 Harry Road, San Jose, ɜlifornia 95120-6099, USA
Sandia National Laboratories, Albuquerque, New Mexico 87185-5800, ɔA

ʻRACK propagation in polymers is a topic of considerable import-ıce to the technological application of these materials. In high-olecular-weight glassy polymers, crack propagation is normally ssumed to require the breaking of covalent bonds in polymer ıains that span the crack path, as opposed to chain slip and ɨsentanglement. The fraction of such broken chains in a bulk ımple would be very small, however, so that there is little direct ·idence for this chain breakage[1]. Interfaces between immiscible ɔlymers are often very weak, but can be strengthened by the ɾesence of a diblock copolymer (a polymer in which each molecule ɔnsists of a block of one polymer bonded to a block of a different ɔlymer) for which each of the two blocks is miscible with one of ıe homopolymers[2]. The diblock copolymer is thought to organize the interface and so 'stitch' the homopolymers together. Here ɜ show that crack propagation along the interface between the ɔmopolymers involves breaking all the copolymer chains at a ɔint in the region of the junction between the two blocks. Thus ɜ demonstrate both that the block copolymer does indeed organize the interface and that fracture involves the breaking of polymer ıains. This information may suggest means by which the ɾhanical properties of polymer blends could be systematically ɨproved.

Diblock copolymers can be made with one or both of the ocks deuterated. In our experiment we place partially or fully ɜuterated block copolymers at the interface between two ɔmopolymers, join the homopolymers at elevated temperatures

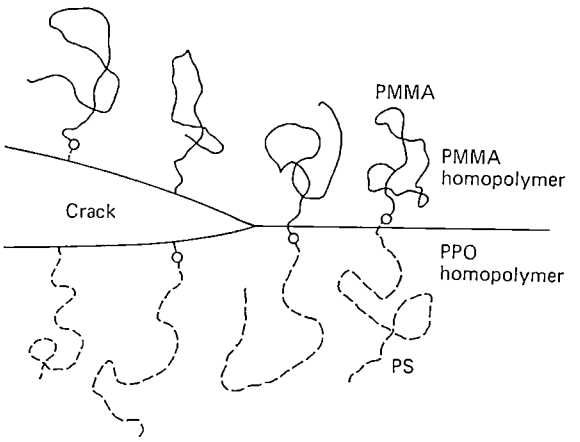

FIG 1 A schematic view of the partly fractured interface with diblock-copolymer molecules present The junction of the diblock is represented by a circle

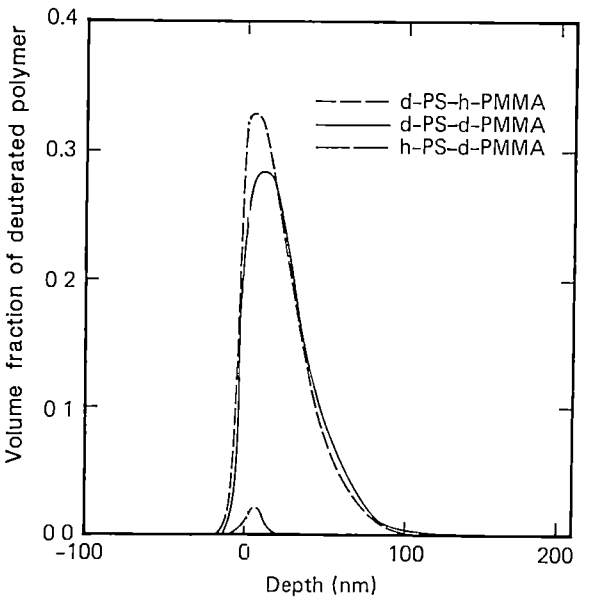

FIG 2 SIMS deuterium profiles under the PPO fracture surface for the three block copolymers. Films of h-PS of 50-nm thickness were floated onto the sample from a water surface before the depth profiling This was necessary to establish a constant etching rate before depth profiling started into the sample. The depth zero was chosen as the position of a thin gold layer between the h-PS cover layer and the sample

and then fracture the sample along the interface at room temperature. We use secondary-ion mass spectrometry[3] (SIMS) and forward-recoil spectroscopy[4,5] (FRES) to measure the deuterium on the fracture surface. If the block copolymer breaks at its junction point, then deuterium will be seen on both surfaces when both blocks of the copolymer are deuterated but only on a single surface if one block is deuterated. The positions of the propagating crack and the diblock copolymer are shown schematically in Fig. 1.

Poly(2,6-dimethyl-1,4-phenylene oxide) (PPO) and poly-(methylmethacrylate) (PMMA) are immiscible homopolymers, and the interface between them has a low interfacial toughness of $\sim 1.5\ J\ m^{-2}$. PPO is miscible with polystyrene (PS) so we expect PS-PMMA diblock copolymers to strengthen the interface between PPO and PMMA homopolymers. Such strengthening indeed exists; the presence of a 25-nm-thick layer of a

symmetric diblock of total relative molecular mass 280,000 (280K) gives an interface with a toughness of ~15 J m^{-2} (ref.1), a value both significantly higher than that of the bare interface and considerably lower than that for cohesive failure of the homopolymers. The latter point is important as the weakness of the interface means that the fracture surface do not become highly deformed or crazed in the fracture process and so are suitable for analysis by SIMS and FRES.

The SIMS depth profiles for deuterium at the two fracture surfaces (Figs 2 and 3) show that an equal amount of deuterium exists on both surfaces when the (d-PS)-(d-PMMA) diblock is used (here d and h will indicate deuterated and non-deuterated polymers). For the (d-PS)-(h-PMMA) diblock, most of the deuterium is on the PPO fracture surface whereas most deuterium is on the PMMA surface for the (h-PS)-(d-PMMA) diblock. Clearly the diblock copolymer was at the interface and broke near its centre point when the specimen was fractured. These results were confirmed with the use of FRES (Fig. 4) which showed that the PPO half of the fractured sample contained PS but no observable PMMA from the diblock. (We note that the PS side of the block copolymer extends deeper into the PPO homopolymer than does the PMMA side of the copolymer into the PMMA homopolymer. This effect is caused by the favourable enthalpy of mixing between PS and PPO.)

Integration of the deuterium signal from SIMS profiles gives the proportion of diblock on the 'wrong' sides of the interface. The fraction of the PS on the PMMA side was 0.7% whereas 2.1% of the PMMA in the block copolymer was on the PPO side. If the distribution of fracture positions along the chain is assumed to be gaussian, one can estimate the width and position of the centre point of the distribution from a knowledge of gaussian integrals. For diblock chains of total relative molecular mass ~300K, the standard deviation of the distribution of fracture positions was found to be just 1.6% of the chain length (4.5K). The mean fracture position (centre of the gaussian) was 0.7% of the chain length into the PMMA from the junction point. These results show that 70% of the chains broke within a chain length of ~9K centred at a point in the PMMA just 2K into the PMMA from the junction between the PS and PMMA. Such accurate bisection of the copolymer chains shows that the block copolymer must be well organized at the interface with its junction accurately placed at the PPO/PMMA interface.

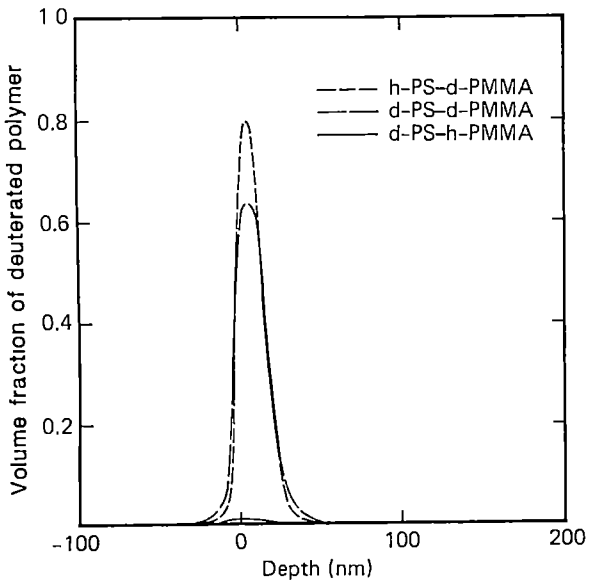

FIG 3 SIMS deuterium depth profiles taken into the PMMA side of the fracture surface. An h-PS cover layer was used here as described for Fig. 2. Integration of the (d-PS)-(d-PMMA) curves for both fracture surfaces gave approximately the same amount of deuterium on each side.

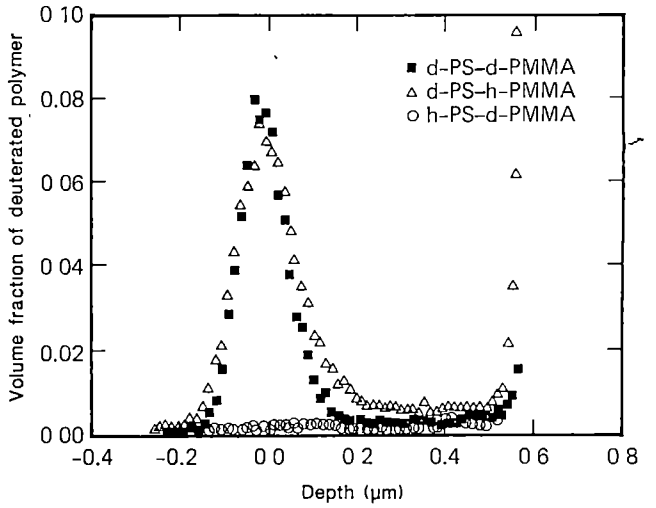

FIG 4 Depth profiles obtained by FRES for deuterium from the PPO fracture surface The limited depth resolution of the FRES technique makes it impossible to observe the shape of the profile.

Although the entanglement spacing of a polymer is obtained from its rheological properties at temperatures above the glass transition temperature T_g, there is excellent evidence[6] that the entanglement density controls the crazing and failure of a glassy polymer. Some recent models[7,8] of crazing and failure in glassy polymers assume that the chains are loaded by stress transfer from adjacent chains at discrete entanglement points. This assumption implies that, in the copolymer, most failure should occur within a length corresponding to one entanglement spacing. The relative molecular mass between entanglements M_e is 9K (ref. 9) for PMMA. The M_e for PS in PPO is not known but, as the concentration of PS at the interface on the PPO side is ≥30%, it is probably not very different from the mean value of 7K measured[10] for a 1:1 blend of PS and PPO. These values for M_e agree very well with the measured 9K length for 70% of the failures indicating that entanglement spacing does indeed control the length of the highly stressed chain at the crack tip.

Our experiment does not allow us to determine whether the copolymer chain breaks in more than one place. It is quite possible that the PMMA side of the copolymer forms a number of loops into the PPO. These loops, if they exist, must pull out during the crack propagation, perhaps by fracturing at their apexes, if relatively long. It would be, in principle, possible to detect this additional chain breakage by heating the broken samples above T_g and measuring the diffusion constant of the broken deuterated copolymer molecules into the matrix. This diffusion constant should depend on the relative molecular mass of the labelled chains. □

Determination of three-dimensional lattice connectivities in zeolites using natural-abundance ^{29}Si two-dimensional NMR and the direct observation of ^{29}Si–O–^{29}Si couplings

C. A. Fyfe*†, H. Gies*, Y. Feng* & G. T. Kokotailo*

* Department of Chemistry and † Department of Pathology, University of British Columbia, Vancouver, British Columbia, Canada V6T 1Y6

In recent years, high-resolution solid-state NMR spectroscopy has emerged as a complementary technique to diffraction measurements for the investigation of solid-state structures, the former probing local environments and the latter long-range periodicities and orderings. For zeolites, where the small size of the particles limits the quality of the diffraction data, information from NMR studies has been particularly valuable. Here we demonstrate that two-dimensional COSY (correlation spectroscopy) NMR may be used for natural abundances of ^{29}Si in the solid state to establish the three-dimensional lattice connectivities within these structures, and we present the direct observation of ^{29}Si–O–^{29}Si couplings. These measurements greatly extend the potential of the NMR method in the study of zeolites and should be applicable to a variety of other three-dimensional lattice structures containing NMR-active nuclei.

Zeolites are open-framework structures, constructed from SiO_4^{4-} and AlO_4^{5-} tetrahedra, that usually contain channels and cavities and are of widespread interest because of their unique sorptive and catalytic properties[1-4]. Although they are highly crystalline, they are usually microcrystalline with dimensions of only a few microns, precluding the straightforward use of single-crystal diffraction techniques and structural refinements must usually be attempted from more limited powder diffraction data. (We note that the information from powder diffraction data may be improved by the use of synchroton X-ray sources, which makes it possible to work with much smaller crystals[5], and Rietveld analysis.)

High-resolution solid-state NMR spectroscopy has emerged as a complementary technique for these systems[6,7]. In the case of highly siliceous analogues, sharp resonances are observed, the numbers and relative intensities of which reflect the number and relative occupancies of the crystallographically inequivalent lattice sites in the unit cell, thus establishing a direct link to diffraction measurements[8]. In solution NMR studies, the power of the technique for structural investigations has been greatly enhanced by the development of two-dimensional experiments such as COSY, which establish bonding connectivities between atoms within a molecular structure[9-13]. In principle, it should be possible to perform similar experiments in the solid state where, in the case of three-dimensional lattices such as zeolites (in contrast to the case of molecular crystals[14]), the three-dimensional connectivities should be obtained. We have demonstrated[15] the general viability of this approach, showing that it yielded the expected connectivities for the known lattice structure of zeolite ZSM-39. In that study, however, the entire lattice was enriched to ~85% in ^{29}Si to increase the signal-to-noise ratio and enhance the connectivities that result from the ^{29}Si–O–^{29}Si interactions. Such high levels of enrichment will not generally be possible because of the high cost involved. Here we show that the limiting experimental factors identified in our previous work may be used to choose the optimum experimental conditions and that natural-abundance experiments on these systems are indeed feasible, making the technique quite generally applicable.

TABLE 1 Tetrahedral atom sites, their occupancies and connectivities for the asymmetric unit in zeolite ZSM-12

T-site	occupancy	connectivities
T_1	1	$2T_2.2T_3$
T_2	1	$2T_1.2T_4$
T_3	1	$2T_1.1T_5.1T_7$
T_4	1	$2T_2\ 1T_5.1T_6$
T_5	1	$1T_3\ 1T_4\ 2T_6$
T_6	1	$1T_4.2T_5\ 1T_7$
T_7	1	$1T_3\ 1T_6.2T_7$

Figure 1 shows one projection of the lattice structure of zeolite ZSM-12. The structure is approximately that originally reported[16] although a recent refinement[17] of synchrotron powder X-ray data established the unit-cell symmetry to be $C_{2/c}$ with a doubling of the c cell dimension to 24.3275 Å. The number of crystallographically inequivalent silicons in the unit cell is unchanged, there being seven tetrahedral (T) sites with equal occupancies as indicated in Fig. 1. This is reflected in the ^{29}Si magic-angle-spinning NMR spectrum which shows seven clearly separated resonances of equal intensity. Table 1 lists the connectivities predicted from the structure.

In previous experiments with highly isotopically enriched materials we ascertained that the T_2^* (spin–spin relaxation time) value (as reflected in the linewidth in these samples) was the limiting factor in these experiments; it determines the maximum time that can be used for the frequency encoding and evolution steps quite independently of the magnitude of the J-couplings anticipated. By careful shimming and setting of the magic angle, linewidths of ~8–10 Hz were obtained for the ZSM-12 sample. A two-dimensional COSY experiment[18] was carried out consisting of 64 individual experiments with a time increment of 834 μs for the variable delays together with a fixed delay of 5 ms for a total maximum encoding period of 63 ms in the $[(90°)_{\phi_1}$–t_1–FD–$(45°)_{\phi_2}$–FD–t_2(acquire)]-sequence where t_1 is a variable delay, FD is a fixed delay and F_1 and F_2 are the two corresponding frequencies of interest after Fourier transformation of the data. The results when the data in the t_2 domain are truncated to 256 before zero-filling (a noise-reduction technique) are shown

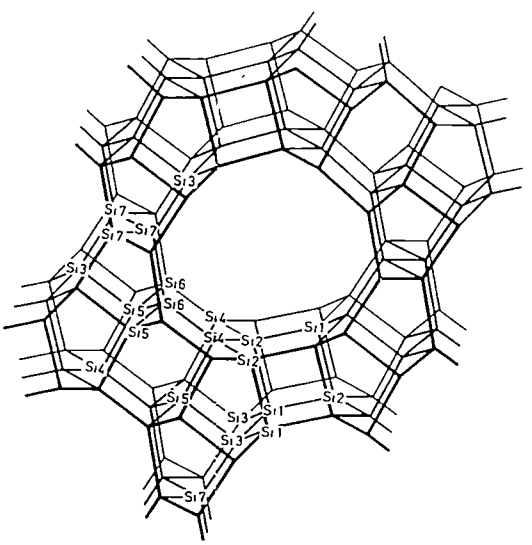

FIG. 1 Schematic representation of the zeolite ZSM-12 lattice framework. The seven crystallographically inequivalent tetrahedral-lattice sites are indicated by $Si_1, Si_2, \ldots, Si_7$ corresponding to T_1–T_7 in Table 1.

in Fig. 2. Clear connectivities are observed in the unsymmetrized plot; the truncation of the data in t_2 increases the signal intensity at the expense of resolution. The resonances may be assigned uniquely using only the expected connectivities presented in Table 1 as a guide (Fig. 2). Alternatively, T_5 may be unambiguously assigned as the resonance at $\delta = -112.3$ p.p.m. as it decreases significantly in intensity relative to the other signals if the recycle times used are too short, indicating that it has a much longer spin-lattice relaxation time. A major contribution to the relaxation mechanism is ^{29}Si dipolar interactions with molecular oxygen and T_5 is the only site that is not on the surface of a channel wall. From this assignment one can proceed to assign the others. Both of these approaches yield the labelling of the cross-peaks given in Fig. 2.

When the number of points in t_2 is increased to 450, the two-dimensional plot shows the same connectivities but with a lower signal-to-noise ratio (Fig. 3*a*). More interestingly, doublet splittings are observed for the cross-peaks in frequency F_2 (the limited resolution in F_1 precludes their observation). Figure 3*b* shows plots of rows from this two-dimensional experiment corresponding to the maxima in the diagonal peaks where the fine structure is clearly observable. The splittings are all 9–16 Hz, but these are approximate values only because the real digital resolution before zero-filling is only ~3 Hz per point and a power calculation has been used in the data processing. These data may be compared with the ^{29}Si-O-^{29}Si couplings observed[19] in alkaline silicate solutions enriched in ^{29}Si. The values range from 3 to 17 Hz with most couplings <10 Hz but many of the silicate species in solution have high concentrations of three-membered rings and do not relate directly to the local structures in zeolites. Silicon atoms in four- and five-membered rings in the species show couplings of the order of 10 Hz, approximately the values observed in the present work and we feel that the present data represent a direct observation of scalar ^{29}Si-O-^{29}Si couplings in the solid state.

The ability to obtain three-dimensional lattice connectivities in zeolites using natural-abundance samples greatly extends the potential of solid-state NMR techniques in this area and when combined with information from synchrotron X-ray powder diffraction should greatly assist in the solution of unknown structures. ^{29}Si COSY experiments such as these described above and also ^{29}Si INADEQUATE experiments (another pulse sequence that can establish connectivity patterns) have been applied successfully to a number of different zeolite structures (C.A.F., Y.F., H.G., H. Grondey and G.T.K., manuscript in preparation). □

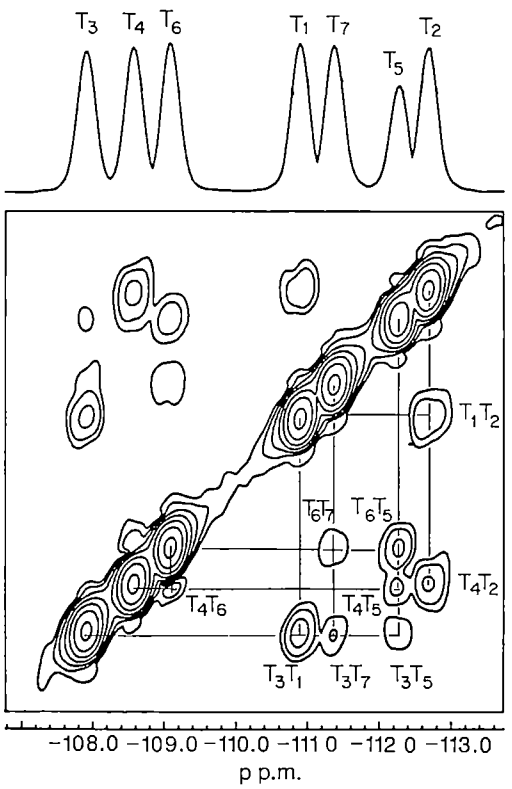

FIG. 2 Contour plot of a COSY experiment in ZSM-12 with the projection in the F_2 dimension shown on top. The temperature was 300 K and 64 experiments were carried out with 160 scans in each experiment. A sweep-width of 1,200 Hz, a fixed delay of 5 ms and 256 real data points were used (other channels are zero-filled) Sine-bell-squared apodization and magnitude calculation were used for the data processing

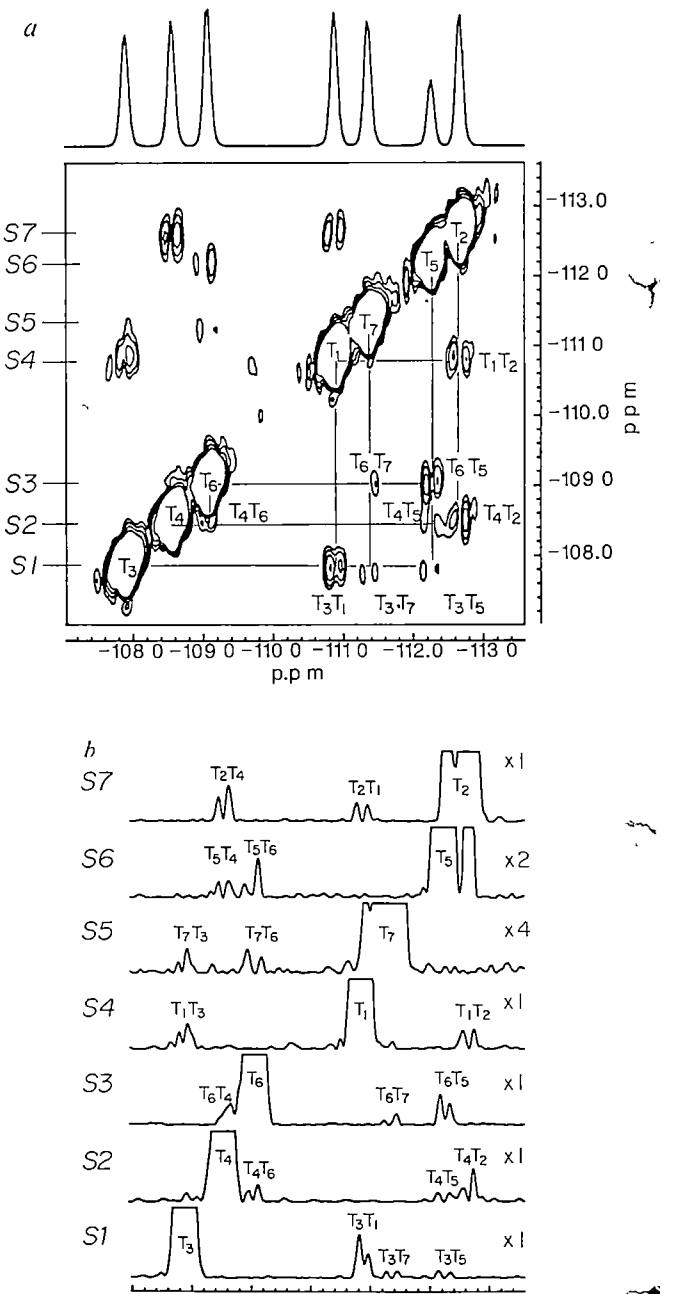

FIG. 3 *a*, Contour plot, with projection in F_2, of COSY experiment on ZSM-12. The same conditions as those in Fig 2 were used except that 80 scans were taken in each experiment. 450 real data points and power calculation were used in the data analysis. S1–S7 mark the rows of fixed frequency F_1 for the frequency F_2 spectra shown in *b*

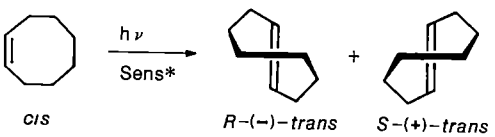
An optical yield that increases with temperature in a photochemically induced enantiomeric isomerization



'oshihisa Inoue, Taizo Yokoyama, Noritsugu Yamasaki & Akira Tai

asic Research Laboratory, Himeji Institute of Technology, 2167 Shosha, imeji, Hyogo 671-22, Japan

RANSFER of chirality and multiplication of chiral molecules are ey processes in the chemical and biochemical transformations of atural and synthetic compounds. For entropic reasons, structural nmobilization in enzymatic and catalytic processes and the use f low temperatures should generally enhance the optical yield preference for one enantiomer) in chiral reactions. Studies of the emperature dependence of optical yield in chemical and bio-emical processes have, however, been sporadic[1-10]. Here we port a systematic study of the temperature dependence of the hotosensitized enantiodifferentiating isomerization of a simple kene. We find that above a critical temperature, characteristic f the photosensitizer used, the optical yield increases with increas-ng temperature, apparently conflicting with the widely accepted iew that lower temperatures favour a higher optical yield. Thus oth enantiomers may be produced with high efficiency using a ngle chiral source. This implies that transfer and multiplication f chirality in natural systems, an important aspect of the develop-ent of prebiotic organic molecules, may be effected rather more mply than has hitherto been supposed.

Efficient photosensitized enantio-differentiation (producing ne enantiomer preferentially) has proved a difficult process to chieve. Despite considerable efforts over two decades[11-17], no iral photosensitization system has exceeded the optical yield f 7% reported in ref. 12. This has not been considered surprising ecause the steric interaction between sensitizer and substrate ot sufficiently strong and long-lived in most photoreactions. otochemical reactions are more amenable than thermal reac-ons to studies of the temperature dependence of the optical eld because in the latter case the reaction mechanism may ange with temperature.

We have demonstrated[15,16] that the (−)-menthylbenzoate- or isophthalate-sensitized *cis–trans* photoisomerization of *cis*-cyclooctene proceeds through a singlet exciplex and yields optically active *R*-(−)-*trans*-cyclooctene in 2–4% enantiomeric excess (ee) at room temperature.

Here we use (−)-menthyl and/or (−)-bornyl esters of benzoic, phthalic and pyromellitic acid as chiral sensitizers. To explore the temperature effect on the optical yield, the photosensitized enantio-differentiating isomerizations were performed at temperatures ranging from −83 to +50 °C. The solutions (300 ml of pentane, 0.2M *cis*-cyclooctene and 5–10 mM chiral sensitizer were contained in an annular quartz vessel that surrounded a 30-W mercury-resonance lamp fitted with a Vycor sleeve, which eliminates the 185-nm resonance line from the lamp. The 254-nm irradiations were carried out under an argon atmosphere, in a thermostated methanol bath (±0.5–1.0 °C), for a period sufficient to establish a photostationary state. After irradiation, the photolysate was extracted[16] with aqueous silver nitrate to isolate the *trans* isomer. The optical yields were determined by comparing the optical rotation of each product with the reported value $[\alpha]_D^{25} = -426°$ (*c* (grammes of sample per 100 ml of solvent) = 0.41, CH_2Cl_2)[18].

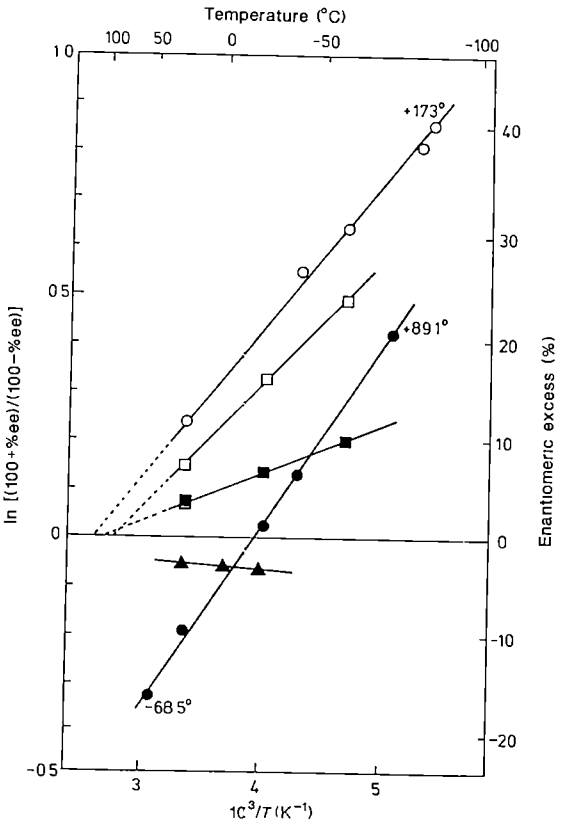


FIG 1 Temperature dependence of optical yield ln [(100 + %ee)/(100 − %ee)] as a function of reciprocal temperature in the enantio-differentiating photoisomerization of *cis*-cyclooctene sensitized by (−)-menthyl benzoate (▲), di-(−)-menthyl (■) and di-(−)-bornyl phthalate (□), and tetra-(−)-menthyl (●) and tetra-(−)-bornyl pyromellitate (○) in pentane solution, numbers in the plot show the optical rotations of the isolated *trans*-cyclooctene, $[\alpha]_D^{25}$ (*c* 1.0–3.4, CH_2Cl_2), accuracy in temperature ±0.5–1.0 °C; estimated error in %ee is ± 0.2%; reproducibility of %ee was tested with menthyl benzoate and dimenthyl phthalate at 25 °C—on the scale of this figure the points are almost superimposed.

In Fig. 1, we plot ln[(100+%ee)/(100−%ee)], where %ee has the same sign as the optical rotation, as a function of the reciprocal of irradiation temperature. In the case of menthyl benzoate sensitization, the optical yield decreases linearly with decreasing inverse irradiation temperature. The extrapolation to infinite temperature predicts a optical yield of virtually zero. A linear relationship is also obtained for reactions in which the sensitizers are the chiral phthalate and pyromellitate. Here, however, the zero-optical-yield line is crossed at finite temperatures (Fig. 1). In the case of methyl pyromellitate sensitization, the preferred chirality changes at −19 °C. For the other phthalates and pyromellitate sensitizers, similar changes are anticipated at 90–125 °C, just above the experimental temperature range. Below this critical temperature, which we tentatively name the iso-enantio-differentiating or simply the equipodal temperature T_0, the photoisomerization yields more *S*-(+)-*trans* isomer and the optical yield increases with decreasing temperature. The highest enantiomeric excess that we found was 40.6% for the tetrabornyl pyromellitate sensitization at −88 °C. Extrapolation predicts an enantiomeric excess of 100% at −246 and −243 °C for bornyl and methyl pyromellitate, respectively. Beyond T_0 the *R*-enantiomer predominates and the optical yield increases as the irradiation temperature increases, approaching the maximum enantiomeric excesses of 12–63% at infinite temperature.

This remarkable temperature dependence of the optical yield may be interpreted in terms of temperature-dependent populations of the diastereomeric exciplexes of the excited pyromellitates, which possess bulky substituents at the *ortho* positions, and the cyclooctene. We infer that the exciplex leading to *S*-(+)-configuration is predominant at low temperatures, whereas the other prevails at high temperatures and leads to an excess of *R*-(−)-configurations. We suggest that the steric interaction between adjacent bulky chiral alcohol moieties generates the diastereomeric exciplexes because only the *ortho* dicarboxylates like phthalate and pyromellitate exhibit this unusual temperature dependence, and because there is no indication of the ground-state diastereomeric conformers over the temperature range of −90 to +25 °C in the ^{1}H NMR (in fully deuterated acetone at 400 MHz) and circular dichroism spectra (in pentane) of tetra-(−)-menthyl pyromellitate. □

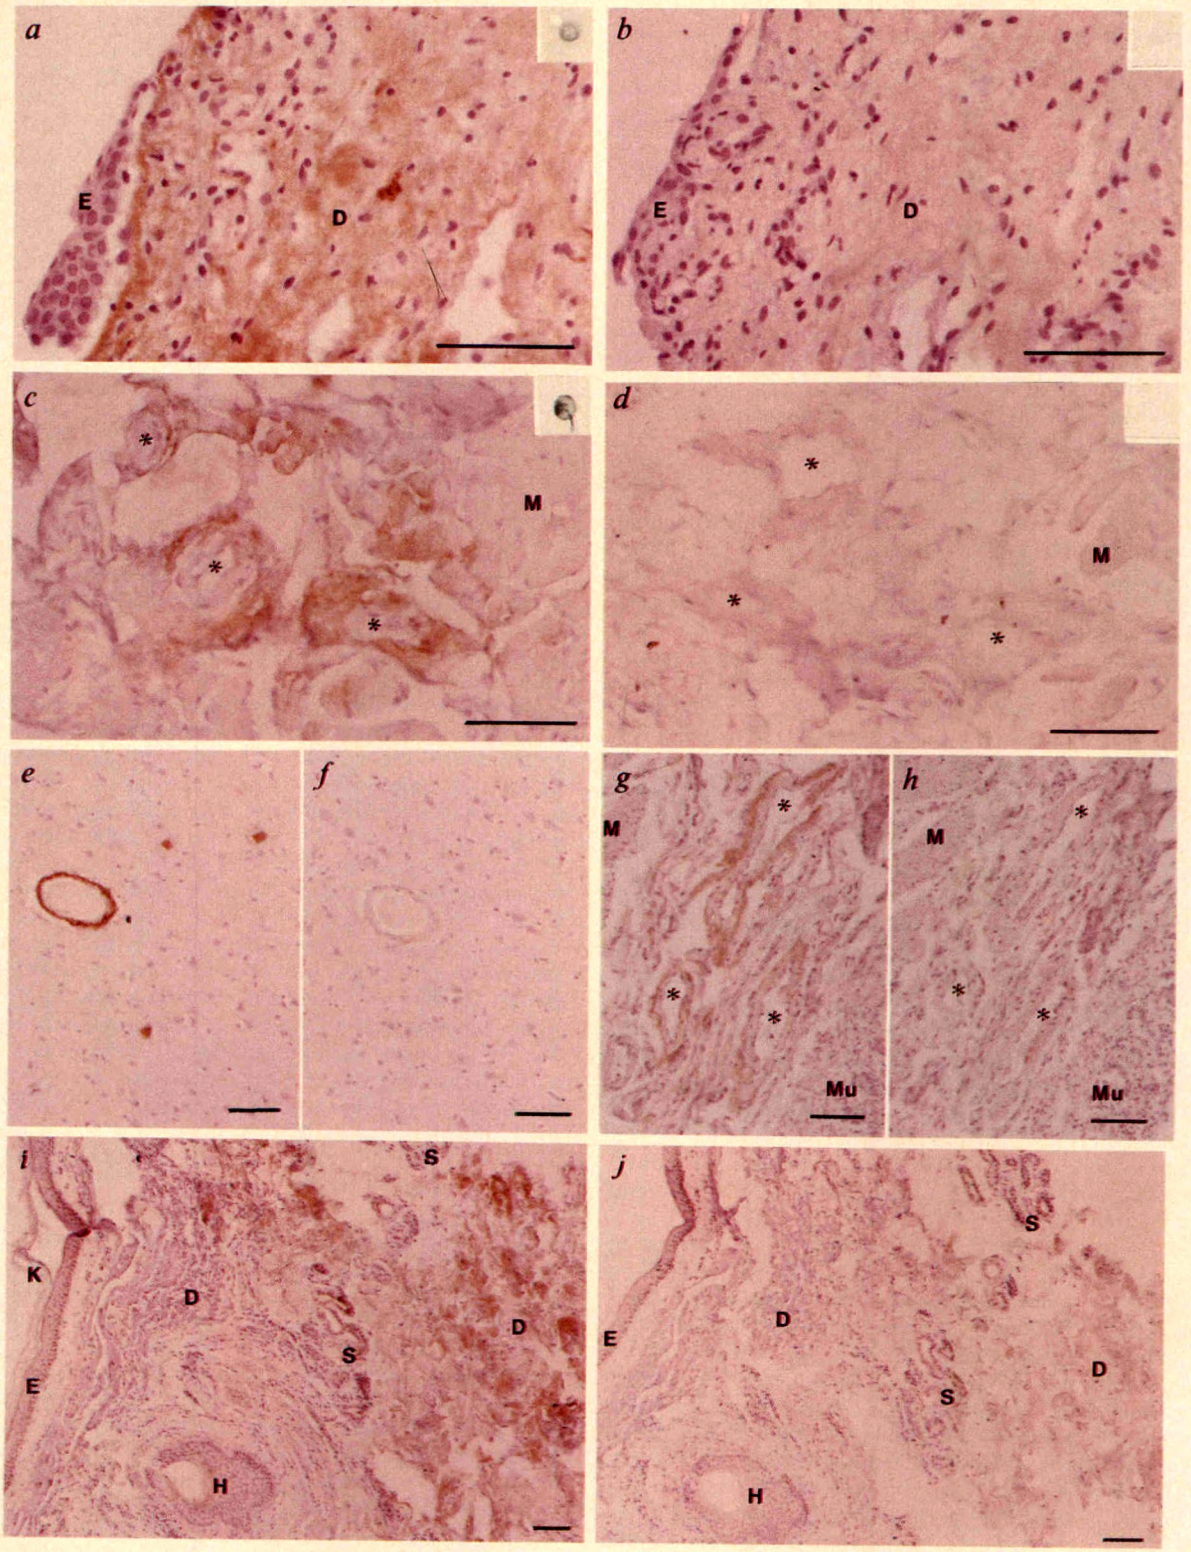
Amyloid β-protein deposition in tissues other than brain in Alzheimer's disease



Catharine L. Joachim, Hiroshi Mori & Dennis J. Selkoe

Department of Neurology (Neuroscience), Harvard Medical School and Center for Neurologic Diseases, Department of Medicine (Neurology), Brigham and Women's Hospital, Boston, Massachusetts 02115, USA

ALZHEIMER'S disease is the most common cause of progressive intellectual failure in aged humans. The filamentous brain lesions which define the disease occur within neurons (neurofibrillary tangles), in extracellular cerebral deposits (amyloid plaques) and in meningocerebral blood vessels (amyloid angiopathy)[1,2]. They are found in lesser numbers in the brains of virtually all old humans[1]. A protein with a relative molecular mass (M_r) of ~4,000, designated amyloid β-protein or amyloid A4 protein, is the subunit of the vascular and plaque amyloid filaments in individuals with Alzheimer's disease[3–5], normal ageing[6] and trisomy 21 (Down's syndrome)[7]. The amyloid β-protein is a small fragment of a membrane-associated glycoprotein[8–13], encoded by a gene on human chromosome 21 which is telomeric to a genetic defect that causes at least some cases of familial Alzheimer's disease[14,15]. Until now, the pathological lesions of the disease have been found only in the brain, although reports of phenotypic abnormalities in non-neural tissues[16–20] have suggested that Alzheimer's disease may be a widespread, systemic disorder. Here we report the detection of amyloid β-protein deposits in non-neural tissues and blood vessels of Alzheimer's disease patients, including skin, subcutaneous tissue and intestine. The protein was also present in non-neural tissues in a proportion of aged, normal subjects. Our findings indicate that a principal feature of the disease process is expressed subclinically in tissues other than brain. The occurrence of amyloid β-protein deposits in multiple tissues suggests that the protein may be produced locally in numerous organs or may, as in other human amyloidoses, be derived from a common circulating precursor. These observations affect the rationale for many experiments analysing the amyloid β-protein precursor and its messenger RNAs in Alzheimer's disease brain tissue and have major implications for the pathogenesis and treatment of the disease.

Amorphous, non-filamentous deposits of amyloid β-protein (βAP) without surrounding neuronal or glial alteration have recently been demonstrated in the brains of Alzheimer's disease patients and younger subjects with trisomy 21[21–24]. Because such 'preamyloid' deposits may represent a very early structural change in the brain, the question of the origin of amyloid deposits in Alzheimer's disease assumes added importance. We searched intensively for βAP deposits in tissues other than brain because of evidence that proteins present in cerebral plaques and vascular amyloid could derive in part from a circulating source[25–30]. We initially examined perianal skin taken at autopsy from a 78-year-old man with typical Alzheimer's disease and severe brain lesions. An antiserum to a synthetic peptide of residues 1–38 of βAP produced specific labelling of amorphous material deposited multifocally in the connective tissue and periarteriolar spaces of the dermis and subcutaneous tissue

FIG. 1 Immunocytochemical detection of βAP in non-neural tissues of Alzheimer's disease patients *a*, Section of non-keratinized perianal skin from a 78-year-old male with neuropathologically typical Alzheimer's disease (A85-196 in Table 2) reacted with control-absorbed antiserum A to native βAP purified from Alzheimer's cortex[5] E, epidermis, D, dermis. Inset, dot immunoblot of amyloid-plaque core fraction stained simultaneously. *b*, Adjacent section to *a* (and corresponding dot blot of plaques cores) reacted with antiserum A after absorption with plaque cores *c*, Subcutaneous tissue (case A85-196) reacted with antiserum Y to synthetic βAP_{1-38} Note circumferential periarteriolar locus of βAP-reactive material. Asterisks indicate lumens of arterioles, M, muscle fibres Inset, dot of peptide βAP_{1-3} stained simultaneously *d*, Adjacent section to *c* (and corresponding dot

reacted with antiserum Y after absorption with βAP_{1-38}. Absorption with an unrelated synthetic peptide ($\beta APP_{258-267}$; ref. 8) did not alter the staining. *e*, Alzheimer cerebral cortex reacted with antiserum A (control absorbed). Note characteristic staining of three amyloid plaque cores and amyloidotic arteriole. *f*, Adjacent section to *e* reacted with antiserum A absorbed with plaque cores. (Sections *e* and *f* were stained simultaneously with sections *i* and *j*.) *g*, Section of intestine from an 87-year-old female with typical Alzheimer's disease (A88–159 in Table 2) reacted with antiserum A (control absorbed). Note vascular staining in submucosal connective tissue. Asterisks indicate lumens of vessels; Mu, mucosa; M, smooth muscle fibres. Other βAP antisera produced a slightly different pattern of vessel wall staining. *h*, Adjacent section to *g* reacted with antiserum A absorbed with plaque cores. (Sections *g* and *h* were stained simultaneously with sections *a* and *b*). *i*, Biopsied skin (30-min formalin fixation) from an 85-year-old male with clinically typical Alzheimer's disease (X1330 in Table 2) reacted with antiserum A (control absorbed). Note strong βAP-immunoreactivity found multifocally in reticular dermis. E, epidermis; D, dermis; K, keratin; H, hair follicle; S, sweat glands. *j*, Adjacent section to *i* reacted with antiserum A absorbed with plaque cores. (Compare *i* and *j* with *e* and *f*.) Bars, 100 μm.

METHODS. Six-micron sections of formalin-fixed, paraffin-embedded tissues were stained with primary antibodies (1:250 for A or 1:500 for Y) for 12 h (4 °C) and reacted with biotinylated goat anti-rabbit IgG in an avidin/biotin peroxidase system (Vector Labs., Burlingame, California) according to standard protocols. Absorptions were performed by incubating (12 h, 4 °C) an antiserum with purified amyloid-plaque cores[5] (20 μg plaque-core protein per 1 μl antiserum) or with identically prepared control brain fractions (see text). For antiserum Y, synthetic βAP_{1-38} was used as absorbent.

which was inhibited by peptide. Adjacent sections of skin from this man, and skin from nine other Alzheimer patients were then examined with a panel of well-characterized antibodies to purified native βAP[5,31,32], synthetic βAP or unrelated proteins (Table 1). All four βAP antibodies that were tested produced selective, antigen-specific labelling of dermal and/or subcutaneous deposits (Fig. 1).

To determine the specificity of the immunolabelling, antigen-absorbed and 'control-absorbed' aliquots of each antiserum were reacted simultaneously with Alzheimer brain tissue and skin, and dot blots of the antigen (Fig. 1). For antiserum A, for example, partially purified SDS-extracted plaque cores[5] were used as the absorbent; a control absorption used an identically prepared fraction from aged normal brain tissue which contained the contaminating particles of plaque-core fractions (lipofuscin, collagen and microvessel fragments). In each such experiment, the plaque-core absorption significantly diminished or abolished the staining of plaque and vascular amyloid in Alzheimer's disease brain tissue, the dermal and subdermal amorphous deposits, and the antigen on dot blots, simultaneously (Fig. 1*b*, *d*, *f* and *j*). The control absorptions produced no change (Fig. 1*a*, *c*, *e* and *i*). Absorptions of unrelated antisera (P, DJ and G in Table 1) with the same plaque core fractions did not alter their immunoreactivities. Pre-immune sera, secondary antibodies alone and various antibodies (Table 1) to purified paired helical filaments[33], tau protein[32], glial fibrillary acidic protein[34], transthyretin (prealbumin) or the amyloid AA protein[35,36] all failed to label the skin deposits.

Because some βAP deposition in cerebral tissues and vessels occurs commonly during normal ageing, we examined samples of skin, subcutaneous tissue or intestine from 41 human subjects: 11 with Alzheimer's, 26 without Alzheimer's and 4 with Down's syndrome (Table 2). In all but four of the subjects, autopsies had established precise neuropathological diagnoses. Eight of the eleven cases of Alzheimer's disease showed definite βAP-reactive non-neural deposits and two showed slight, equivocal reactivity. By contrast, only 3 of 26 non-Alzheimer subjects showed definite non-neural βAP reactivity; all of these were ⩾77-years-old. Of four Down's syndrome skin samples, two were βAP-reactive and two were equivocal. In addition to autopsy-proven cases, we examined fresh punch biopsies of forearm skin from one Alzheimer subject and one normal subject (Table 2): the biopsy from the Alzheimer subject (age 85) showed specific βAP-staining (Fig. 1*i*, *j*), whereas that from the normal subject (age 64) did not.

Amyloid β-protein-immunoreactive deposits were located in the dermis in a patchy distribution beneath the epidermal/dermal junction, sometimes near small blood vessels or glandular elements. The stained material seemed to be localized extracellularly among connective tissue fibres in the reticular dermis (Fig. 1*a*, *i*). Some deposits were found circumferentially around small vessels, particularly arterioles. Most vessels and other skin structures (sweat and sebaceous glands, hair follicles, hair shafts, smooth muscle, epidermis and keratin) were unstained (Fig. 1*i*), further showing the specificity of the reaction. In subcutaneous tissue (Fig. 1*c*) and the submucosal tissue of the intestine (Fig. 1*g*), βAP-reactivity was found in and around microvessels and in perivascular connective tissue, apparently extracellular. Deposits of βAP were most easily visualized in the intestine, because they often occurred in a distinct vascular locus resembling that found in the brain and meninges. Almost all of the dermal deposits we observed had an amorphous, non-fibrillar appearance, perhaps analogous to the diffuse βAP deposits found in abundance in Alzheimer brains and the brains of some patients with hereditary cerebrovascular β-amyloidosis of Dutch type[37]. The non-neural deposits lost their reactivity with antibodies to synthetic βAP (Y in Table 1) when sections were pretreated with formic acid, a reagent that can enhance the staining of some brain βAP deposits[38]. The deposits in skin were not detected by the stains Congo red or thioflavin S.

TABLE 1 Summary of antibodies

Antiserum	Immunogen	Reference
A	βAP (M_r ~ 4,000) purified by HPLC from Alzheimer cortex	5, 32
C	βAP (M_r ~ 4,000) purified by HPLC from Alzheimer cortex	5, 32
F	βAP (M_r ~ 4,000) purified by HPLC from Alzheimer meninges	31
Y	Synthetic $βAP_{1-38}$ peptide	this report
P	Isolated paired helical filaments from Alzheimer cortex	33
DJ	Heat-stable microtubule-associated proteins (including tau) from human fetal brain	32
G	Glial fibrillary acidic protein	34
T	Human transthyretin	Calbiochem
AA	Isolated amyloid AA fibrils	35
Monoclonal antibody CB7	Isolated AA amyloid fibrils	36

References cited provide the characterization and typical dilutions used for each antiserum.

Our results provide the first demonstration that βAP, which is invariably and progressively deposited in the brain in Alzheimer's disease, is also deposited in extracerebral tissues. Four specific antibodies to native or synthetic βAP detect the tissue deposits before but not after βAP antigen absorption; staining of β-amyloid in the brain is simultaneously abolished. So far, antisera to proteins other than βAP have not labelled the non-neural deposits. Presumably, βAP was not detected in tissues other than brain previously because: (1) non-neural deposits (like many diffuse βAP deposits in the brain) are weakly reactive or not reactive with classical amyloid stains like Congo red and thioflavin; (2) the skin, which shows patchy, amorphous βAP immunoreactivity, has never been thought to be a likely site for β-amyloidosis in Alzheimer's disease, and (3) only antibodies to synthetic βAP, which detect non-neural deposits much less sensitively than our antisera to native βAP[5,31], were used. The presence of βAP in many of the skin sections we examined would have been difficult to establish if we had relied solely on synthetic βAP antibodies.

Our findings have several implications. First, βAP deposition believed to be a very early change in Alzheimer's disease and Down's syndrome brains[21–23], can occur in multiple sites throughout the body both in Alzheimer's and during normal ageing. This indicates that βAP deposition does not require preceding neuronal injury. Non-fibrillar forms of βAP are detectable in several tissues, but local cellular changes which are sufficient to cause clinical dysfunction are apparently associated only with some deposits in certain regions of the brain. Second, our findings may indicate multiple sites of βAP production by local cells in skin, intestine and other organs, including some cells in the brain. Alternatively, the presence of βAP in widespread non-neural tissues, particularly in and around arterioles, and its frequent perivascular deposition in meninges and the brain, are consistent with the hypothesis that βAP occurs in some circulating form and can reach tissues by means of the blood. No circulating form of βAP has yet been defined, and a mechanism whereby the hydrophobic, putatively transmembrane domain comprising βAP could circulate in the blood needs to be sought. Third, some of the phenotypic abnormalities previously reported in non-neural tissues of aged and Alzheimer's disease patients, particularly in skin-derived cells, could relate in part to the progressive deposition of βAP in these peripheral tissues. For example, a comparison of the properties of fibroblasts harvested from Alzheimer's skin that is either rich in or devoid of βAP deposits could be of interest

M, male; F, female AD, Alzheimer's disease; PD, Parkinson's disease; AA, amyloid angiopathy; CVA, cerebrovascular accident; SP, neocortical senile plaques; +, definite, specific staining; −, no staining; ±, slight or equivocal staining. ND, not determined. Skin samples (with subcutaneous tissue) were taken at autopsy, usually from the abdomen (except X1330 and X1362, which were 3-mm forearm punch biopsies). Skin samples from autopsy measured 14.3 ± 5.8 mm in length (mean ± s.d.) and 7.3 ± 5.0 mm in depth; sizes did not differ between Alzheimer's disease and controls. Each skin or colon sample was tested for specific βAP reactivity (see text and Fig. 1 legend) in 3–10 distinct immunostaining experiments carried out on different days. All stained sections (with simultaneous controls; see text) were examined and scored independently by each of the three investigators. In all cases but two (A89-14 and A88-347), all three investigators obtained the same score; the two exceptional cases each received scores of ±, ± and −.

* Approximate duration of disease (years).

† Typical neuropathological findings of both AD and PD.

A fourth implication of our findings is that the detection and quantitation of βAP in skin or another peripheral tissue might ultimately prove useful in confirming a clinical diagnosis of Alzheimer's disease and in following the course of the illness. Only a much larger prospective study of optimally preserved skin samples from patients with Alzheimer's disease and from aged normal subjects that have been biopsied and autopsied will clarify this issue. As expected, some aged normal humans were found to have βAP-reactive material in non-neural tissues, just as occurs in the brain. Amorphous deposits of cystatin C have recently been found in dermis and other non-neural tissues of Icelandic patients with hereditary cystatin C cerebrovascular amyloidosis[39]. Some apparent correlation between the degrees of skin- and cerebrovascular-cystatin C deposition has been observed in this late-onset, autosomal dominant amyloidosis of the brain (H. Blöndal, G. Guomundsson & E. Benedikz, personal communication).

Finally, if the perivascular βAP deposits in multiple tissues of Alzheimer's disease and aged, normal subjects arise from a circulating form of the molecule, then this could have potentially important implications for the design of novel therapeutic approaches to prevent the progressive deposition of β-amyloid in the brain. □

NMDA and non-NMDA receptors are co-localized at individual excitatory synapses in cultured rat hippocampus

John M. Bekkers & Charles F. Stevens

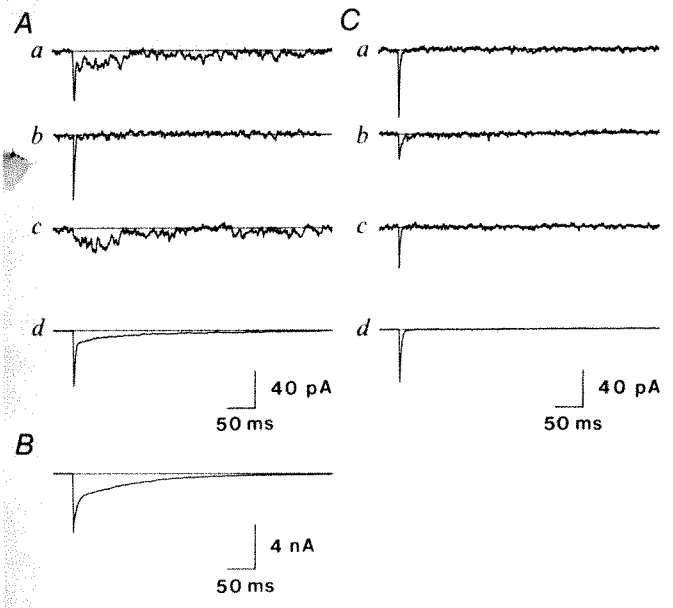
Section of Molecular Neurobiology, Howard Hughes Medical Institute, Yale University Medical School, 333 Cedar Street, New Haven, Connecticut 06510, USA

A CENTRAL assumption about long-term potentiation in the hippocampus is that the two classes of glutamate-receptor ion channel, the *N*-methyl-D-aspartate (NMDA) and the kainate/quisqualate (non-NMDA) subtypes, are co-localized at individual excitatory synapses[1,2]. This assumption is important because of the perceived interplay between NMDA and non-NMDA receptors in the induction and expression of long-term potentiation: the NMDA class, by virtue of its voltage-dependent channel block by magnesium[3,4] and calcium permeability[5,6], provides the trigger for the induction of long-term potentiation, whereas the actual enhancement of synaptic efficacy is thought to be provided by the non-NMDA class[7,9]. If both receptor subtypes are present at the one synapse, such cross-modulation could occur rapidly and locally through diffusible factors. By measuring miniature synaptic currents in cultured hippocampal neurons we show that the majority (~70%) of the excitatory synapses on a postsynaptic cell possess both kinds of receptor, although to different extents. Of the remaining excitatory synapses, ~20% contain only the non-NMDA subtype and the rest possess only NMDA receptors. This finding provides direct evidence for co-localization of glutamate-receptor subtypes at individual synapses, and also points to the possibility that long-term potentiation might be differentially expressed at each synapse according to the mix of receptor subtypes at that synapse.

When synaptic transmission in cultured hippocampal pyramidal neurons is blocked with tetrodotoxin (TTX), an ongoing spontaneous occurrence of small inward currents is observed (Fig. 1*A*, *C*; also ref. 10), which are similar to the spontaneous miniature endplate currents familiar in muscle fibres. These spontaneous events are thought to be due to the random release of quanta of neurotransmitter at individual excitatory synapses[10]. It is essential to our argument that this identification is correct, because we wish to infer from the properties of these miniature currents (which we have called 'minis') the distribution of glutamatergic receptors at single synaptic endings. In the study of these minis, we have examined four properties used to define neurotransmitter quanta: (1) small synaptic currents occur spontaneously when normal evoked synaptic transmission is blocked; (2) the minis have the same form and pharmacology as evoked currents; (3) the rate of occurrence is increased by the application of hypertonic solutions, even when normal release is blocked; and (4) the evoked synaptic currents arise by the summation of minis that occur with increased probability following stimulation.

First, in agreement with others[10], we find that not only the addition of TTX, which blocks the sodium spike, but also the chelation of external calcium or the blocking of calcium channels with cobalt, which prevents transmitter release evoked by voltage, fails to abolish the spontaneous occurrence of minis. This parallels results obtained in other preparations[11], where it is well established that spontaneous miniature currents arise at individual synaptic endings. Second, the linear addition of a large number of minis yields a current that has the same form as an evoked excitatory postsynaptic current (e.p.s.c.) (Fig. 1). In Fig. 1*A*, *a*–*c*, three representative minis are shown with their rising edges aligned; the average of 58 such traces captured randomly from one cell is shown in Fig. 1*A*, *d*. This average is very similar in shape to the trace in Fig. 1*B*, which is a single record taken from another voltage-clamped cell in which an e.p.s.c. was elicited by firing an action potential in a nearby pyramidal neuron (note different vertical scale bar).

In addition to the fact that minis and e.p.s.cs have the same form, components of the minis could, like the corresponding



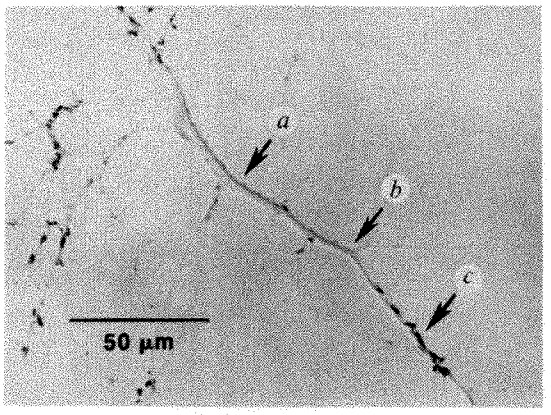


FIG. 1 Spontaneous minis sum to produce a current like an evoked e.p.s.c., and have a D-APV-sensitive slow component. All panels show the current recorded from a cultured hippocampal pyramidal cell voltage clamped at −60 mV. *A*: *a–c*, Representative spontaneous minis from one cell with their rising edges aligned; *d*, average of 58 minis, including those in *a–c*, from one cell. *B*, Excitatory postsynaptic current (e.p.s.c.) recorded in a cell in response to the firing of an action potential in another cell in the same culture dish. *C*: *a–c*, Spontaneous minis from the same cell as *A*, after bath perfusion of 100 μM D-APV; *d*, average of 32 minis, including those in *a–c*. METHODS. Hippocampal pyramidal cells were prepared from newborn rats as described[6] and used after 7–18 days in culture. Currents were recorded by a patch electrode in the whole-cell mode; in panel *B* a second whole-cell electrode was used to fire the presynaptic cell. The bath solution normally contained (mM): NaCl (137), KCl (5), $CaCl_2$ (3), glucose (10), HEPES (5), pH 7.3, osmolarity adjusted to 310 mOsm with sorbitol, to which was added 1 μM glycine, 1 μM strychnine, 100 μM picrotoxin and 1 μM TTX (no TTX in *B*). In some experiments the $CaCl_2$ was replaced by 2 mM $CoCl_2$. External solution changes were effected by perfusing >10 times the chamber volume. The pipette solution contained (mM): CsCl (150), CsBAPTA (5) (1,2-bis(*o*-aminophenoxy) ethane-*N,N,N′,N′*-tetraacetic acid), HEPES (10), pH 7.2; in *B*, the presynaptic pipette contained the same solution, except that K^+ replaced Cs^+ so that the action potential repolarized rapidly. Experiments were at room temperature (23–25 °C). Sources of chemicals: D-APV (Cambridge Research Biochemicals), CNQX (Tocris Neuramin), CsBAPTA and KBAPTA (Molecular Probes). Salts for bath solutions were from Alfa (Puratronic).

components of synpatic currents, be differentially blocked by specific glutamate-receptor antagonists. All of the recordings in Fig. 1 were made in a bath solution nominally without magnesium to optimize the detection of NMDA currents. The slow component in Fig. 1*A*, *d* and Fig. 1*B*, which by its kinetics indicates NMDA current[12], was abolished by 100 μM D-APV (D-2-amino-5-phosphonovaleric acid), a specific blocker of NMDA channels[13]. This is illustrated in Fig. 1*C*, in which representative individual traces (*a–c*) and the average of 32 such traces (*d*) are shown, taken from the same cell as in Fig. 1*A* after perfusion with D-APV. Bath perfusion with a high magnesium concentration instead of D-APV gave a similar result, whereas perfusion with 10 μM CNQX (6-cyano-2,3-dihydroxy-7-nitroquinoxaline), which blocks non-NMDA (K/Q) channels[14], abolished the fast component of the spontaneous minis but did not affect the slow, noisy component (data not shown).

Third, we studied the effect of applying hypertonic solutions locally, which increases the frequency of spontaneous miniature endplate potentials (m.e.p.ps) at the neuromuscular junction by inducing asynchronous release of presynaptic vesicles[15], even when normal transmitter release has been blocked. Results are

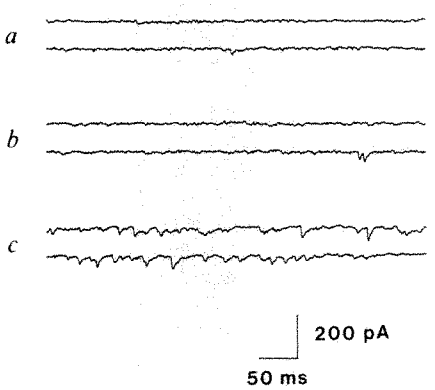

FIG. 2 Minis evoked by hypertonic solution are the same as spontaneous minis and can be evoked only where synapses are located. Top, a cultured pyramidal cell stained for synapsin I (dark granules) and showing three locations (*a, b, c*) where hypertonic solution was locally applied. Bottom, representative currents recorded while voltage clamping the soma at −60 mV and applying hypertonic solution at each of *a, b, c*. Altogether, 48 dendritic locations were studied in 9 different cells, for 43 of which the location of the hypertonic solution application could be unambiguously correlated with the results of the synapsin I stain. Of these, 30 locations contained stained boutons, and minis (excitatory and/or inhibitory) could be evoked at these locations by hypertonic solution. In none of the 13 locations without stained boutons could mini activity be evoked. The probability of a chance association between staining and activity for this number of trials is 2×10^{-5} (sign test).
METHODS. Electrophysiology and solutions as decribed in Fig. 1 legend, except that picrotoxin was omitted. Hypertonic solution (bath solution to which sucrose was added at 0.5 M) was applied in 300 ms bursts with a buffer pipette and removed by a nearby suction pipette (diameter ~10 μm) to restrict flow to a plume ~15 μm wide. The cell was afterwards fixed in 4% formaldehyde and incubated overnight in synapsin I antibody diluted 1:100 in PBS; binding was localized with peroxidase.

shown in Fig. 2. Bath solution, made hypertonic by addition of sucrose, was applied locally using a puffer pipette at three points (*a, b, c*) on the dendrite of a pyramidal cell and the response recorded while voltage-clamping the soma. Application at point *c*, but not at *a* or *b*, resulted in a burst of small inward currents. These minis are evoked locally, 150 μm from the recording site on the cell body, a conclusion based on the observations that activity is produced by application of hypertonic solution only to certain locations, and that the mini currents are filtered by the dendritic cable to an extent which is dependent on the position at which the solution is applied[16]. The currents evoked by hypertonic solution are similar in size, kinetics, pharmacology and ionic selectivity to spontaneously occurring minis, similar to those illustrated in Fig. 1, although the particular currents shown in Fig. 2 appear different as a result of cable filtering.

The cell shown in Fig. 2 was then labelled using an antibody

to synapsin I, a protein associated with presynaptic vesicles and therefore a specific marker for synapses[17]. This histochemical marker revealed that the small inward currents could be evoked only at places where synapses are present (location *c*, Fig. 2). These results suggest that both spontaneous and hypertonic-solution-evoked minis arise from sporadic release of transmitter at individual synaptic endings.

Finally, we performed a quantal analysis to determine whether the statistical properties of the spontaneous minis were consistent with their being the basis of 'macroscopic' evoked synaptic currents. Examples of such currents are shown in Fig. 3 (insets); these are consecutive records in which an action potential was fired in a presynaptic cell and the postsynaptic response measured under voltage clamp. Each postsynaptic current was integrated to yield charge, which is a measure of the quantity of neurotransmitter released that is insensitive to jitter in the time at which individual quanta are released. Charge histograms were constructed from 62–455 consecutive records from the same cell pair in each of three different calcium concentrations (Fig. 3*b–d*). A charge histogram was also constructed for spontaneous minis recorded in the postsynaptic cell (Fig. 3*a*).

It is important to note the broadness of the distribution of mini sizes. In recordings from spontaneously occurring minis *in vivo*, we cannot tell how much of this size variation is an inherent property of the minis, and how much arises through cable distortion of synaptic currents produced at various locations over the dendritic tree. We have determined, however, that the spread in mini sizes obtained with sucrose applied locally at the soma, for which cable distortion is minimal, is the same as that shown in Fig. 3*a*. The wide range in mini size thus reflects inherent variability in individual events, at least in cultured neurons, and is not a consequence of cable attenuation.

The goal of our quantal analysis was to test whether the distribution of mini sizes (Fig. 3*a*), together with the assumption that the probability of occurrence of a single mini is binomially distributed, could predict the shapes of the evoked histograms (Fig. 3*b–d*). The fitting procedure was complicated by the fact that the distribution of mini sizes possessed a variance σ^2 that was significant compared with the variance, var (q), of the evoked distributions. Assuming independence and linear addition of the minis, it follows from elementary probability theory that $\bar{q} = \mu\bar{k}$, and var $(q) = \mu^2 s^2 + \bar{k}\sigma^2$, where $\bar{q}$ is the measured mean of the evoked distributions, μ is the measured mean of the spontaneous minis, $\bar{k} = Np$ and $s^2 = Np(1-p)$, where N and p are the usual binomial parameters. The two equations can thus be solved for the two unknowns N and p. This was done for each of the histograms in Fig. 3*b–d* (see figure legend for details) and the superimposed smooth curves are the calculated distributions. Note that the broadness of the underlying mini distribution acts to obliterate the discrete quantal peaks often observed in other preparations[18]. Excellent fits were also obtained for four other cell pairs in various calcium concentrations. These results show that evoked synaptic currents vary in amplitude in the way that would be expected if they were composed of the sum of probabilistically occurring minis.

Because our minis possess the four classes of characteristics that are used to define quantal events, we conclude that each mini in Fig. 1 reflects activation of receptors at a single excitatory synapse. Interestingly, some minis consisted entirely of slow NMDA-type responses (Fig. 1*A*, *c*), some of fast, non-NMDA type responses (Fig. 1*A*, *b*) and some of mixtures of both (Fig. 1*A*, *a*). This observation is quantified in Fig. 4, which shows superimposed histograms of the ratio slow-current/fast-current amplitude for mini e.p.s.cs recorded in the absence (bars) and presence (dotted line) of 100 μM D-APV. With D-APV the histogram is centred on the baseline—currents possess only the fast conductance—whereas without D-APV there is a distribution of mini e.p.s.cs with varying proportions of slow (NMDA) and fast (non-NMDA) currents. In this case ~110 out of 160 mini currents (66%) contained a mixture of NMDA and non-NMDA components and 16 (10%; far right bar) seemed to be pure NMDA currents, although it is probable that a number of these were missed owing to their small size and noisiness. Similar results were obtained in three other cells.

Assuming that the conductance of a single NMDA channel in these cells is the same at the synapse as at the soma (50 pS, ref. 6), at most ~8 NMDA-type channels are open in Fig. 1*A*, *a* and *c*. Single-channel fluctuations should be apparent in such

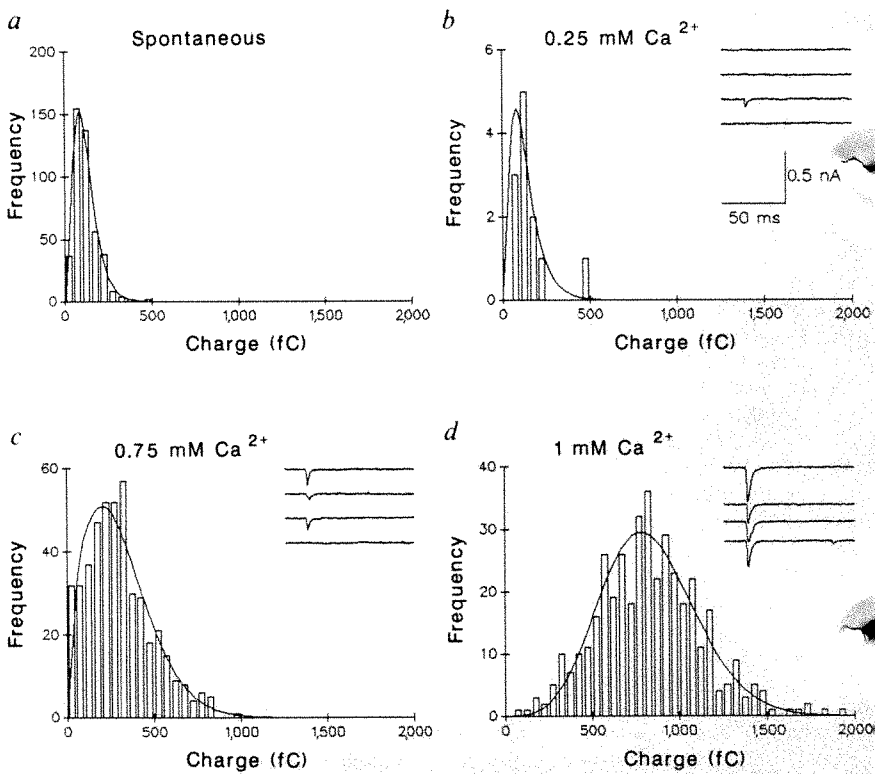

FIG. 3 Quantal analysis of the fast component of evoked e.p.s.cs from an isolated pair of pyramidal cells. The figure shows histograms of charge carried by spontaneous minis (*a*) and by evoked e.p.s.cs measured in the same postsynaptic cell in three different calcium concentrations (*b–d*). Insets show typical consecutive postsynaptic current traces, stimulated at 0.67 Hz; calibration bars in *b* apply to all insets.

METHODS. As in Fig. 1, except the bath omitted TTX and contained 10 mM Mg^{2+}, and both pre- and postsynaptic electrodes contained KCl. The postsynaptic cell was voltage-clamped at −60 mV, which is near the resting potential for these solutions. The smooth curve in *a* is a semi-empirical function (unpublished data) which was fitted by eye. Values for N and p were calculated as described in the text for each evoked histogram. The mean of these N values was found to be 14 ± 5 (±s.d., $n = 3$) and N was constrained to this mean for all calcium concentrations. The predicted distribution was then calculated using a convolution technique that takes into account the mini distribution in panel *a*, and the value of p was adjusted slightly for each panel until a good visual fit was obtained. The smooth curves in *b–d* show predicted distributions for the following values of p: 0.02 (0.25 Ca^{2+}), 0.18 (0.75 Ca^{2+}), 0.56 (1 Ca^{2+}). The observed and predicted numbers of failures were, respectively: 50 and 47 (0.25 Ca^{2+}), 24 and 28 (0.74 Ca^{2+}), 0 and 0 (1 Ca^{2+}).

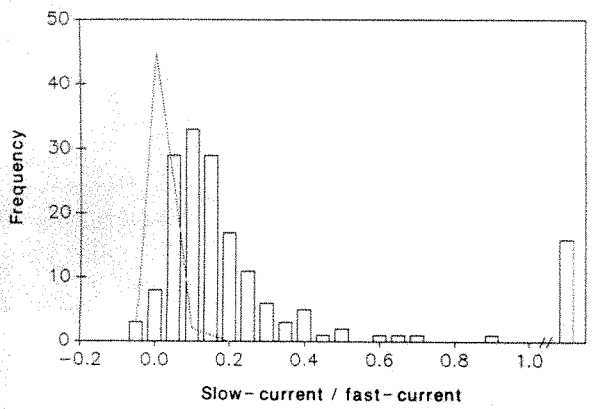

FIG. 4 Histograms showing the distribution of size of the slow, D-APV-sensitive current relative to the size of the fast current in spontaneous mini e.p.s.cs. Bars (167 events measured), without D-APV; dotted line (76 events measured), with D-APV; all taken from the same cell as shown in Fig. 1*A* and *C*. The fast amplitude was measured at the peak of the spike occurring 1–2 ms after the foot of the mini, at which time the NMDA current has only just begun to turn on (unpublished data); the slow amplitude was measured by averaging over a 10 ms window starting 10 ms after the peak of the fast spike. The bar to the far right represents 16 minis that seemed to consist purely of slow component.

a small population, and this accords with the noisy appearance of the traces. With a conductance for the non-NMDA channels of 10 pS (ref. 6), the fast component of the minis in Fig. 1*A*, *a* and *b*, would require ~110 such channels to be open at the peak, although a recent suggestion[19] that the fast component arises from channels with a 35 pS conductance would imply that only about 30 channels are open. The above channel numbers might be up to twice as large at some synapses, judging by the spread in mini amplitudes from synapse to synapse.

Typically, about 70% of the mini e.p.s.cs we measured possessed both fast and slow components. Assuming that the probability of occurrence of a mini was the same at all synapses, irrespective of the mix of receptor subtypes at that synapse, about 30% of the excitatory synapses on our cells contained only NMDA or only non-NMDA-type receptor-channels. It is not known if a similar situation arises in hippocampal slices, where long-term potentiation has been most actively studied. It is interesting to consider, however, whether long-term potentiation could be induced at a synapse that does not contain both subtypes. This would require the study of long-term potentiation at only a few synapses, rather than by the usual means of averaging the contributions of many synapses.

In addition to showing that NMDA and non-NMDA channel subtypes are co-localized at individual synapses, we have also found that the statistical model for quantal release first developed for the neuromuscular junction[20] also seems adequate for excitatory synapses in the hippocampus. The analysis is complicated, however, by the fact that individual quanta vary considerably in size. We anticipate that this description of transmitter release will be useful in distinguishing between pre- and postsynaptic mechanisms of long-term potentiation. □

Glucose-inhibition of glucagon secretion involves activation of $GABA_A$-receptor chloride channels

THE endocrine part of the pancreas plays a central role in blood-glucose regulation. It is well established that an elevation of glucose concentration reduces secretion of the hyperglycaemia-associated hormone glucagon from pancreatic α_2 cells. The mechanisms involved, however, remain unknown. Electrophysiological studies have demonstrated that α_2 cells generate Ca^{2+}-dependent action potentials. The frequency of these action potentials, which increases under conditions that stimulate glucagon release, is not affected by glucose or insulin[1]. The inhibitory neurotransmitter γ-aminobutyric acid (GABA) is present in the endocrine part of the pancreas at concentrations comparable to those encountered in the central nervous system[2], and co-localizes with insulin in pancreatic β cells[3]. We now describe a mechanism whereby GABA, co-secreted with insulin from β cells, may mediate part of the inhibitory action of glucose on glucagon secretion by activating $GABA_A$-receptor Cl^- channels in α_2 cells. These observations provide a model for feedback regulation of glucagon release, which may be of significance for the understanding of the hypersecretion of glucagon frequently associated with diabetes[4].

Immunostaining of pancreatic islet cells for $GABA_A$-receptor revealed a positive reaction in glucagon-containing α_2 cells and somatostatin-containing α_1 cells (Fig. 1*a*, *d*), but not in β cells. The α_1 cells were generally smaller than the α_2 cells and were characterized by an irregular morphology with projecting cellular processes. Such cells were excluded from electrophysiological recordings in favour of round cells with large diameters corresponding to α_2 cells (20–25 μm; cell capacitance 10–20 pF). The existence of $GABA_A$ receptors on α_1 cells is not surprising in view of its reported inhibitory effect on somatostatin secretion[5].

The top trace of Fig. 1*e* shows a membrane-potential recording from a single α_2 cell. The cell generates spontaneous overshooting Ca^{2+}-dependent action potentials from −60 mV. Application of 100 μM GABA results in a hyperpolarization of ~15 mV and the cessation of spiking activity. Withdrawal of GABA leads to depolarization and the reappearance of action

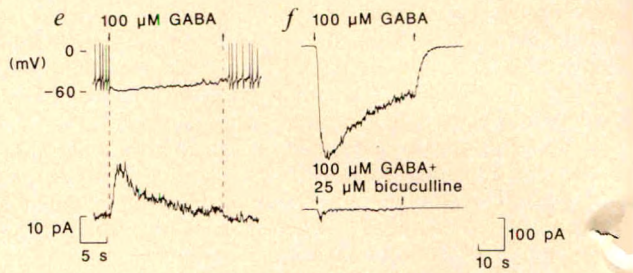

FIG. 1 *a*, Photomicrograph illustrating glucagon immunoreactive guinea-pig pancreatic islet α_2 cells. *b*, Photomicrograph demonstrating that a number of the glucagon immunoreactive cells in *a*, were also immunoreactive against $GABA_A$-receptor antibodies (arrows). Somatostatin immunoreactive guinea-pig pancreatic α_1 cells (*c*) were also immunoreactive against $GABA_A$-receptor antibodies (*d*). Bar, 25 μm. *e*, Top, membrane potential recording from a guinea-pig α_2 cell. Application of 100 μM GABA (indicated by the arrows and the vertical dashed lines) results in a hyperpolarization and the cessation of spiking activity; bottom, whole-cell voltage-clamp current record from same cell. Cell was clamped at −40 mV. Outward current was activated by GABA. Pipette was filled with solution containing low $[Cl^-]_i$. *f*, Top, current response evoked by GABA. With the solutions used, $[Cl^-]$ is about the same on both sides of the membrane. At negative membrane potentials, chloride ions will therefore leave the cell, giving rise to an inward current. With low $[Cl^-]_i$, currents will be outward as in *e*. Bottom, suppression of response to 100 μM GABA after inclusion of 25 μM bicuculline (dissolved in dimethyl sulphoxide; final concentration 0.1%).

METHODS. Guinea-pig pancreatic islet cells were prepared and cultured for 1–3 days as previously described[1]. The cells, which attach spontaneously to the bottom of the tissue-culture dishes, were fixed for ~5 min with PLP-fixative[16] containing 0.01 M periodate, 0.075 M D-L-lysine and 2% paraformaldehyde in 0.1 M phosphate buffer. For storage, the fixative was removed and replaced with normal extracellular solution. The cells were pretreated with 0.2% Triton X-100 for 1 h and then incubated for 3 days in rabbit anti-glucagon (Novo, Sweden), rabbit anti-somatostatin (Bio-Bol, Sweden) antibodies diluted 1:3,000 and 1:1,000, respectively, or in 100% mouse hybridoma (bd-17) supernatant—an antibody against the β-subunit of the $GABA_A$ receptor. The preparation and characteristics of the antibody have previously been described[17,18]. The β-subunit protein, recognized by bd-17, is part of the $GABA_A$-receptor Cl^--channel complex. When coexpressed with the α-subunit protein in *Xenopus* oocytes, GABA-gated chloride channels are formed[19]. To visualize the antigen-antibody complexes, the cells were incubated in fluorescein-isothiocyanate labelled porcine anti-rabbit antibodies (Dakopatts, Copenhagen) diluted 1:100 in PBS medium followed by an incubation for 30 min in the immunoglobulin fraction of rabbit normal serum (Dakopatts) diluted 1:10 in PBS. Finally, the cells were incubated for 1 h in rhodamine-conjugated rabbit anti-mouse antibodies (Dakopatts) diluted 1:100. The whole-cell configuration of the patch-clamp technique[20] was used to record membrane potentials and currents. Pancreatic islets were isolated from guinea-pigs by collagenase digestion. The isolated islets were dissociated into single cells using trypsin, plated on coverslips and maintained in tissue-culture (RPMI 1640 supplemented with 10% v/v FCS, with antibiotics) for up to one week. The α_2 cells were identified on the basis of their large size (diameter 20–30 μm; cell capacitance >10 pF) as previously described[1]. Immunohistochemistry confirmed that the majority of large cells were glucagon-containing α_2 cells. Throughout the electrophysiological experiments, the cells were immersed in an extracellular solution containing (in mM): NaCl, 138; KCl, 5.6; $MgCl_2$, 1.2; $CaCl_2$, 2.6; HEPES-NaOH (pH 7.4), 5. The pipette-filling solution in the membrane-potential recording experiment *e* was composed of (in mM): K-glutamate, 125; $MgCl_2$, 1; EGTA, 10; MgATP, 3; HEPES-HCl, 5 (pH 7.15); total $[Cl^-]_i$ = 4.5 mM. In *f*, the pipette was filled with a medium containing (in mM): N-methyl-D-glucamine (NMG), 150; HCl, 110; EGTA, 10; $MgCl_2$, 1; MgATP, 3; HEPES-HCl, 5 (pH 7.15); total $[Cl^-]_i$ = 120 mM. An EPC7 (List Electronic, Darmstadt, FRG) patch-clamp amplifier was used for the electrophysiological recordings. Pipettes were pulled from borosilicate or aluminosilicate glass (Hilgenberg, Malsfeld, FRG) and had resistances of 4–10 MΩ. The current and voltage signals were recorded on magnetic tape using a Racal 4 Store FM tape recorder.

potentials. Recordings of spiking activity from cell-attached patches on arginine-stimulated cells revealed a similar inhibition by GABA (data not shown). The bottom trace shows a whole-cell voltage-clamp current record from the same cell. It was observed that the inhibition of the electrical activity is coincident with the activation of an outward current. In Fig. 1*f*, we show that the current elicited by GABA is completely and reversibly blocked by 25 μM of the $GABA_A$-receptor antagonist bicuculline. Similar effects were obtained with 25 μM picrotoxin (data not shown). The currents elicited by GABA depend on the intracellular Cl^- concentration, as shown in Fig. 2*a*. The reversal potential was shifted from -8 ± 2 mV ($n = 3$) when recorded with an intracellular Cl^--concentration ($[Cl^-]_i$) of 120 mM, to -45 ± 5 mV ($n = 3$), when recorded with a $[Cl^-]_i$ of 20 mM. This shift of 37 mV is in reasonable agreement with that expected from the Nernst equation for a sixfold change of $[Cl^-]_i$. Figure 2*b* shows the single-channel events that produce the whole-cell currents evoked by GABA, panel (i). The current voltage (i-V) relationships recorded with low and high $[Cl^-]_i$ for the most common conductance state are shown in panel (ii). The single-channel conductances were 29 ± 2 pS ($n = 6$) for the inward current and 18 ± 1 pS ($n = 6$) for the outward currents when recorded with high $[Cl^-]_i$ (120 mM). The latter value corresponds to the 17 ± 1 pS ($n = 4$) obtained when recording outward currents with low $[Cl^-]_i$. The single-channel currents could be fitted to the constant field current equation in the voltage range −80 to +60 mV. Assuming an activity constant of 0.75 for Cl^- (ref. 6), we obtained estimates of P_{Cl} of $(6.2 \pm 0.2) \times 10^{-13}$ cm^3 s^{-1} ($n = 5$) and $(6.0 \pm 0.1) \times 10^{-13}$ cm^3 s^{-1} ($n = 4$) for high and low $[Cl^-]_i$, respectively. From the observations in Figs 1 and 2 it can be concluded that the currents elicited by GABA in the α_2 cells are carried by $GABA_A$-receptor Cl^- channels similar to those described in other cell types[6-9].

The concentration dependence of GABA-evoked currents is shown in Figure 3*a*. The current amplitude was extremely variable and, for a pulse of 100 μM GABA, ranged between a few to several hundred picoamperes in cells of a similar size. Figure 3*b* shows a dose-response curve. At concentrations ≥30 μM, currents desensitize and true peak current amplitudes were estimated by extrapolation of the decaying part of the current response to time zero. The sigmoidal curve was obtained by approximating the data to the equation $I(C)/I_{max} = C^n/(C^n + K_a^n)$ (equation 1), where $I(C)$ is the Cl^- current elicited by a GABA concentration of C, I_{max} the maximal current amplitude, n the Hill factor and K_a the concentration of GABA eliciting a half-maximal current response. In six experiments, average values of K_a and n were 40 ± 6 μM and 2.0 ± 0.3, respectively. The latter value is similar to that reported in other cells[7,10,11] and suggests that the binding of two molecules of GABA is required for a channel opening in the α_2 cell. The currents evoked by 30 μM GABA were approximately doubled in the presence of 10 μM of the benzodiazepine diazepam, or after replacement of GABA by muscimol (data not shown), as expected for $GABA_A$ receptor Cl^- currents.

The effects of GABA and bicuculline on glucagon secretion from isolated islets is shown in Table 1. Arginine enhanced glucagon secretion 1.6-fold. Addition of 100 μM GABA counteracted this effect and reduced the arginine-stimulated release by 70%. This effect of GABA was abolished by addition of 100 μM bicuculline. Inhibition of glucagon secretion was also observed when glucose was increased to 16.7 mM in the absence of arginine. This effect was also counteracted (down 50%) by bicuculline. This suggests that $GABA_A$-receptor Cl^--channels are indeed involved in glucose regulation of glucagon release and that the interstitial GABA concentration increases to physiologically active levels during stimulation of insulin secretion. We acknowledge that although we are able to detect GABA being released from the pancreatic islets, we have so far failed to demonstrate an enhancement by glucose. It should be emphasized, however, that glucose has been reported to increase not only the release of insulin, but also that of GABA[12]. The failure of bicuculline to completely suppress the inhibitory effect of supraphysiological glucose concentrations suggests that part of this inhibition results from a mechanism not involving $GABA_A$ receptor activation[13,14]. Somatostatin is a potent inhibitor of glucagon release. As α_1 cells are equipped with $GABA_A$ receptors, it is important to exclude that the action of GABA on glucagon release is secondary to a change in the

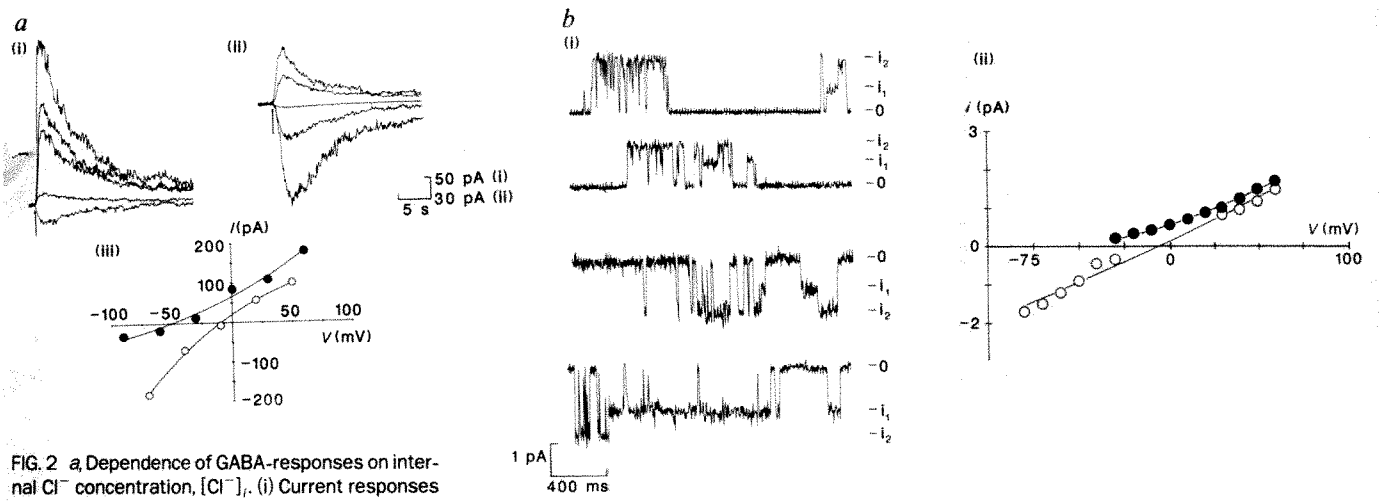

FIG. 2 *a*, Dependence of GABA-responses on internal Cl^- concentration, $[Cl^-]_i$. (i) Current responses elicited by 100 μM GABA at different membrane potentials using a pipette filled with low $[Cl^-]_i$. (ii), Current responses elicited by 100 μM GABA at different membrane potentials using a pipette with high $[Cl^-]_i$. (iii) Whole cell current (I)-voltage (V) relationship for the peak currents in (i) and (ii). The curves were drawn according to the function $I(V) = A(V - V_r) \exp[B(V - V_r)]$ where $I(V)$ is the peak current at a voltage V and V_r is the reversal potential. The values of V_r, A and B were derived from an iterative least-squares routine. *b*, (i) Single-channel activity evoked by 10 μM GABA recorded from an outside-out patch at membrane potentials (from top to bottom) of +70, +50, −50 and −70 mV recorded with high $[Cl^-]_i$. At least two conductance levels are seen (marked i_1 and i_2). (ii) Single GABA-receptor channel i-V relationships of the most common conductance state. Currents were recorded with $[Cl^-]_i$ of 20 mM (solid circle) or 120 mM (open circle). The solid lines represent fits to the constant field current equation where P_{Cl} equals 6×10^{-13} cm^3 s^{-1} ($[Cl^-]_i = 20$ mM; solid circle) and 5.7×10^{-13} cm^3 s^{-1} ($[Cl^-]_i = 120$ mM; open circle).

METHODS. The high-$[Cl^-]_i$-solution was the NMG-medium specified in the legend to Fig. 1. The low-$[Cl^-]_i$-solution contained (in mM): NaCl, 14; Na-glutamate, 117; $MgCl_2$, 1; EGTA, 10; MgATP, 3; HEPES-HCl, 5 (pH 7.15); $[Cl^-]_i$ ~20 mM. Single-channel currents were filtered at 0.2 kHz (−3dB) using a 4-pole Bessel filter.

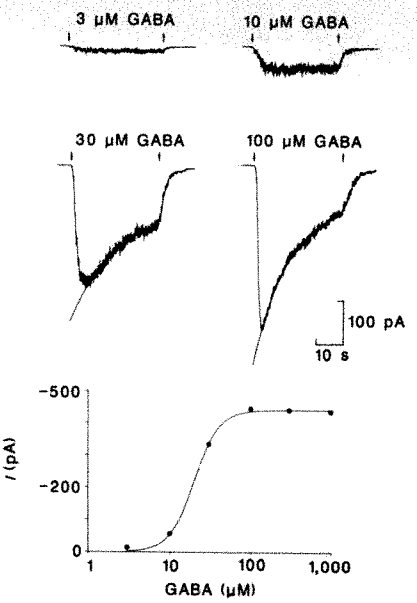

FIG. 3 Dependence on GABA concentration of Cl^- current responses. *a*, 3, 10, 30 and 100 μM GABA was applied to a single α_2 cell at intervals >1 min as indicated by the upward and downward arrows. It was ascertained that the periods between the respective exposures were sufficient to permit recovery from desensitization. Peak amplitudes were obtained by either direct measurement (3 and 10 μM GABA) or extrapolation to zero time by fitting exponential functions (indicated by the superimposed lines) to the decaying part of the currents (30 and 100 μM GABA). Currents were recorded using NMG-filled pipettes (see Fig. 1 legend). Cell was held at −70 mV. *b*, Dose-response curve. The straight line was obtained by fitting the peak currents observed in the presence of 3, 10, 30, 100, 300 and 1,000 μM GABA to equation 1 (see text). The currents have been corrected for desensitization at concentrations ≥30 μM.

secretion of somatostatin. Somatostatin secretion under basal conditions averaged 1.2 ± 0.3 pg per 100 islets min^{-1} ($n = 3$) and increased to 11.8 ± 1.4 pg per 100 islets min^{-1} upon stimulation by 10 mM arginine ($P < 0.001$). The addition of 100 μM GABA did not measurably affect somatostatin secretion, but inclusion of 100 μM bicuculline resulted in an increase to 19.9 ± 2.0 pg per 100 islets min^{-1} ($P < 0.01$). The latter effect suggests that the interstitial concentration of GABA within the arginine-stimulated islet is sufficient to produce a substantial activation of $GABA_A$-receptor Cl^--channels in the α_1 cell. Somatostatin levels were measured using radioimmunoassay[15]. From these observations it seems unlikely that changes in the secretion of somatostatin mediate the influence of GABA on glucagon release. In fact, the stimulation of somatostatin secretion obtained after addition of bicuculline would tend to counteract the stimulatory actions of the latter on glucagon release. This may be the reason why $GABA_A$ receptor antagonists fail to completely reverse the glucose inhibition.

We propose that glucose inhibition of glucagon secretion involves the activation of $GABA_A$-receptor Cl^--channels by GABA co-secreted with insulin from β-cells. This hyperpolarizes the α_2 cell, inhibits spiking, lowers cytoplasmic free Ca^{2+} and reduces glucagon secretion. This model emphasizes the role of paracrine regulatory pathways made possible by the complicated architecture of the endocrine pancreas and provides a flexible system for regulation of glucagon secretion. Any situations associated with the stimulation of insulin secretion will consequently lead to suppression of glucagon release. The model predicts that glucagon secretion will increase under conditions of impaired β-cell function. In fact, non-insulin-dependent diabetes mellitus is often associated with hypersecretion of glucagon, resulting in an aggravation of the diabetogenic action of hypoinsulinaemia[4]. □

TABLE 1 Effects of GABA on glucagon secretion

Line	Incubation medium additive	Glucagon secretion (pg per islet per 30 min)	*n*
1	1.7 mM glucose	11.8 ± 1.6	8
2	1.7 mM glucose + 10 mM L-arginine	19.2 ± 1.8*	8
3	1.7 mM glucose + 10 mM L-arginine + 100 μM GABA	13.9 ± 1.0†	7
4	1.7 mM glucose + 10 mM L-arginine + 100 μM GABA + 100 μM bicuculline	18.2 ± 1.3‡	5
5	16.7 mM glucose	7.5 ± 0.5§	8
6	16.7 mM glucose + 100 μM bicuculline	9.6 ± 0.7‖	5

Pancreatic islets were isolated by collagenase digestion from male guinea-pigs weighing 200–250 g. After tissue culture overnight, batches of 10 islets were incubated in Krebs-Ringer bicarbonate buffer solution (pH 7.4) supplemented with 10 mM HEPES, 2 mg ml^{-1} BSA (fraction V), and additions as in the Table. Incubations were performed for 30 min at 37 °C in a gas phase of 5% CO_2:95% O_2. After incubation, aliquots of the medium were immediately removed for glucagon radioimmunoassay using the 30K antibody[21]. Values are means ± s.e.m. of indicated number of experiments, each experiment consisting of duplicate or triplicate incubations with islets from one animal. Significances of differences were evaluated using Student's *t*-test. * $P < 0.01$ versus line 1; † $P < 0.05$ versus line 2; ‡ $P < 0.05$ versus line 3; § $P < 0.05$ versus line 1; ‖ $P < 0.05$ versus line 5. Difference between lines 1 and 6 not statistically significant ($P > 0.1$).

A neuromodulator of synaptic transmission acts on the secretory apparatus as well as on ion channels

THE mechanisms that underlie synaptic plasticity have been largely inferred from electrophysiological studies performed at sites remote from synaptic terminals. Thus the mechanisms involved in plasticity at the secretory sites have remained ill-defined. We have now used somatic synapses of cultured *Helisoma* neurones[1–3] to directly assess presynaptic ion conductances and study the secretory apparatus. At these synapses we determined the actions of a modulatory neuropeptide, Phe-Met-Arg-Phe-NH_2 (FMRFa), on the release of the neurotransmitter acetylcholine (ACh). Using voltage- and calcium-clamp techniques, we have demonstrated that FMRFa causes a presynaptic inhibition of ACh release by (1) reducing the magnitude of the voltage-dependent calcium current, and (2) regulating the secretory apparatus. The photolabile calcium cage, nitr-5 (refs 3–8), was dialysed into the presynaptic cell. In response to ultraviolet light, calcium was released from nitr-5 and ACh secretion was stimulated. Under conditions of constant internal calcium, FMRFa reduced the rate of ACh release. Thus we conclude that FMRFa reduces the influx of calcium during the action potential and decreases the sensitivity of the secretory apparatus to elevated internal calcium, thereby contributing to a presynaptic inhibition of transmitter release.

† To whom correspondence should be addressed.

Buccal ganglion neuron B5 forms cholinergic chemical connections with buccal neuron B19 in cell culture. Under culture conditions that prevent neurite extension, somata remain spherical, gain the ability to release ACh from the entire soma surface and form chemical synapses with contacting somata[1,2]. We monitored postsynaptic current (p.s.c.) in cholinoceptive neuron B19 using patch pipettes in the whole-cell mode as described previously[3]. To examine the presynaptic actions of FMRFa on ACh release, the presynaptic neuron B5 was depolarized for 4 s from a holding potential of −60 mV to evoke a desynchronized release of neurotransmitter (Fig. 1*a*). This release of neurotransmitter is both calcium-dependent and reversibly reduced by the cholinergic antagonist, tubocurarine[1].

The number of p.s.c.s evoked during 4-s depolarizing steps was counted in control conditions, in the presence of 1 μM FMRFa and after washout. FMRFa reliably reduced the number of depolarization-evoked p.s.c.s ($n = 9$; Fig. 1*a*), but had little effect on the postsynaptic sensitivity to ACh (data not shown). The number of p.s.c.s were normalized to a value of 1.0, which corresponded to the number of p.s.c.s in the control period. FMRFa reduced the depolarization-evoked ACh release to 0.62 ± 0.07 of that of the control (mean ± s.e.m.; Fig. 1*b*). This reduction of ACh release was due to an action of FMRFa and not to synaptic fatigue, because the depolarization-evoked release of ACh was increased, after washout, to 0.85 ± 0.08 of that of the control (Fig. 1*b*; $P < 0.025$, two-tailed Student's *t*-test,

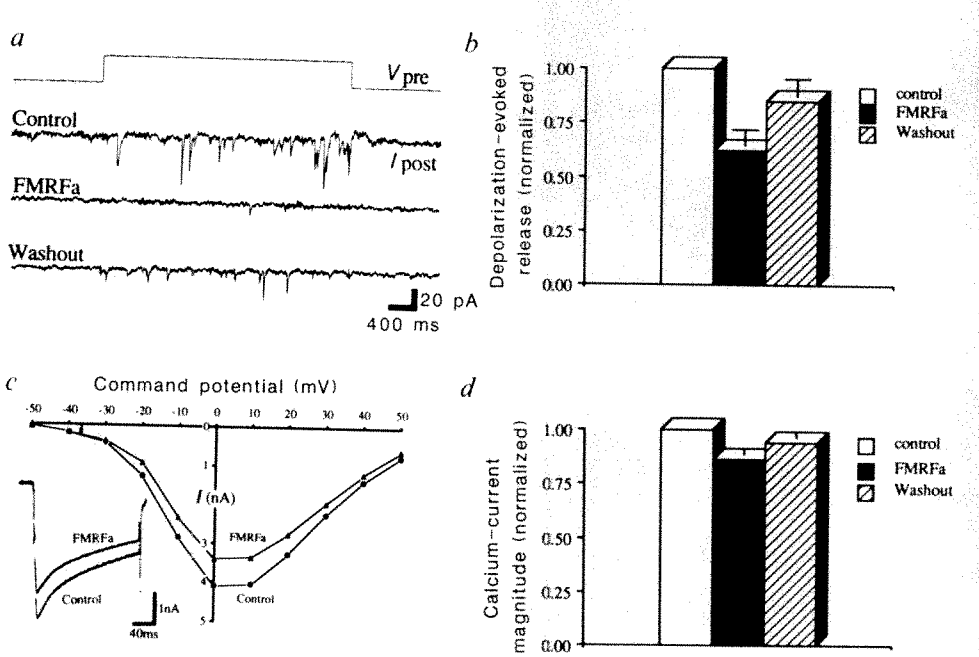

FIG. 1 FMRFa causes a presynaptic inhibition of ACh release and a reduction in the macroscopic calcium current. *a*, Spherical secretory neuronal somata were voltage clamped in the whole-cell configuration. The presynaptic secretory soma was depolarized (V_{pre}) from −60 mV to −15 mV to cause a desynchronized release of ACh, which is seen as a train of inward (downward) p.s.c.s in the current recordings from the postsynaptic cell (I_{post}). Application of FMRFa (1 μM) reversibly reduced the number of desynchronized p.s.c.s (synapse R03). *b*, Histograms demonstrating the reversible reduction in ACh release evoked by FMRFa ($n = 9$). The presynaptic soma was repetitively depolarized for 4 s at 30 s intervals. The average number of p.s.c.s evoked during three trials is represented in each experimental category (mean ± s.e.m.). Values are normalized (see text). *c*, Current–voltage relationship of the HVA calcium current. FMRFa did not change the extrapolated positive reversal potential of the calcium current (neuron C21). The macroscopic calcium current of a secretory soma (inset) is shown in control conditions and after application of 1 μM FMRFa (neuron C36; holding potential −60 mV; command potential 10 mV). *d*, Histograms demonstrating the reversible inhibitory action of FMRFa on the HVA calcium current of secretory somata ($n = 18$). The presynaptic soma was depolarized repetitively for 200 ms at intervals of 30 s. The average peak current during three trials is represented in each experimental category (mean ± s.e.m.). Values are normalized.

METHODS. Neurons B5 and B19 were isolated from buccal ganglia of adult specimens of *Helisoma* and were plated together in freshly-collected snail haemolymph (10%) in 50% salt-free Leibowitz culture medium (GIBCO) plus 40 mM NaCl, 1.7 mM KCl, 4.1 mM $CaCl_2$, 1.5 mM $MgCl_2$, 10 mM K^+-HEPES (Sigma), pH 7.3, and 50 μg ml^{-1} gentamicin sulphate (Sigma)[1,2]. Snail haemolymph plasma prevented cell adhesion to the culture dish and discouraged neurite extension. Culture medium was changed daily. After 2 days, synaptic partners were transferred to poly-l-lysine-coated Petri dishes for immobilization and electrophysiological examination. Neurons were voltage-clamped using Dagan Corporation 8900 patch amplifiers. Postsynaptic pipettes contained 50 mM KCl, 5 mM $MgCl_2$, 5 mM EGTA and 5 mM K^+-HEPES, pH 7.3. Presynaptic neuron B5 was dialysed with a similar internal solution, which contained 35 mM CsCl instead of KCl plus 5 mM ATP and 1 mM GTP. When calcium currents were examined, neurons were bathed in 0 mM NaCl, 4.1 mM $CaCl_2$, 1.5 mM $MgCl_2$, 1.7 mM KCl, 10 mM 4-aminopyridine, 30 mM tetraethylammonium bromide, 30 mM sucrose, 10 mM K^+-HEPES, pH 7.3. Linear leakage and capacity currents were digitally subtracted from depolarizing current traces using pClamp software (Axon Instruments, California).

$t = 2.41$, coefficient of variation (d.f. = 16, $n = 9$). Because FMRFa reduced the number of depolarization-evoked p.s.c.s, this agonist must have been causing a presynaptic inhibition of ACh release from neuron B5.

Neuromodulators can bring about their effects on evoked transmitter release by regulating the activity of voltage-dependent ion channels[9-18]. We voltage-clamped secretory somata of neuron B5 and studied the high-voltage activated (HVA) calcium current, which raises cytoplasmic calcium, which in turn triggers ACh release. In ionic and pharmacological conditions that permitted the selective detection of calcium currents[2], neuron B5 was depolarized from a holding potential of −60 mV to command potentials ranging from −50 to +50 mV. FMRFa (1 μM) reliably reduced the macroscopic current (Fig. 1*c*; $n = 22$). This effect was judged to be a reduction in calcium current, because FMRFa did not affect the extrapolated positive reversal potential of the calcium current (Fig. 1*c*; $n = 4$), and addition of the calcium-channel antagonist Cd^{2+} (5 μM; $n = 12$), which reduced the calcium-current magnitude, reduced the extent of the action of FMRFa.

We determined the magnitude of the HVA calcium current in three control depolarizing steps to constant command potentials spaced at intervals of 30 s. Cells were discarded from further analysis if the current decreased by ≥5% during this period. FMRFa (1 μM) reduced HVA calcium current to 0.86 ± 0.03 (Fig. 1*d*; $n = 18$) of the control calcium current. After washout the current significantly increased to 0.94 ± 0.03 of the control current ($P < 0.025$, $t = 2.08$, d.f. = 34, $n = 18$ cells).

In non-neuronal cells, the sensitivity of the secretory apparatus to internal calcium is regulated by multiple intracellular signals[19-22]. Thus, we determined whether FMRFa additionally regulates the Ca^{2+}-dependent secretory apparatus. Because FMRFa affects the calcium current and thus calcium influx, it was necessary to control the internal free-calcium so that it was independent of transmembrane ion fluxes. We used the photolabile calcium cage, nitr-5 (Calbiochem)[3-8], to elevate the internal level of free calcium and evoke transmitter release, thereby dissociating voltage-dependent calcium current from the calcium-dependent secretory event. Nitr-5 (20 mM) loaded to 90% of its full capacity with 18 mM Ca^{2+}, was included in the internal patch-pipette solution in place of EGTA. Characteristically, after 1-5 min of presynaptic recording, the background rate of p.s.c.s increased, indicating successful dialysis (estimated pre-photolysis calcium level ~400 nM). Exposure to ultraviolet light (340 nm) photolytically released calcium from the cage and caused a sustained increase in the rate of p.s.c.s (Fig. 2*a*; $n = 11$). These p.s.c.s were judged to be due to ACh because 10 μM tubocurarine reversibly reduced their magnitude. Ultraviolet light did not increase the background rate of p.s.c.s when cells were dialysed with nitr-5 that had not been loaded with calcium (0 mM Ca^{2+}, 20 mM nitr-5; $n = 4$).

We tested the effect of FMRFa on the secretory apparatus. Neurons were voltage clamped at −80 mV and the rate of calcium-dependent ACh release was increased by the photolytic release of calcium from nitr-5 (Fig. 2*a*). A puff of FMRFa (5-10 s) was applied to cell pairs. In all of nine applications (eight synapses), FMRFa (1-10 μM) reversibly reduced the rate of p.s.c.s (Fig. 2). In an additional two preparations bathed in 0 mM Ca^{2+}/10 mM Mg^{2+} saline, FMRFa had the same effect. The rate of transmitter release was quantified by calculating the reciprocal of the interval between successive p.s.c.s. Because transmitter release has a statistical nature, the measured rate of transmitter release was smoothed using the moving bin method[3,23] over three events. Figure 2*c* shows that FMRFa reversibly reduced the rate of transmitter release. In Fig. 2*d*, normalized data from all cell pairs examined are shown. FMRFa reduced the average rate of p.s.c.s to 0.35 ± 0.11 of the control rate, and after washout the rate significantly increased to 0.66 ± 0.1 of the control value ($P < 0.025$, $t = 2.15$, d.f. = 16, $n = 9$).

Because nitr-5 is probably the dominant calcium buffer in the dialysed cell we expected free calcium to be unaffected by FMRFa. In four control experiments this was confirmed using fura-2 (refs 7, 24). Calcium was photolytically released from nitr-5 to yield an estimated free-calcium level of ~1 μM. Appli-

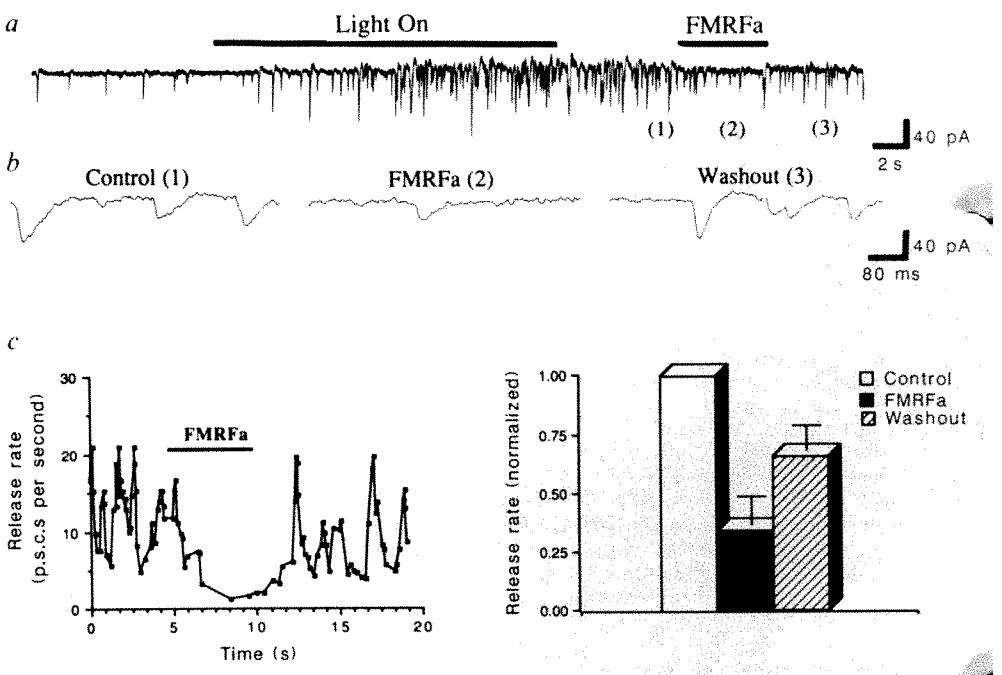

FIG. 2 FMRFa reduces the rate of p.s.c.s under conditions of constant internal calcium. Whole-cell recordings were made from presynaptic neuron B5 using patch pipettes that contained 20 mM nitr-5, 18 mM $CaCl_2$, 35 mM KCl, 5 mM $MgCl_2$, 5 mM ATP, 1 mM GTP, 400 μM fura-2, 5 mM K^+-HEPES, pH 7.3. The release of neurotransmitter was detected as inward current transients (p.s.c.s). *a*, Epi-illumination with ultraviolet light, supplied by a xenon-arc lamp through the ×40 oil-immersion objective of a Nikon Diaphot inverted microscope, photolytically released calcium and triggered an increase in p.s.c. frequency. After ceasing illumination, ACh release was sustained. Subsequent application of 1 μM FMRFa in 0.1% fast green in culture medium from a puffer pipette decreased the rate of p.s.c.s. *b*, Expanded records of the p.s.c.s in control conditions (1), during the 5-s FMRFa puff (2) and after washout (3). P.s.c.s were readily detected above the noise levels of the recordings (synapse N13 in *a* and *b*). *c*, Rate of p.s.c.s (see text for method of calculation) in response to elevated internal calcium. Puffer application of FMRFa (10 μM) rapidly reduced the rate of ACh release. At the end of FMRFa application, an initial return towards the control rates of p.s.c.s was detected within seconds of washout (synapse N17). *d*, Collective data showing the normalized rate of p.s.c.s. The average rate of release was calculated for each synapse over 3-s periods immediately before FMRFa application (control), during the last 3 s of FMRFa application and during 2-5 s of washout. FMRFa reliably reduced the rate of ACh release. Partial recovery during the washout period may be due to incomplete washout of the agonist. The larger inhibitory effect of FMRFa on transmitter release evoked by caged calcium as compared with transmitter release evoked by depolarization (Fig. 1*b*) was probably due to different doses of FMRFa.

cation of FMRFa (10 μM) did not change this level of free calcium in nitr-5-loaded presynaptic cells ($n = 4$). Thus, FMRFa reversibly decreased the rate of calcium-dependent ACh release under conditions of constant and elevated calcium.

There are numerous potential mechanisms that could bring about FMRFa's action on the secretory apparatus. In squid, Ca^{2+}/calmodulin-dependent protein kinase II, which phosphorylates the vesicle-associated protein synapsin I (ref. 25), increases the release of transmitter without affecting the initial macroscopic calcium-current[26]. It is postulated that phosphorylation increases the number of vesicles available for transmitter release thereby causing synaptic facilitation. In *Helisoma*, FMRFa might have an opposing action, promoting a dephosphorylation of vesicle proteins to reduce the number of vesicles available for transmitter release, thereby contributing to presynaptic inhibition.

The neuropeptide FMRFa, therefore, acts through multiple routes to bring about a presynaptic inhibition of transmitter release. First, FMRFa reduces the HVA calcium current of the secretory membrane. Second, FMRFa decreases the rate of ACh release in response to a constant level of presynaptic internal free-calcium. This is a unique observation in neuronal tissue. Because intracellular signals commonly regulate the sensitivity of the secretory apparatus to free calcium in non-nervous secretory tissue[19–22], it will be intriguing to determine whether this is a widespread regulatory mechanism used throughout synaptic terminals. □

ACKNOWLEDGEMENTS. We thank Drs C. Drewes, J. Johansen, B. MacVicar and R. S. Zucker for their comments on the manuscript and to R. Doyle for his technical assistance. This work was supported by the NIH and the Iowa State University Biotechnology Council (P.G.H.) and the MRC of Canada and a NATO International Collaboration Fellowship (K.L.). P.G.H. is an Alfred P. Sloan Fellow.

Caenorhabditis elegans has scores of homoeobox-containing genes

Thomas R. Bürglin, Michael Finney, Alan Coulson* & Gary Ruvkun

HOMOEOBOX-containing genes control cell identities in particular spatial domains, cell lineages, or cell types during the development of *Drosophila*[1,2] and *Caenorhabditis elegans*[3–5], and they probably control similar processes in vertebrates[6–9]. More than 80 genes with homoeoboxes that have sequence similarities ranging from 25 to 100% have been isolated by genetic means or by DNA hybridization to previously isolated genes[10]. We synthesized 500–2,000-fold degenerate oligonucleotides corresponding to a set of well-conserved eight amino acid sequences from the helix-3 region of the homoeodomain[11]. We screened *C. elegans* genomic libraries with these probes and identified 49 putative homoeobox-containing loci. DNA sequencing confirmed that eight out of ten selected loci had sequences corresponding to the conserved helix-3 region[11] plus additional flanking sequence similarity. One of these genes contained a sequence corresponding to a complete *pou*-domain[12] and another was closely related to the homoeobox-containing genes *caudal/cdx-1*[13,14]. The putative homoeobox loci were mapped to the physical contig map of *C. elegans*[15,16], allowing the identification of potentially corresponding genes from the correlated genetic map. We estimate that the number of homoeobox-containing genes in *C. elegans* is at least 60, constituting ~1% of the estimated total number of genes[17].

An eight amino-acid degenerate motif from the helix-3 region of the homoeodomain is only found in homoeodomain proteins when the EMBL database is searched[11]. To screen the *C. elegans* genome for sequences corresponding to this conserved set of amino-acid sequences, we designed five 512-fold to 2,048-fold degenerate oligonucleotide probes (23 bases) corresponding to these amino-acid sequences (Fig. 1*a*). The HB-1 probe was designed to detect a large set of homoeobox-containing gene classes (for example, *Antp, Abd B, caudal, Dfd, lab, mab-5, ro, Ubx, zen-1*; see ref. 10) with no mismatches, and the *eve, en* and *bcd* classes[10] with one mismatch. The PRD-1/PRD-2 set of oligonucleotides detects homoeoboxes of the *paired* class[10] with no mismatches, whereas the POU-1/POU-2 set was designed to detect members of the *pou*-domain class with one or no mismatch[12]. Statistical analysis indicates that with two or fewer mismatches, few spurious random hybridizations to these probes would be expected in the small *C. elegans* genome (100 million base pairs; J. Sulston and A.C., unpublished observation).

To establish the specificity of the degenerate oligonucleotides and the hybridization conditions we probed a panel of sequenced homoeobox-containing genes that had zero to seven mismatches with HB-1, PRD-1, and PRD-2 probes (Fig. 1*b*). We determined conditions that yielded strong hybridization to fragments with two or fewer mismatches. Using these conditions and probes, ~35 bands of varying intensities could be distinguished on a genomic Southern blot of *C. elegans* DNA (Fig. 1*c*).

We screened genomic cosmid libraries[15] containing two to four genome equivalents with these probes and selected 136 cosmids. These cosmid DNAs were digested with *Eco*RI, transferred to Southern blots and hybridized separately with HB-1, PRD-1/PRD-2, and POU-1/POU-2. The cosmids were also fingerprinted and their positions in the 90–95%-complete physical map of the *C. elegans* genome[15,16] were determined. Many of the isolated cosmids overlapped, so that finally 50 independent hybridizing loci were isolated (Table 1) and assigned to contigs as large as 8 megabases.

The contig map indicated that four loci that we had isolated mapped to the same cosmids as known homoeobox-containing genes. One locus (no. 47) was the known homoeobox-containing gene *unc-86* (ref. 5). Three loci (nos. 7, 20 and 31) coincided with homoeobox-containing genes isolated and sequenced by other groups: *ceh-1* and *ceh-11* (N. Hawkins and J. McGhee, personal communication) and *ceh-11* and *ceh-12* (D. Schaller,

C. Wittmann, A. Spicher, F. Müller and H. Tobler, personal communication).

To verify further homoeobox-hybridizing loci, we sequenced the region flanking the probe-hybridizing region from ten independent cosmids. For three of the loci we obtained sequences corresponding to complete homoeodomains, as shown by the presence of conserved residues throughout the 60 residues (Fig. 2*a*). For five loci, introns in the genomic subclones only allowed partial determination of the protein sequences; nevertheless, these sequences matched conserved residues throughout the sequenced region. Because these conserved residues have only been found in proteins containing complete homoeodomains, and because the probability of a match to the spectrum of homeodomain amino acids in that region is 4×10^{-11} or less, these loci almost certainly correspond to homoeobox-containing genes. These genes were designated *ceh-2* to *ceh-8* and *ceh-14* (for *C. elegans* homoeobox in accordance with the *Caenorhabditis* Genetics Center). Two loci (nos. 17 and 27) did not encode a homoeodomain; extra nucleotides disrupted the reading frame in the oligonucleotide-hybridizing region, and no flanking homology was observed.

The *ceh-6* homoeodomain is similar to homoeodomains of the products of the *pou*-domain class of genes[12]. All products of the *pou* class contain a conserved *pou*-specific domain upstream of the homoeodomain. Using a degenerate oligonucleotide probe (26 bases) corresponding to this *pou* domain (POUSP-A; Fig. 1*a*), we probed cosmids from all the putative homoeobox-containing loci, and found that only *ceh-6* and *unc-86* hybridized. Further sequencing showed that *ceh-6* contained a sequence corresponding to a *pou*-domain of the *pou*-III subclass[18]. The deduced amino-acid sequence has 92% identity to the *pou*-specific domain of the human *Brn-1* gene (Fig. 2*b*). None of the six other loci isolated with the POU-1/POU-2 homoeobox probes hybridized to the POUSP-A probe (Table 1). Sequence verification is necessary to establish whether these loci contain amino-acid sequences corresponding to *pou*-class homoeodomains or other closely related homoeodomains.

The deduced amino-acid sequence encoded by the gene *ceh-3* is most similar to that of the *Drosophila* gene *caudal*[13] and the mouse gene *cdx-1*[14] (67–69% identity). Additional amino acids upstream of the homoeodomain are conserved in all three (Fig. 2*c*). The deduced amino-acid sequence of the homoeodomain of *ceh-14* is significantly more similar to that of *mec-3* (62% identity) than to other homoeodomains. The genes *ceh-5* and *ceh-7* encode homoeodomains so divergent from other homoeodomains (between 25–45% identity) that they define new classes.

The presence in *C. elegans* of the homoeodomain classes *caudal* (*ceh-3*), *Antp*[4,19] (*mab-5*), *engrailed*[19], *paired*[19] (putative loci nos. 2, 11, 12, 33 and 40), and of the *pou*-III and

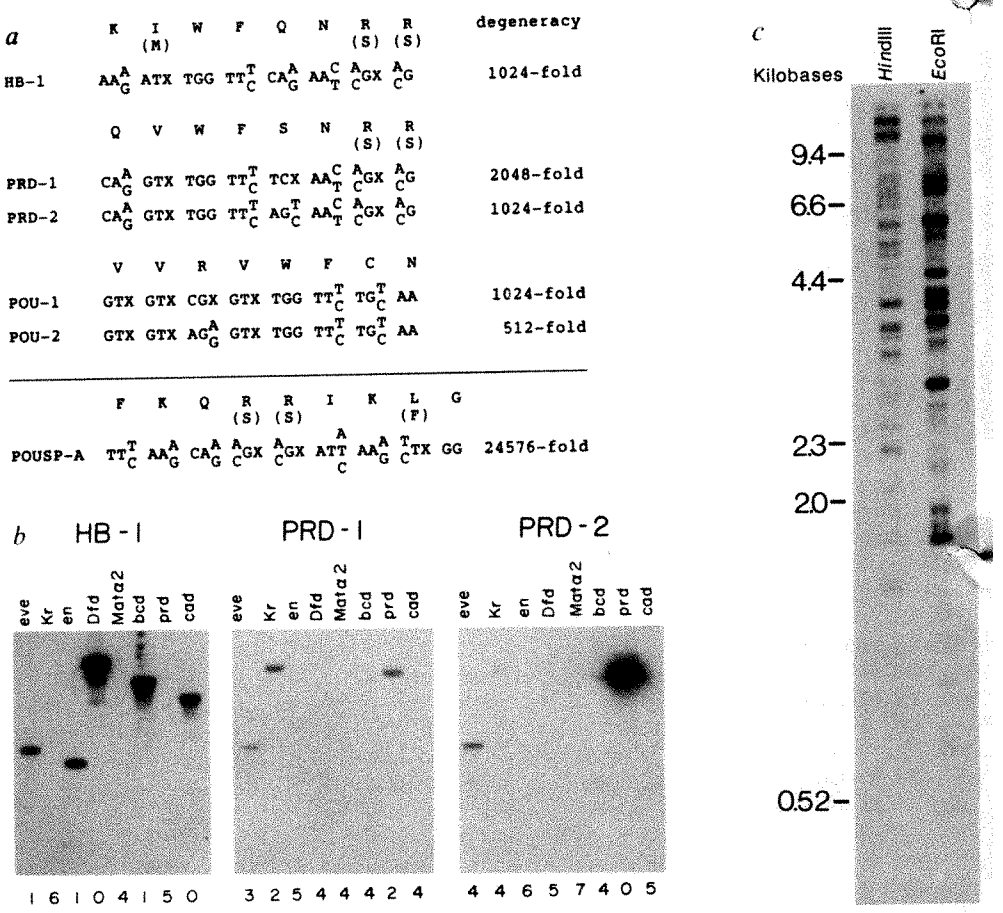

FIG. 1 *a*, Sequences of the degenerate oligonucleotides HB-1, PRD-1, PRD-2, POU-1, POU-2 and POUSP-A and their conceptual translation. The single-letter code is used to designate amino-acid residues. Amino acids in brackets have not been found at that position in the homoeodomain, but were included as a by-product of the degenerate codons. The reverse complements of HB-1, PRD-1 and PRD-2 were used in the experiments. *b*, Triplicate Southern blots of equal amounts of restriction digested complementary DNA or genomic clones of the *Drosophila* genes *eve, en, Dfd, bcd, prd, caudal* and *Kr*, and yeast *MATα*2 (refs. 10 and 24) were probed with HB-1, PRD-1 and PRD-2, respectively. The numbers beneath each panel indicate the minimal number of mismatches for each oligonucleotide with the test sequence. Whereas fragments with no or one mismatch hybridized strongly, some weaker hybridization was observed with two to four mismatches. The gene *Kr* does not have a homoeobox, but fortuitously has only two mismatches with PRD-1. Vector sequences and other non-homoeobox-containing restriction fragments did not hybridize. The variability of signal intensity in sequences with the same number of mismatches was probably due to non-equal representation of each sequence in the degenerate oligonucleotide mixture and the position at which the mismatch(es) occurred in the duplex. *c*, Southern blot of *C. elegans* genomic DNA (10 μg per lane) digested with either *Eco*RI or *Hin*dIII and probed with a mixture of HB-1, PRD-1 and PRD-2. About 35 bands can be discerned above the background.

METHODS. Oligonucleotides were synthesized on a Biosearch Inc. synthesizer and precipitated at 1 mg ml^{-1} in 10 mM $MgSO_4$ with five volumes of ethanol. The oligonucleotides were 5′-end-labelled with T4 kinase according to Maniatis *et al.*[25] using crude 7,000 μCi mmol^{-1} [γ-^{32}P]ATP (ICN). Restriction digests, gel electrophoresis, and Southern transfers onto Genescreen were done as described[25]. Hybridization was carried out as modified from Wood *et al.*[26]: filters were prehybridized in 6 × SSC, 5 × Denhardt's solution, 0.05% Na-pyrophosphate, 1% SDS and 100 μg ml^{-1} transfer RNA for 1 h to overnight at 37 °C. Approximately 2–5 μCi of labelled oligonucleotides per ml of hybridization solution (composition as before) were hybridized for 14–48 h at 42 °C. Filters were washed three times in 6 × SCC and 0.05% sodium pyrophosphate, at room temperature for 30 min total time, and rinsed in 3.0 M tetramethyl ammonium chloride (Me_4NCl) 50 mM Tris buffer, pH 8.0, and 0.2 mM EDTA. Filters were washed twice in 3.0 M Me_4NCl, 50 mM Tris buffer, pH 8.0, and 0.2 mM EDTA at 53 °C for 15 min each time.

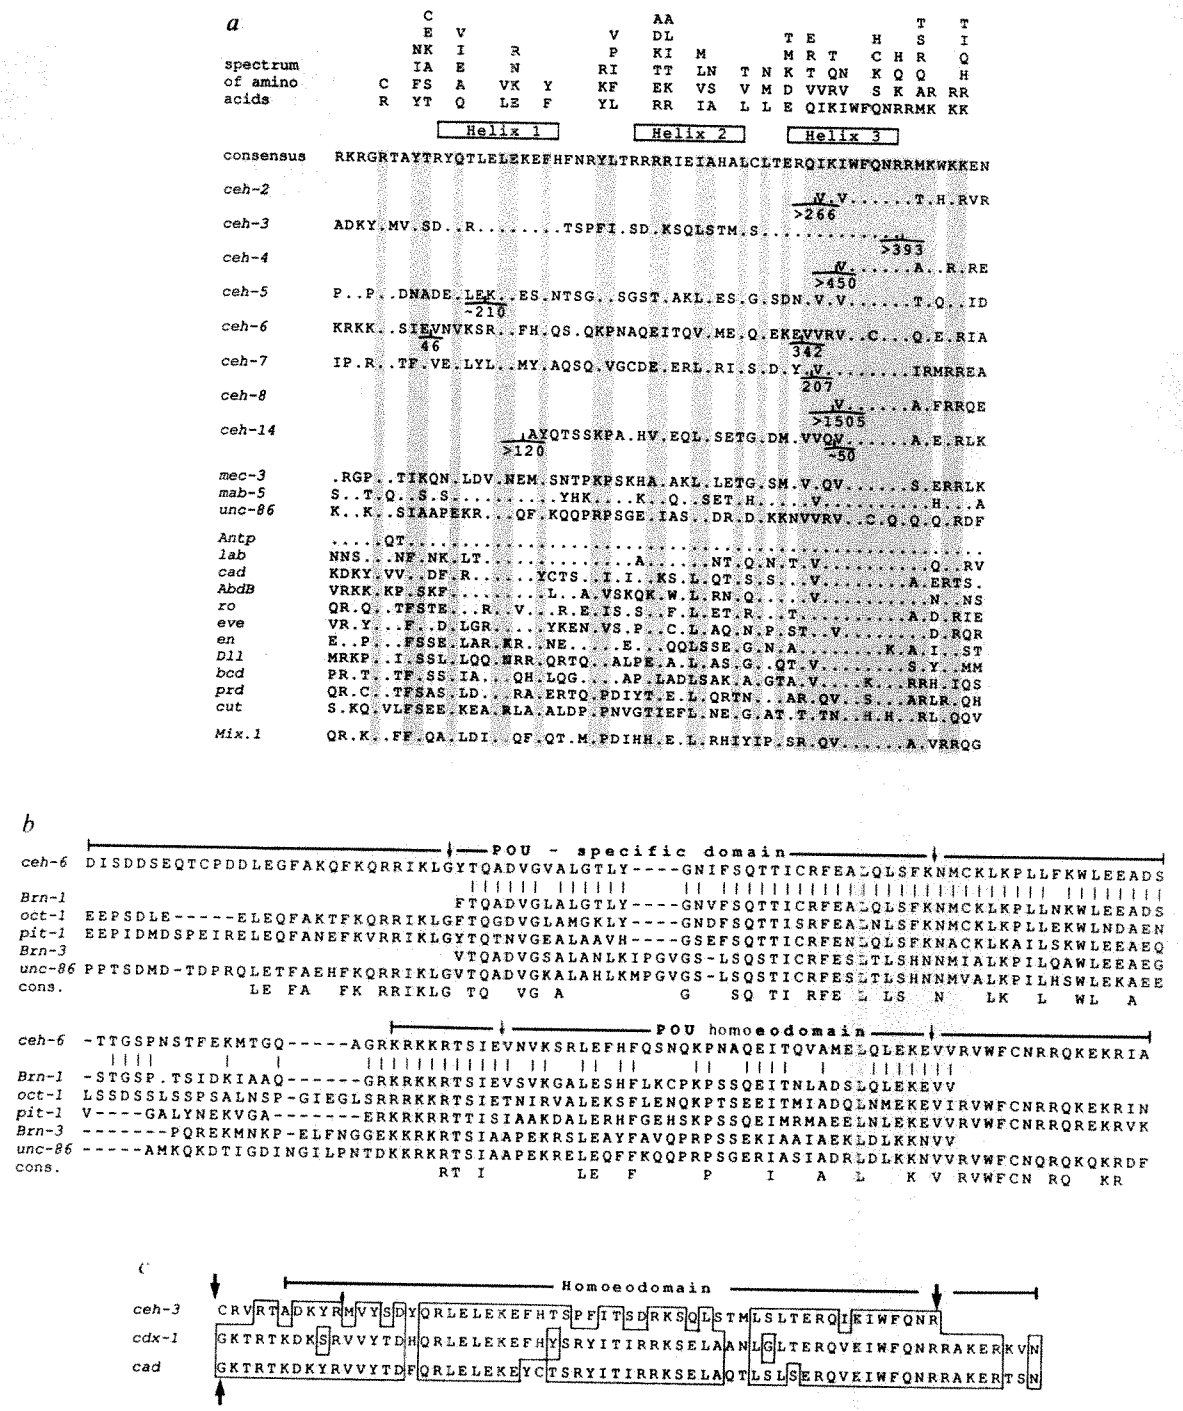

FIG. 2 *a*, Comparison of the deduced sequences of the homoedomains of the *ceh-2* to *ceh-8* and *ceh-14* gene products and selected *C. elegans*, *Drosophila* and frog homoeodomains[3,4,5,10,27,28]. Single-letter code designates amino-acid residues. Dots indicate identity to an arbitrary consensus[11]. Amino acids listed above the consensus are the spectrum of residues observed at the least variable 30 positions of the homoeodomain[10] (yeast homoeodomains not included). Note that for the *ceh* genes there are matches to these positions outside the eight matches corresponding to the oligonucleotide probes. Only one residue of the *ceh-3* sequence and one in *ceh-14* violate this rule. Helices are denoted according to Otting *et al.*[29]. The ceh genes detected here hybridized with 0 to 3 mismatches to HB-1 or PRD-1/PRD-2. The spurious hybridizing clones nos. 7, 27 hybridized with an additional loopout. The genes *ceh-2* to *ceh-8* and *ceh-14* all have introns (positions indicated by arrows) in the homoeobox (sizes indicated underneath each line) based on genomic DNA sequences. The donor and acceptor sequences of these introns conform to the well-conserved *C. elegans* splice sites[17]. The position of the intron in *ceh-2* and *ceh-7* is the same as the position of the intron in the *Drosophila* genes *labial*[10] and *Distal-less*[27], whereas that in *ceh-4*, *ceh-8* and *ceh-14* is the same as in the frog gene *Xhox3* (ref. 30). *b*, Alignment of the deduced amino acid sequences of the *ceh-6*, *Brn-1*, *oct-1*, *pit-1*, *Brn-3* and *unc-86* gene products[12,20]. That of *ceh-6* is 92% identical to that of *Brn-1* in the POU-specific domain, and 69% in the POU homoeodomain (vertical-dashes indicate identities). Arrows indicate introns in *ceh-6*. *c*, Alignment of the deduced homoeodomain sequences of the *ceh-3*, *caudal*[12] (cad) and *cdx-1* gene products[13]. The *ceh-3* partial homoeodomain is 67–69% identical to that of *cdx-1* and *cad*. Note the conservation of amino acids just upstream of the homoeodomain, and the similar location of the intron for *caudal* and *ceh-3* (indicated by arrows).

METHODS. Homoeobox-hybridizing *Eco*RI fragments were subcloned into Bluescribe$^-$ (Stratagene) or M13mp18 using standard techniques[25] and sequencing was carried out using Sequenase (USB) according to manufacturer's instructions. In most cases some initial sequence was obtained using the degenerate oligonucleotides as primers. Sequences were extended by synthesizing specific primers.

TABLE 1 Hybridizing loci

Loci no.	Cosmid name	No. of ind. clones	Probe	Chromosome	Gene
1	AC5	2	HB-1	I	*ceh-5*

The MIT and the MRC cosmid libraries[15] (6,800 or 6,000, respectively, individual clones stored in microtitre wells) were plated on Biodyne filters (ICN) on LB plates containing 50 μg ml^{-1} ampicillin, 5 μg ml^{-1} sulbactam (Pfizer). Filters were processed by autoclaving[23]. Hybridization with a mixture of HB-1/PRD-1/PRD-2 or POU-1/POU-2 was as described (Fig. 1, legend). DNA was prepared from 136 cosmids, digested with *Eco*RI, transferred to Genescreen (NEN) and hybridized with HB-1 or PRD-1/PRD-2 (nos. 1–43), or with POU-1/POU-2 or POUSP-A (nos. 44–50). For each locus, a representative cosmid name is shown as well as the number of independent clones corresponding to each locus that were identified. The probe that hybridized and a crude estimate of the hybridization signal strength is also listed. The new homoeobox-containing genes identified in this study are *ceh-2* to *ceh-8* and *ceh-14*. The genes *ceh-1*, *ceh-11* and *ceh-12* were independently isolated and sequenced by others (see text). The number of loci is a minimum estimate: the probes would not detect the highly divergent homoeobox gene *cut*[10] because of too many mismatches (4), nor would they detect homoeobox-containing genes that had an intron within the 23-base probe region, nor those genes that are 'hybrids' between the probe classes used. Genes that were not represented in the cosmid libraries would have also been missed. Because we allowed for probe mismatches, however, highly divergent homoeodomains could be identified; indeed *ceh-6* was detected using the PRD-1/PRD-2 probes.

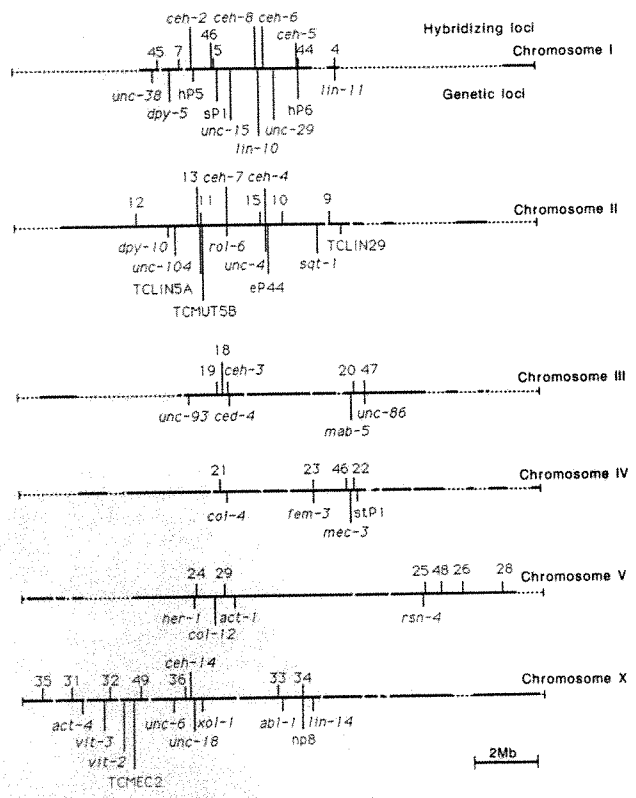

FIG. 3 Location of confirmed and putative homoeobox-containing loci on the genetically correlated physical contig map[15,16]. Each cosmid clone was fingerprinted as described[15] and assigned to contigs based on that fingerprint. Genetic markers were similarly assigned to contigs. Solid bars on each chromosome indicate genetically mapped contigs. Selected genetic markers are indicated below each chromosome (genes are italicized, restriction fragment length polymorphisms are not). Homoeobox-containing genes that have been sequenced in this study are shown above each chromosome (*ceh-2* to *ceh-8*, *ceh-14*). Homoeobox-hybridizing loci that have not been verified in this study are numbered according to Table 1. Some of the cosmids identified contained several hybridizing bands and thus could contain closely linked homoeobox genes. The map is scaled according to physical distance in megabases (Mb). Genetic distance varies according to location. Four homoeobox loci mapped to the same cosmids as previously mapped genetic loci (no. 4, *ceh-4*, *ceh-7* and no. 23). Precise mapping, however, of the hybridizing region to the same transcription unit that is affected by mutations in these genes is necessary before congruity between the two can be established. In fact, two loci (*ceh-7* and no. 23) are distinct from the physically very close and sequenced genes *rol-6*[31] and *fem-3* (T. Rosenquist and J. Kimble, personal communication). For those regions where the physically mapped genetic markers are separated from the homoeobox genes by hundreds of kilobases, candidate genetic loci can be inferred from the correlated genetic and physical distance.

pou-IV subclasses[18] (*ceh-6*, *unc-86*), suggests that these, and probably many of the other classes, were already present in the common ancestor of *C. elegans*, *Drosophila* and vertebrates. The new classes of homoeobox-containing genes so far found only in *C. elegans* (*mec-3* and *ceh-14*, *ceh-5*, *ceh-7*) may also be present but as yet undetected in vertebrates and other invertebrates.

Many of the homoeobox loci were mapped with a resolution of 30–50 kilobases to large contigs allowing their location relative to each other to be determined (Fig. 3). These genes seemed to be randomly distributed along the contigs; no clusters of homoeobox-containing genes like those in *Drosophila* and vertebrates[2,20,21] were detected. Some cosmids (nos. 3, 9, 18, 41 and 49; Table 1) contained several hybridizing bands and thus possibly more than one homoeobox gene.

About 125 genetic markers have similarly been mapped to the *C. elegans* contig map, thus aligning large stretches of the genetic and physical maps. The mapping of homoeobox-containing genes within these contigs immediately suggested potential genes to which they may correspond (Fig. 3). One of the loci mapped to a cosmid that contained the *lin-11* gene, which controls cell identities in some vulval precursor cells[22] (G. Freyd, S. Kim and H. R. Horvitz, personal communication). Likewise, *ceh-4* mapped to the same cosmid that contained allele-specific polymorphisms in the neural identity gene *unc-4* (D. Miller, personal communication). Many of the other loci identified here may not have been identified by mutation. Their location on the genetic map can be used to obtain mutations in these genes in a directed fashion.

Because eight of the ten putative homoeobox loci that we sequenced, including a weakly hybridizing locus, actually contained a homoeobox, and because four of the loci we detected were confirmed by others, we expect that most (~85%) of the 36 other loci isolated are homoeobox-containing genes. Poisson analysis of the number of times each locus was isolated predicts that for statistical reasons we should have missed ~20 loci that could be represented in cosmid libraries. Indeed, we failed to detect cosmids containing *mab-5*[4] and *mec-3*[3], both of which should have been detected by our probes. A conservative estimate for the number of homoeobox-containing genes in *C. elegans* that our probes would detect (see Table 1) is thus 60, or ~1% of the estimated total number of genes[17].

Clone arrays similar to that for *C. elegans* are being constructed for many organisms as chromosomal walks towards genetic loci or as a prelude to genome sequencing. Whereas the complete DNA sequence of such arrays may be years away, the identification and mapping of particular sequence motifs (such as zinc-fingers, kinases), as we have shown here with the homoeodomain, can highlight specific genetic regions for further study. □

ACKNOWLEDGEMENTS. We thank Joe Gatto for technical assistance, Mike Cherry for synthesizing oligonucleotides, and Rich Cate for discussions. We thank our colleagues for critical reading of the manuscript and G. Freyd, N. Hawkins, D. Miller and D. Schaller for exchange of data before publication. DNAs were gifts from Drs W. Gehring, M. Noll, C. Nüsslein-Volhard and G. Struhl. This work was supported by a Hoechst grant to the Massachusetts General Hospital, Department of Molecular Biology. T.B. is a recipient of an EMBO fellowship.

A Fos protein containing the Jun leucine zipper forms a homodimer which binds to the AP1 binding site

Manfred Neuberg, Jürgen Adamkiewicz, John B. Hunter & Rolf Müller

Institut für Molekularbiologie und Tumorforschung (IMT), Philipps-Universität Marburg, Emil-Mannkopff-Strasse 2, D-3550 Marburg, FRG

THE TPA (12-*O*-tetradecanoyl-phorbol-13-acetate) responsive element (TRE) is recognized by the inducible transcription factor AP1, a heterodimeric complex of Fos- and Jun-protein subunits, which each contain a specific structure known as the leucine zipper through which they interact[1–7]. Studies using site-directed mutagenesis have shown that a basic region adjacent to the leucine zipper in Fos is crucial for the interaction of the Fos–Jun complex with the TRE, and probably represents a site of interaction with DNA. The functionally crucial amino acids in this region are almost completely conserved between Fos and Jun (refs 6, 7 and 11; M.N. and R.M., unpublished results), indicating the formation of a nearly symmetrical DNA-binding site in the Fos–Jun complex. Whereas Jun can form a homodimeric protein complex which binds to the TRE, Fos is unable to do so. The Fos–Jun heterodimer, however, possesses at least a 30-fold-higher affinity for the TRE than does the Jun–Jun homodimer, indicating cooperative binding[6–11]. Because Fos cannot form a homodimer it is not known whether Fos specifically recognizes part of the TRE or has a different role in the binding of the Fos–Jun complex to DNA. Here we report that exchanging the leucine zipper in Fos with that of Jun generates a protein (termed Ψ-Fos) that can form a complex with Fos. This Fos–Ψ-Fos complex, and to a lesser extent a homodimeric Ψ-Fos complex, exhibits specific binding to the TRE. This finding strongly supports the hypothesis that Fos and Jun form a nearly symmetrical DNA-binding site that interacts with the palindromic TRE.

To engineer a recombinant Fos protein that was able to form a homodimeric DNA-binding site we first introduced two new restriction sites into the *fos* gene by site-directed mutagenesis (without altering the coding capacity) at the 5′- and 3′ ends of the leucine-zipper-encoding DNA sequences. The entire Fos zipper could then be exchanged with a double-stranded synthetic oligonucleotide representing the leucine repeat of Jun (see Fig. 1). The Ψ-Fos protein encoded by this gene differs from Fos only in the 24 amino acids that space the leucine residues. The Ψ-Fos protein was tested for its ability to form a pseudo-homodimer with Fos in an *in vitro* complex-reconstitution assay[5]. The formation of such a complex was analysed by using a Fos protein truncated at its C-terminal end, which enabled the two constituents to be distinguished by their differential

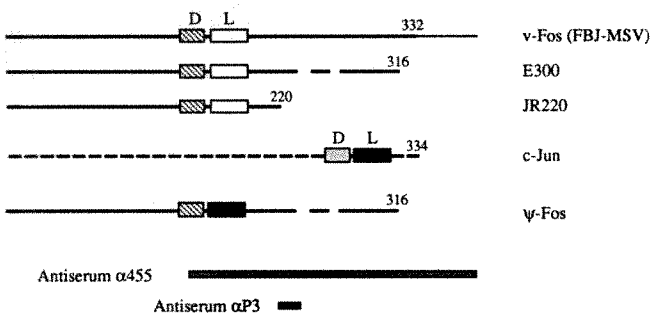

FIG. 1 Structure of Fos and Jun proteins encoded by the constructs used in this study. Numbers indicate amino acids; D, DNA-binding sites in Fos and Jun; L, leucine zippers in Fos and Jun; bold lines, Fos sequences; thin lines, v-Fos (FBJ-MSV)-specific sequences (that is, different from c-Fos sequences because of a frame-shift deletion[16]); dashed bold lines, Jun sequences. The stippled boxes at the bottom show those regions in Fos representing the antigens used to produce the antibodies α455 and αP3. METHODS. Two restriction sites (*Sac*I and *Sph*I) were introduced by site-directed mutagenesis[5,11] at nucleotide positions 2,418 and 2,457 (ref. 13) of E300. The leucine-zipper regions could thus be excised with *Sac*I and *Sph*I and be replaced with a synthetic double-stranded oligonucleotide encoding the Jun leucine zipper. Details of the other constructs have previously been published[5,11,15]. Antiserum αP3 was raised in a rabbit against a conjugate of thyreoglobulin and a synthetic oligopeptide representing Fos amino acids 214 to 226 by using a water-soluble carbodiimide as the coupling agent[17]. Antiserum α455 has previously been described[12].

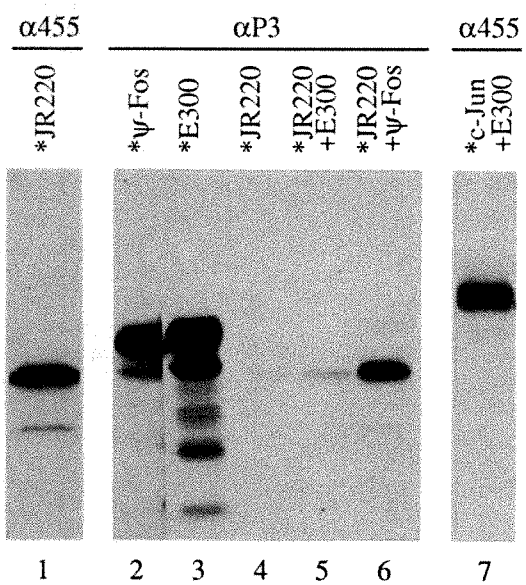

FIG. 2 *In vitro* protein-complex formation. The indicated *in vitro* translated proteins (asterisk denotes ^{35}S-methionine labelled proteins) were incubated either individually or together with another protein to allow complex formation as described [5]. The proteins were then immunoprecipitated by using the indicated antibodies and analysed by SDS-PAGE followed by fluorography. The weak bands in lanes 4 and 5 are due to a small degree of unspecific binding to the protein A used in the immunoprecipitation (data not shown).

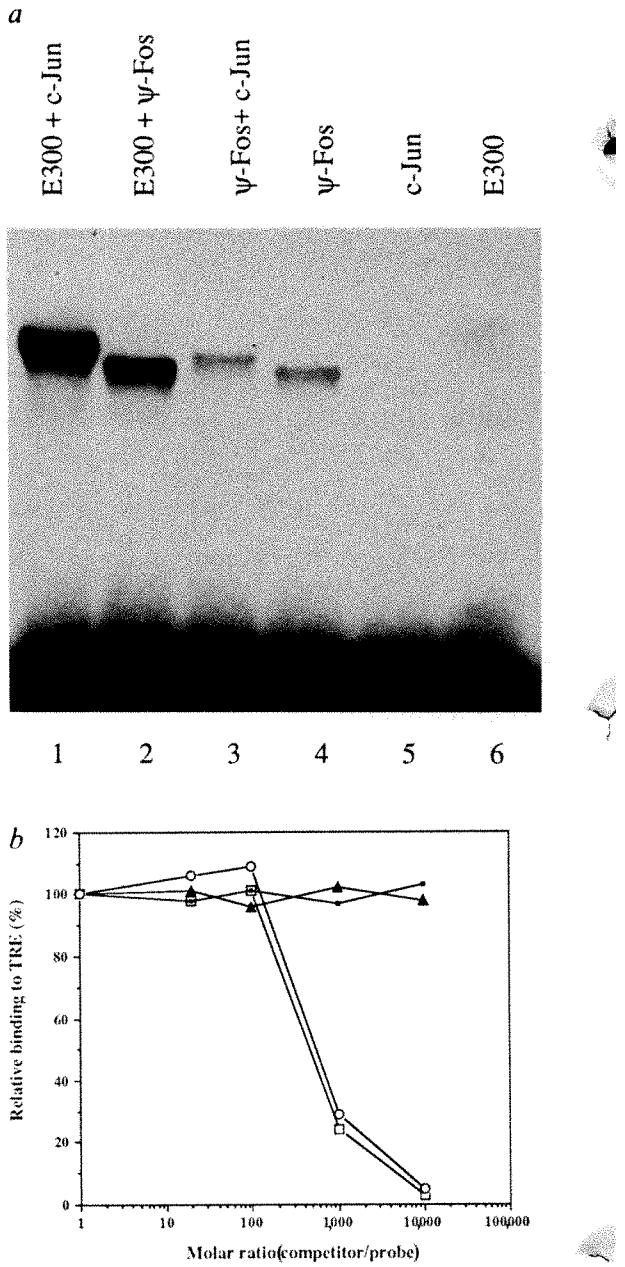

FIG. 3 *a*, TRE-binding properties of Fos, Ψ-Fos and Jun protein complexes. The indicated proteins were allowed to form complexes as in Fig. 2, incubated with a ^{32}P-labelled double-stranded oligonucleotide representing the collagenase TRE[11,16] and analysed in a band shift assay[18,19]. The free oligonucleotide is at the bottom of the gel. The weak bands in the Fos lane represent unspecific binding as shown by competition experiments (data not shown). *b*, Specificity of the Fos–Jun and Fos–Ψ-Fos complexes to the TRE. Binding of protein complexes to the TRE was determined after pre-incubation with different concentrations of either specific or non-specific oligonucleotides (for example, a TRE-containing oligonucleotide identical to the probe or an oligonucleotide of random sequence but the same size as the specific competitor). Complexes were analysed as in *a* and the relative percentage of binding was estimated by densitometric scanning of the autoradiogram (no competitor was taken as the 100% value). □, Fos–Jun+TRE; ○, Fos–Ψ-Fos+TRE; ■, Fos–Jun+random oligonucleotide; ▲, Fos–Ψ-Fos+random oligonucleotide.

interactions with antibody αP3. This antibody was directed against amino acids 214–226 of Fos and so was able to recognize the E300 and Ψ-Fos proteins (amino acids 1–316; see Fig. 1) very strongly, but not JR220 (amino acids 1–220; see Fig. 1; Fig. 2, compare lanes 3 and 4). JR220 was precipitated, however, by α455 (lane 1), an antiserum directed against bacterially expressed Fos (see Fig. 1)[12]. When labelled JR220 was incubated with unlabelled E300 and precipitated with αP3 antibodies no complex formation could be detected (Fig. 2; similar background bands in lanes 4 and 5). By contrast, complex formation was observed when labelled JR220 was incubated with Ψ-Fos (Fig. 2, lane 6). It seems that Fos (JR220) and Ψ-Fos associate less efficiently than Fos and Jun (Fig. 2; lane 7), although these results are not easily comparable because of the unavoidable use of different antibodies and *in vitro* translated proteins. These

observations demonstrate that it is the structure of the leucine zipper that normally prevents the formation of Fos homodimers. This may indicate that amino acids other than leucines have a role in the interaction.

The Ψ-Fos protein was then analysed for its ability to bind the TRE as a homodimer or a pseudo-homodimer. The results of the band-shift assay are displayed in Fig. 3*a*: (1) under the conditions used no binding was observed with Fos (lane 6) or Jun (lane 5) alone, but the Fos-Jun complex (lane 1) bound cooperatively as previously reported (lanes 1-3). Under different experimental conditions, that is if the concentration of Jun protein or oligonucleotide probe is increased, it is possible to detect binding of Jun homodimers (ref. 9; also our unpublished observations); (2) the Fos-Ψ-Fos complex efficiently bound to the TRE oligonucleotide; and (3) both the Ψ-Fos homodimer and a Ψ-Fos-Jun heterodimer also bound to the TRE oligonucleotide, but with less affinity than the Fos-Ψ-Fos complex. (The formation of Ψ-Fos-Ψ-Fos and Ψ-Fos-Jun dimers has not been shown in a protein-complex reconstitution assay but is very likely because of the similar migration of the different protein-TRE complexes in the band-shift assay in Fig. 3*a*; that is, the migration in lane 3 is similar to that in lane 5, and that in lane 4 is similar to that in lane 6). The specificity of the binding of Fos-Ψ-Fos to the TRE was analysed in competition experiments using different concentrations of specific or non-specific oligonucleotides (Fig. 3*b*). Whereas no inhibition of binding was seen with the non-specific oligonucleotides, the specific TRE-containing oligonuceotide inhibited the binding of either the Fos-Jun complex or the Fos-Ψ-Fos complex to the TRE in a similar concentration-dependent manner. These results indicate that the Fos-Ψ-Fos complex can bind to the TRE with a relative affinity and specificity comparable to that of the binding of the Fos-Jun complex.

Our results demonstrate that the DNA-binding site of Fos can interact specifically with the TRE provided that a homodimeric complex is formed. It is probable that in the natural Fos-Jun complex the situation is similar. Our observations, therefore, strongly support the hypothesis that Fos and Jun form a nearly symmetrical DNA-binding site in which both proteins recognize similar nucleotides in the TRE. Each protein could thus interact with one half-site of the TRE. There could be at least two different reasons why the Fos-Ψ-Fos dimer binds with lower affinity to the TRE than does the Fos-Jun complex: (1) the association of Fos and Jun may be more stable than the Fos-Ψ-Fos complex as indicated by the results in Fig. 2; (2) the TRE is not perfectly symmetrical; only the seven core-bases form a perfect palindrome, but the sequence interacting with AP1 is longer, as indicated by mutagenesis of the TRE (ref. 20). Therefore, if one half-site of the TRE is preferred by Fos and the other by Jun, one would expect the Fos-Jun complex to show a higher affinity for the TRE than either the Fos-Ψ-Fos complex or the Jun-Jun complex.

The analysis of the interaction of AP1 with the TRE, and *trans*-regulation of AP1-dependent transcription is made complicated by the fact that AP1 is a heterodimer. In this respect the Ψ-Fos described here may prove very useful because it does not require Jun for specific DNA binding. □

Adaptive eradication of methionine and cysteine from cyanobacterial light-harvesting proteins

Didier Mazel & Philippe Marlière*

Unité de Physiologie Microbienne and *Unité de Biochimie Cellulaire, Département de Biochimie et Génétique Moléculaire, Institut Pasteur, 28 rue du Docteur Roux, 75724 Paris Cedex 15, France

SULPHUR is unique among the main elements of living cells in that it is covalently bound to biopolymers but does not occur in the biopolymer backbone. Indeed, most of the bacterial sulphur content resides in the methionine and cysteine side-chains of proteins[1]. The growth yield of an organism under conditions of sulphur limitation could therefore be greatly enhanced by mutations that substitute Met and Cys in the organism's proteins for sulphur-free amino acids. Because the saving in sulphur would increase with such accumulating mutations, Met and Cys changes could be progressively selected. Abundant proteins should be the prime targets of such a selection. A few published observations give credence to this scenario. Sulphate permease, which is abundantly produced by sulphur-starved *Salmonella typhimurium*, lacks Met and Cys residues[2]. Also, two species of marine purple bacteria synthesize more protein than can be expected from a limited sulphate supply[3]. We now report that the cyanobacterium *Calothrix* sp. PCC 7601 (referred to here as *Calothrix*) encodes sulphur-depleted versions of its most abundant proteins—phycocyanin and its auxiliary polypeptides—which it specifically expresses under conditions of sulphur limitation. Although these proteins do not take part in the fixation of sulphur, their elevated synthesis affects the sulphur budget of cyanobacterial cells. Direct evidence is thus provided that the structure of macromolecules can be subject to metabolic optimization.

Phycobilisomes, the light-harvesting complexes of cyanobacteria, account for up to 60% of the soluble protein content in these organisms[4]. The overall design of the phycobilisome consists of a hemidisk of six rods radiating fanwise from a central core[5,6]. Phycobilisomes are made of three principal classes of chromophoric proteins (phycobiliproteins): allophycocyanin (AP) in the core, and phycocyanin (PC) and phycoerythrin (PE) in the rods, all composed of α- and β-subunits. All these chains ultimately derive from a unique common ancestor, structurally similar and evolutionarily related to the globin family[7]. Open tetrapyrrole chromophores (phycobilins) are post-translationally grafted to phylogenetically conserved Cys residues on both subunits[8]. In addition, phycobilisomes contain auxiliary proteins devoid of chromophore, called the linker polypeptides (LP). Three phycocyanin operons have been characterized in *Calothrix*[8]. The operon *cpc1*, which encodes the two PC1 subunits, is expressed regardless of the light spectrum, whereas transcription of the operon *cpc2*, which encodes the two PC2 subunits and their three associated linker polypeptides, is triggered by the red wavelength component[8]. In addition, a third operon, named *cpc3*, whose products had never been

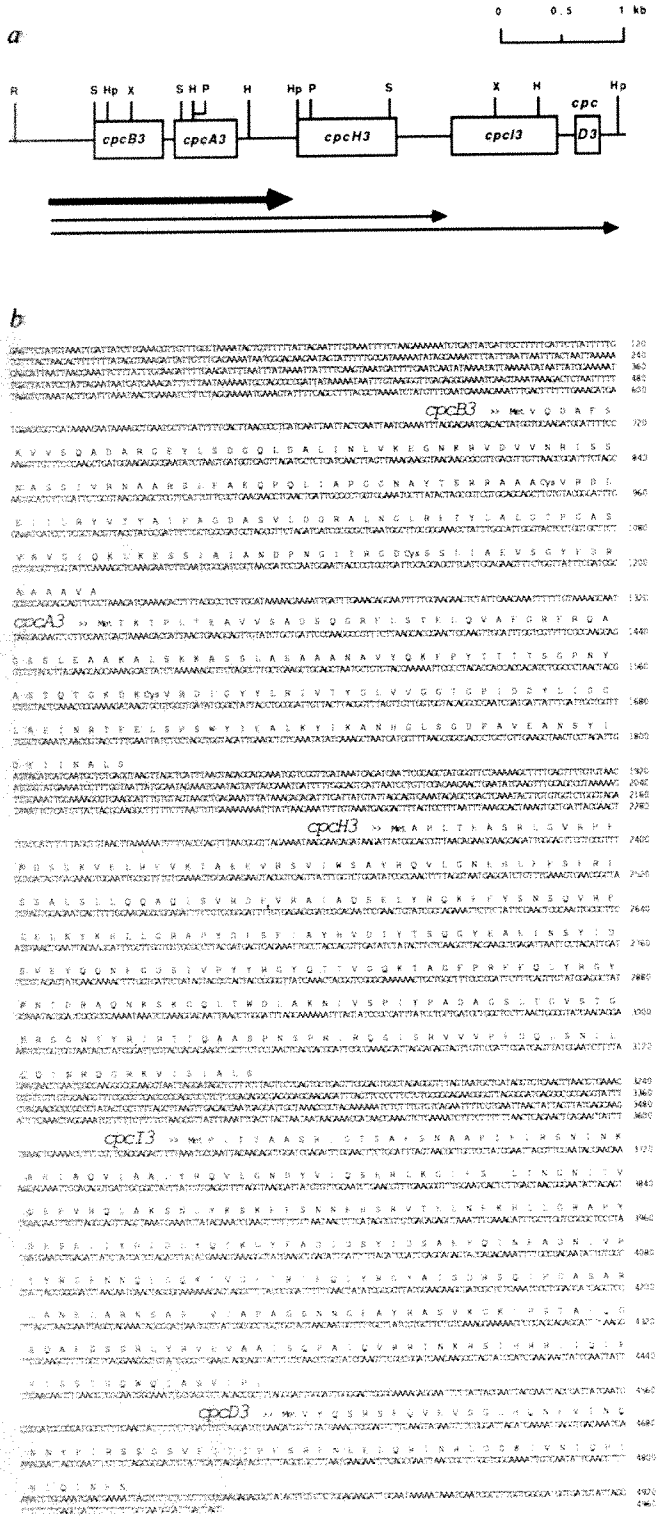

FIG. 1 Physical organization (*a*) and nucleotide sequence (*b*) of the *Calothrix cpc3* operon. *a*, Structural genes are indicated by open boxes and transcripts by arrows (see Fig. 3). Restriction sites are denoted as follows: H, *Hin*dIII; Hp, *Hpa*I; P, *Pst*I; R, *Eco*RI; S, *Sty*I; X, *Xba*I. *b*, Amino acids are denoted by the single letter code except for Met and Cys residues.

METHODS. The molecular cloning of the 9.5-kb *Eco*RI fragment encompassing the *cpc3* locus, and the nucleotide sequencing of the *cpcB3* and *cpcA3* genes have been reported previously[9]. The remainder of the *cpc3* operon sequence was established similarly.

biochemically characterized, is transcribed at a very low level, regardless of the illumination spectrum[9].

The sequence of the *cpc3* locus has now been completed (Fig. 1). It includes five open reading frames highly homologous to, and arranged in the same order as, the five genes of the *cpc2* operon[8]. These putative genes were therefore designated *cpcB3*, *cpcA3*, *cpcH3*, *cpcI3* and *cpcD3*. They are thought to encode the α- and β-subunits of a novel phycocyanin (hereafter designated PC3), and three linker polypeptides, respectively. These five genes, encoding over 1,000 amino acids, share a striking feature which distinguishes them from their counterparts in the operons *cpc1* and *cpc2*: they are free of codons specifying sulphur-containing amino acids, except for the five Met initiation codons and the three Cys codons corresponding to the phycobilin attachment sites (Fig. 2). This observation prompted us to test whether the *cpc3* operon, which remains silent in cells grown under standard conditions, is induced by sulphur deprivation.

Cells of *Calothrix* growing under white light in medium BG-11, containing 300 μM sulphate[10], were collected, washed, starved for 4 days in medium devoid of sulphate, and then inoculated in medium BG-11/S, containing 15 μM sulphate. The brown cells turned green. Spectral analysis of whole-cell extracts revealed the disappearance of the PE absorption peak and a concomitant increase of the PC absorption peak (data not shown). The green cells could be indefinitely subcultured in BG-11/S medium. The change could be reversed by addition of sulphate to the deprived cultures or by subculturing them in fresh BG-11 medium. Messenger RNA hybridization with specific DNA probes showed that transcription of the operons encoding rod components was controlled by the availability of sulphur (Fig. 3). The *cpc3* operon was found to be highly expressed at low concentrations of sulphate in the culture medium. Three different mRNA species could be detected. The most abundant one, about 2-kilobases (kb), corresponded to the co-transcription of *cpcB3* and *cpcA3*, encoding PC3 α- and β-subunits. Two less abundant mRNAs were the 3.3-kb *cpcB3A3H3* and the 5-kb *cpcB3A3H3I3D3* transcripts. By contrast, the expression of the PC1-, PC2- and PE-encoding operons *cpc1*, *cpc2* and *cpe*, respectively, was switched off under conditions of sulphate limitation (Fig. 3). Transcription of the *apc* operon, encoding AP, persisted under these conditions (Fig. 3). Work is in progress to determine the mechanism of the transcription switch. There is no indication of a run of Met or Cys codons suggestive of a sulphur attenuator upstream of the *cpc3* genes.

The synthesis of sulphur-depleted phycobilisome proteins under conditions of sulphate limitation was further assessed by taking advantage of the fact that Met-free proteins, such as the putative *cpc3* gene product should resist cyanogen bromide (CNBr) treatment, whereas proteins encoded by *cpc*1, *cpc2*, *cpe* and *apc* should be cleaved into peptides. As shown in Fig. 4, purified phycobilisomes, or phycobiliproteins, from sulphate-unlimited and -limited cultures of *Calothrix*, which produce similar patterns in polyacrylamide-gradient gel electrophoresis, could indeed be distinguished by CNBr treatment.

That *cpc3*-encoded phycobilisome rods are functional is established by two main observations. Sulphate-limited *Calothrix* cells whose phycobilisomes lack PC1, PC2 and PE grow exponentially under white light, from which they must obtain their energy. Also, emission fluorescence experiments, performed on whole cells grown in sulphate-unlimited or -limited media, showed that light was in both cases efficiently transferred by phycobilisome-bound phycocyanin to the reaction centre of photosystem II (data not shown). In addition, the β-subunit of PC3 was found to bear a post-translationally γ-N-methylated Asn residue at position 72 (Dr A. N. Glazer, personal communication), as do other PC molecules[11].

The amino-acid sequences deduced from the *cpcA3* and *cpcB3* genes protrude by their initiation Met residues when they are aligned to their *cpc1* and *cpc2* counterparts, as if cleavage is required to put them into register (Fig. 2). Furthermore, the

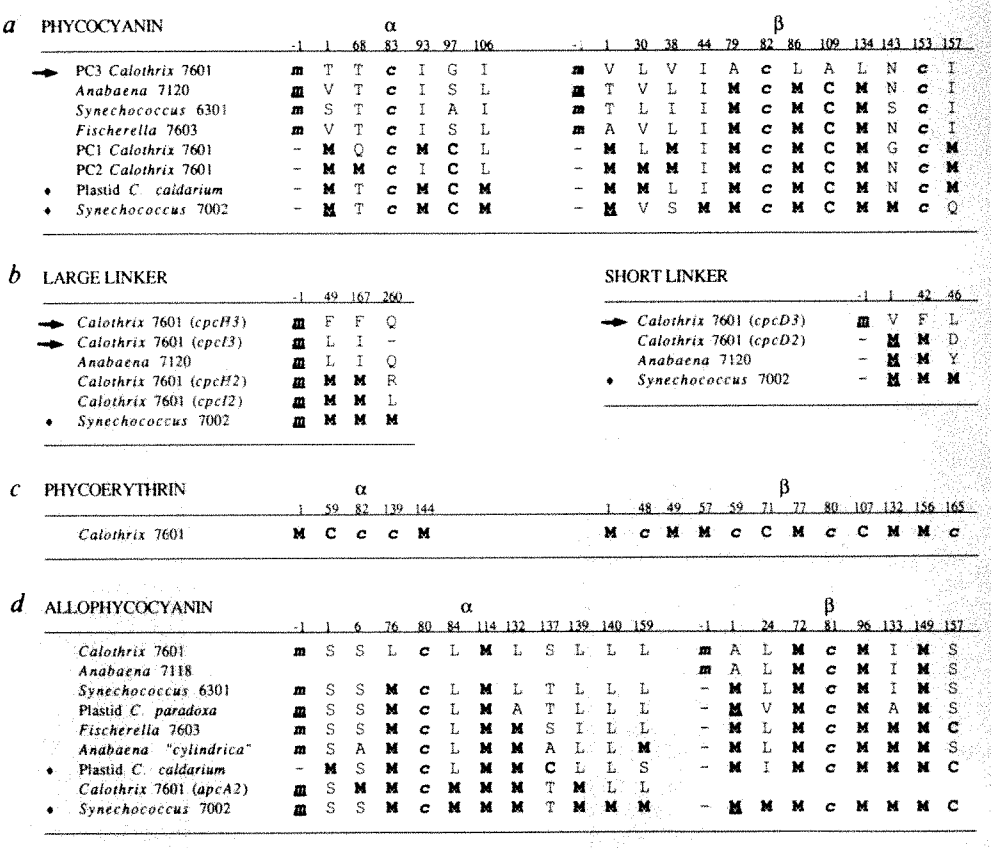

FIG. 2 Pattern of sulphur occurrence in cyanobacterial light-harvesting proteins. Amino acids are denoted by the single-letter code. *a*, Phycocyanin α- and β-subunits[8,21-25]. *b*, Phycocyanin-associated LPs[8,23,25]. *c*, *Calothrix* 7601 phycoerythrin α- and β-subunits[26]. *d*, Allophycocyanin α- and β-subunits (ref. 27). Alignments are compacted to show only positions among all the proteins that contain at least one Met (M) or Cys (C). Amino acids denoted by lower-case italics correspond to post-translationally matured sites, cleavable initation Met[12] or chromophore-bearing Cys[6]. Initiation Met residues whose presence or absence at the N-terminus of mature proteins have not been experimentally proven are underlined. Sequences are listed in order of increasing number of Cys plus Met residues. Position number is indicated above the top sequence of each group. Species numbers correspond to those in the Pasteur Culture Collection of cyanobacteria. Species living in sulphur rich environments are indicated by a diamond, and *cpc3* gene products by an arrow. N-terminal microsequencing showed that PC1- or PC2 α- and β-subunits, PC3 α- and β-subunits, and AP α- and β-subunits start with M-K-T and M-L-D, T-K-T and V-Q-D, and S-I-V and A-Q-D, respectively.
METHODS. N-terminal microsequencing was performed using an Applied Biosystems model 470 A sequencer, on proteins transferred to Immobilon-P membranes after gel electrophoresis[28].

initiation Met residues of the five *cpc3* gene products are followed by residues known to be recognized by methionine aminopeptidase[12]. Determination of the N-terminal sequences of purified PC α- and β-subunits from sulphate-limited and -unlimited cultures, showed that Met was indeed absent and present, respectively, at the beginning of the chains (see Fig. 2 legend). Both the α- and β-subunits of *Calothrix* AP, which are expressed regardless of sulphur availability (Fig. 3), have protruding initiation Met residues when their sequences are aligned to those of other phycobiliproteins (Fig. 2). Again, these residues were found to be cleaved post-translationally (see Fig. 2 legend). Conversely, both PE α- and β-subunits, which are silenced under conditions of sulphur limitation, begin with an unprocessed Met residue[13]. Note that PE has a high sulphur-containing amino-acid content compared to other *Calothrix* phycobiliproteins (Fig. 2*c*). It has been proposed that the susceptibility of proteins to degradation, and hence their cellular lifespan, is governed by the first aminoacid, and that initiation Met cleavage is crucial in this regard[14]. Our data show that sheer economy in Met or sulphur can also be important in the N-terminal maturation of proteins.

As is apparent from Fig. 2*a*, the eight known PC amino-acid sequences from six different cyanobacterial species fall into two clearcut classes that reflect the abundance of sulphur-containing amino-acids. *Calothrix* PC3 has the fewest sulphur-containing amino acids. Rod LPs closely follow the pattern of their corresponding PCs (Fig. 2*b*). The sulphur-containing amino acid distribution in the sequences of AP also matches that of PC but with less contrast (Fig. 2*d*). The consistent partition of PC and AP sequences into sulphur-rich and sulphur-depleted classes does not correspond to a phylogenetic dichotomy in the cyanobacterial lineage[15,16]. It does, however, fit the available ecological data. Indeed, the two organisms with the PC and AP richest in sulphur, *Synechococcus* 7002 and *Cyanidium caldarium*, were isolated from habitats with a large excess of sulphate, sea water[10] and acidic hot springs[17], respectively. Conversely, organisms with sulphur-depleted PC and AP are found in low sulphate environments: *Calothrix* 7601, *Anabaena* 7120, *Cyanophora paradoxa* and *Synechococcus* 6301 in freshwaters[10], and *Fischerella* 7603 in alkaline geothermal streams[18]. Phycobiliprotein sequences thus provide geochemical records of their evolutionary environments.

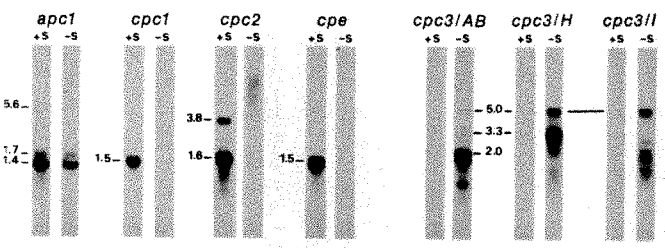

FIG. 3 Northern analysis of the mRNAs transcribed from *Calothrix* light-harvesting operons, that is, *apc* (AP), *cpc1* (PC1), *cpc2* (PC2), *cpe* (PE) and *cpc3* (PC3). Total RNA extracted from *Calothrix* cells grown in standard BG11 medium (+S) or sulphur limiting BG11/S medium (−S) (see text) were hybridized with: a 303 bp *DraI*–*HincII* fragment covering the 5′ extremities of the *apc* transcripts (panel *apc*); a 1-kb *HindIII* fragment covering *cpcB1* and the 5′ end of *cpcA1* (panel *Cpc1*); an 836-bp *ClaI*–*XbaI* fragment covering the *cpcB2* 3′ end and the 5′ end of *cpcA2* (panel *ccpc2*); a 292-bp *HindIII* fragment covering the *cpcB* 3′ end and the 5′ end of *cpeA* (panel *cpe*); a 463-bp *XbaI*–*HindIII* fragment covering the *cpcB3* 3′ end and the *cpcA3* 5′ end (panel *cpc3/AB*); an 859-bp *HindII* fragment almost completely encompassing *cpcH3* (panel *cpc3/H*); and a 342-bp *XbaI*–*HindIII* fragment internal to *cpcI3* (panel *cpc3/I*). Transcript sizes are in kilobases.
METHODS. Total RNA extractions were as previously described[26]. Northern transfers and hybridizations were performed as in ref. 9.

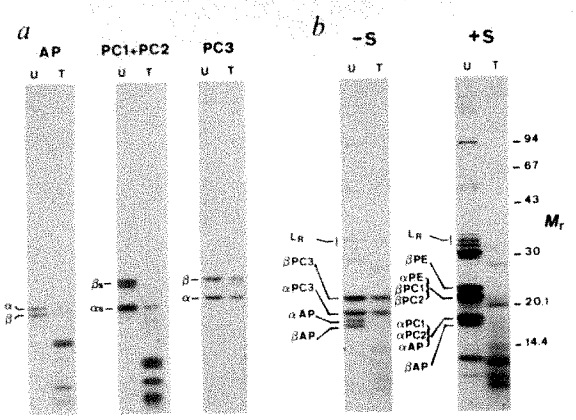

FIG. 4 Screening of Met-depleted phycobilisome proteins. U corresponds to crude samples and T to CNBr treated samples. *a*, Purified phycobiliproteins. *b*, Purified phycobilisomes from sulphate-limited (−S) and unlimited (+S) *Calothrix* cultures. L_R, rod linker polypeptides. M_r, relative molecular mass. METHODS. Purification of phycobiliproteins and phycobilisomes were carried out as previously described[29,30]. The procedures for CNBr cleavage, and for electrophoresis and Coomassie blue staining of SDS 10–20% polyacrylamide gradient gels were as in refs. 31 and 30, respectively.

The constraints governing the folding, activity, specificity and stability of proteins are presumed to have shaped protein molecules during evolution[19]. Eradication of Met and Cys residues from phycobiliproteins indicates that economical constraints also came into play. That most microorganisms experience prolonged starvation in natural environments[4,20] further suggests that the metabolic design of macromolecules is not an epiphenomenon, and raises two questions. First, to what degree could the elimination of an amino acid be extended in an organism? Second, are methionine and cysteine predisposed to disuse, or could this also be the fate of other amino acids? If so, changes in homologous proteins that seem functionally neutral may need to be reappraised in terms of the metabolic cost and availability of amino acids. □

Fitness reduction associated with the deletion of a satellite DNA array

Chung-I Wu, John R. True & Norman Johnson

Department of Biology, University of Rochester, Rochester, New York 14627, USA

SATELLITE DNA refers to a class of tandem repeats of very simple sequences, usually A+T or G+C rich, which form a satellite band on a CsCl gradient. Their ubiquity and abundance in higher eukaryotes have led to speculation about their functions[1–3]. It has often been suggested that satellite DNAs are merely innocuous genetic parasites or comprise 'junk' DNA[2–4]. The recent identification of an array of satellite DNA repeats as the *Responder* (*Rsp*) locus of *Drosophila melanogaster* provides a new perspective on these elements[5]. *Rsp* is in the centromeric heterochromatin of most natural second chromosomes[6]. It causes spermatids bearing it to degenerate after meiosis when the homologous second chromosome is a *Segregation Distorter* (*SD*) chromosome. That is, *SD* targets the *Rsp* locus on its homologue for destruction during spermatogenesis, causing meiotic drive. Why then does the *Rsp* locus, a large array of satellite repeats, exist at all? One plausible explanation is that its existence contributes to the fitness of flies bearing it, compensating for the loss through meiotic drive. A direct demonstration of the usefulness of any family of satellite DNA is to compare the fitnesses of individuals with and without it. Previously, such an experiment has been difficult because the absence of a characteristic phenotype has precluded an efficient selection of deletion mutations. In this report we attempt to demonstrate a fitness reduction associated with the deletion of *Rsp* satellite DNA as well as the life stages at which such a reduction occurs.

The *Rsp* locus has been deleted from chromosomes and some deletion homozygotes found to be viable and fully fertile[6]. Deletion chromosomes no longer respond to the distorting action of *SD*, indicating the neomorphic nature of *Rsp*. In our experiments, we measured fitness differences between a deletion chromosome, called R16 (*cinnabar brown*^{R16}), and the chromosome from which it was derived, called CB (*cinnabar brown*)[6]. These two chromosomes differ in the amount of *Rsp* satellite repeats that they carry (20 and 700 copies, respectively[5]) but are otherwise genetically identical. Cytological examination indicates that the deletion on R16 is small and is coextensive with the *Rsp* region[7]. Because any *SD* chromosome would induce degeneracy of spermatids bearing the *Rsp* locus, *SD*/CB males transmit only 1% of CB-bearing sperm whereas *SD*/R16 males transmit 50% of R16 bearing ones[6].

Our first experiment demonstrated that *Rsp* satellite DNA can be a liability to chromosomes bearing it when the population also contains *SD* chromosomes, as most natural populations do. Figure 1 shows that the frequency of R16/R16 individuals, relative to the individuals bearing CB, rose sharply from 0.06 to 0.41 in only five generations. The observation is as expected, because *SD* chromosomes should prevent the transmission of CB chromosomes but not of R16 chromosomes in heterozygous males. The identification of genotypes was aided by a quick DNA hybridization procedure that permitted scoring several hundred flies at once. Squash blots of R16/R16 flies (top row of the inset, Fig. 1) indeed failed to hybridize detectably to the *Rsp* probe, which hybridized strongly to squash blots of CB/R16 flies (bottom row).

If such deletions are so advantageous in the presence of *SD* chromosomes why in nature don't these deletion chromosomes replace chromosomes bearing *Rsp*? The frequency of *SD* is ~3% in most populations[8]. Such a worldwide distribution should be sufficient to cause deletions of *Rsp* to become fixed

in natural populations[8,9]. Previous surveys, however, showed that chromosomes deficient in *Rsp* are relatively uncommon[10,11]. A logical deduction is that *Rsp* satellite DNA has a fitness advantage that compensates for the loss in fitness incurred through meiotic drive. In our second experiment, we let CB chromosomes compete with R16 chromosomes in the absence of *SD* chromosomes. Because selection against the R16 deletion, if present at all, was expected to be weak, long-term population cages were set up. To counter an increase in gene frequency variance due to genetic drift, we maintained large populations throughout the course of the experiment.

Figure 2*a*,*b* shows the changes in the frequency of R16/R16 individuals in two cages; with time R16 flies steadily decreased in frequency in both cages. Note that the time scale in these figures is five times that in Fig. 1. There were five measurements from cage 1 and four measurements from cage 2. The frequency of R16/R16 flies decreased between all successive measurements ($P = 0.5^7 < 0.01$). Curve fittings of observed changes to theoretical trajectories based on the standard selection formula[12] yielded a selection coefficient of 0.008 and 0.012 per day for the two cages, respectively. The experiment, therefore, demonstrates the fitness contribution of *Rsp* satellite DNA to be about 13–19% per generation. Dominance in this range of gene frequency (0.35–0.61) does not change the theoretical trajectory appreciably although the best fit on data from either cage is obtained when the CB chromosome is assumed to be dominant. We have therefore studied the fitness differences between CB/R16 individuals and R16/R16 individuals in greater detail.

At what life stages does the *Rsp* satellite DNA exert its fitness effect? We thought that the stage of male fertility was the most probable for several reasons. First, the 'negative phenotype' of *Rsp* satellite DNA, namely *Segregation Distortion*, is manifested during spermatogenesis. Second, the male fertility component of fitness is important in *Drosophila*, especially in meiotic drive systems[13]. Third, it has been proposed that satellite DNAs function primarily in germ cells[2]. Table 1 presents some surprising results. Males homozygous for R16, with little *Rsp* satellite DNA, were as fertile as CB/R16 males. Because *Drosophila*

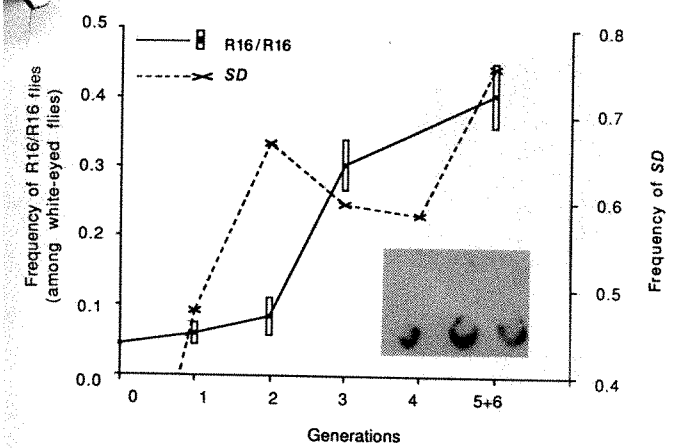

FIG. 1 Changes in the frequency of R16/R16 flies among white-eyed flies (CB/CB, CB/R16 and R16/R16) in the presence of *SD*.

METHODS. Both CB and R16 carry *cinnabar* (*cn*) and *brown* (*bw*) recessive mutations, and homozygotes of double mutations are white eyed. The *SD* chromosome used is SD_{MAD}, which carries inversions that suppress recombination between the *Rsp* locus, *cn* and *bw*. During the experiment, recombination between *cn* and *bw* was not observed. The experiment was started with 250 pairs of flies with the following composition: *SD*/*SD* (4.7%), *SD*/CB (13.8%), CB/CB (68.7%), CB/R16 (8.4%) and R16/R16 (4.4%), close to the Hardy–Weinberg ratio. The last three types are white eyed. The experiment was of a discrete-generation design conducted in a big cage at 25 °C. In each generation, adults were allowed to lay eggs on fresh food for 6–8 days and then sorted according to eye colour and sex. White-eyed flies were stored at −70 °C for genotype identification by squash-blotting. The bottles containing larvae were left in the cage for the emergence of the next generation. Newly emerged flies were allowed to mate without any handling. Six new bottles were put in to start the next generation two days after the first adult emerged. The change in the frequency of the *SD* chromosome was reflected in the proportion of red-eyed flies. The more *SD* chromosomes present, the greater the disadvantage of CB relative to R16. Whereas R16 had been steadily replacing CB, the largest increase took place between generations three and four, immediately after the largest increase in *SD* in previous generation. The frequency of *SD* is given as $1 - w^{0.5}$, where w is the proportion of white-eyed flies in the total. Genotypes of white-eyed flies were determined by squash-blotting adult flies on nitrocellulose paper, which was then soaked in 2% SDS before being placed on denaturing and neutralizing buffer. Hybridization was in the presence of the *Rsp* satellite DNA probe. The results are shown in the inset. Top row, R16/R16 flies; bottom row, R16/CB flies.

TABLE 1 Measurement of fitness components

Fertility

	Males	Females
CB/R16	98.0 ± 4.86 (21)	72.3 ± 3.35 (28)
R16/R16	103.1 ± 6.57 (17)	63.0 ± 6.44 (11)

Viability of R16/R16 relative to CB/R16

	Males	Females	Total
Cross I	—	—	0.650 ± 0.078 (297)
Cross II	0.564 ± 0.087 (183)	0.681 ± 0.099 (195)	0.622 ± 0.066 (378)

Developmental time

	Proportion of R16/R16 flies that emerged on:		
	day 10	day 11	days 12–15
	0.201 ± 0.034 (139)	0.200 ± 0.037 (120)	0.145 ± 0.042 (69)

Numbers in parentheses are sample sizes. Virgin females are referred to as females. Flies used for the fertility tests were the F_2 resulting from the following crosses: CB/CB females × R16/R16 males (P); R16/R16 females × CB/R16 males from P (F_1). The F_2 individuals were either CB/R16 or R16/R16. Identification of genotypes was done after the fertility tests were completed by squash-blotting. The scheme ensured an identical culture and genetic background, which was identical between the two parental stocks. Male fertility: Each freshly emerged male was mated to three CB/CB females (4 days old) for three days and then transferred to a new vial containing three more females for three more days. The first trio were also transferred to new yeasted medium for further egg-laying. Progeny from all three vials were counted and added. Each male was thus mated to six females with each female allowed a six-day egg-laying period. Because a fully inseminated CB/CB female in a six-day period can produce more than 50 progeny, the male fertility test was carried out under a sperm-limiting condition. Female fertility: Each female was 2-days old before being given three CB/CB males (4-days old) and allowed to lay eggs for 8 days in the presence of the males. Egg production is the limiting factor in the female fertility test. Viabilities: random sample of F_2 individuals from each of the two crosses were squash-blotted. Cross I: R16/R16 females × CB/CB males (P); R16/R16 females × CB/R16 males from P (F_1). Cross II was identical except that the P generation was CB/CB females × R16/R16 males. The ratio of the two genotypes in F_2 CB/R16 and R16/R16, was expected to be 1 in the absence of any viability difference. An unbiased estimator of the relative viability (v) and its variance are used. [$v = x/(y+1)$ and $\sigma^2 = v(1+v)^2/(x+y)$, where x is the number of R16/R16 flies and y is the number of CB/R16 flies[27].] In Cross I, the sex of F_2 individuals was not distinguished. Developmental time: well-yeasted food bottles were placed into Cage I (Fig. 2) for 4 h to collect eggs. The bottles were then cleared of adults, capped (to prevent further egg laying) and returned to the cage until the emergence of adults 10 days later. The proportion of R16/R16 flies in each day's sample was then determined.

males usually ejaculate more sperm than females can utilize[14], males suffering some extent of spermatogenic failure may have appeared as fertile as normal males if the experiment had not been done under sperm-exhaustion conditions[13-15]. To ensure the detection of spermatogenic differences, very young males can be used[14,15], or many females supplied, or pre-inseminated females can be mated for detecting sperm displacement[13]. We used a combination of the first two tactics. The total productivity was limited by the supply of sperm because females under the same condition would have been much more fecund if more males were available (see Fig. 2 legend). The absence of an observable difference in male fertility suggests that *Rsp* satellite DNA has little or no role during normal spermatogenesis and, whatever the normal function of *Rsp* satellite DNA, it is distinct from the event of segregation distortion. The fertility difference in females is statistically insignificant ($P > 0.1$).

Despite the lack of observable fertility differences due to the presence of *Rsp* satellite DNA, large differences in viability could be detected, as shown in Table 1. The experiment, repeated with the reciprocal cross, yielded nearly identical results. The viability effect seemed to be independent of sex. The large difference in viability was higher than the measurement taken from the population cages, where total selection per generation is estimated to be ~0.15. The discrepancy was due primarily to the measurement of individual fitness components (viability and fertility) under more severe conditions than in the long-term cages. Fertility was measured under sperm and egg exhaustion conditions, and egg-to-adult viability for all genotypes was appreciably lower than that in the optimal cultures. The important point is that no fertility differences could be detected whereas large viability differences were observable under stringent conditions. Finally, we measured the relative developmental time by counting the proportion of R16/R16 individuals among the total in the sequential samples. The proportion remained nearly constant during the first two days. During the subsequent four days, the proportion of R16/R16 individuals actually decreased although this decrease is statistically insignificant and can be best attributed to a small sample size. Within the resolution of our measurement, we conclude that R16/R16 flies do not develop more slowly than the other two types.

There are several explanations for the observed fitness deficiency of the R16 deletion chromosome, relative to the original CB chromosome. We can rule out deleterious mutations in the background (X, Y or the third chromosomes) because CB and R16 stocks had been mixed for five generations before the first measurement was taken (see fig. legends). The continual decline of R16 chromosomes in the ensuing nine months also supports this point. There is a formal possibility that the reduced fitness of R16 was due to a deleterious mutation of R16. Such a mutation would have had to be sufficiently close to *Rsp* to be consistent with the steady decline of R16 but should have been outside of the R16 deletion for two reasons. First, Pimpinelli and Dimitri[7] have shown cytologically that the deletion does not extend beyond the region occupied by the *Rsp* repeats. The R16 deletion is indeed much smaller than heterochromatic deletions or duplications used in previous studies[2,16] and genes in 2R heterochromatin are all mapped some distance away from this deletion[7,17]. Second, there is no evidence for single-copy sequences within the region of *Rsp* repeats. From a lamda library and a cosmid library, we have obtained many different clones in the *Rsp* region. These clones showed only dispersed repetitive sequences adjacent to *Rsp* repeats. The interspersed repetitive sequences within the R16 deletion are not likely to account for the observed fitness differences of R16 because there are many more of these dispersed sequences outside of the R16 deletion than within it. Our observations, therefore, are best explained by the deletion of *Rsp* repeats although we cannot completely rule out the existence of an unidentified, but closely-linked secondary lesion, induced by the same irradiation that deleted

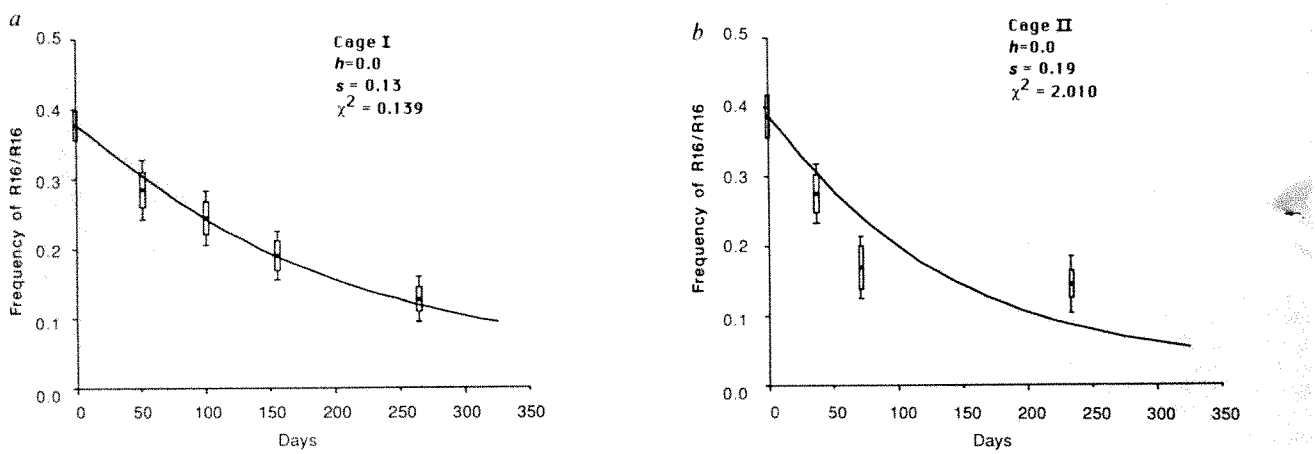

FIG. 2 *a*, *b*, Changes in the frequency of R16/R16 flies in the absence of *SD*. METHODS. Each cage was started with ~300 pairs of flies, 40% R16/R16 and 60% CB/CB. The populations were then allowed to expand to 3,000–5,000 flies. The first sampling, day 0 in the figure, was done 8-weeks later. Although the two stocks were genetically identical when constructed[7], such a shuffling period allowed further randomization of the genetic background. The populations were maintained at 25 °C with overlapping generations, and the population sizes never dropped below 3,000. Sampling were done every 50 days or so by collecting all flies that emerged from several food bottles. All samples consisted of 200–400 flies, squashed-blotted for genotype determination. The binomial sampling standard errors are indicated by the thick bar. The stochastic standard errors due to genetic drift are represented by the thin bar. Stochastic variances are calculated by $V_t = p(1-p)(1-e^{-t/2N})$ (ref. 12), where p is the frequency of R16, t is the number of generations between two successive data points and N is the effective population size. N is assumed to be 2,000 (~70% of the minimum of the actual number). A least-square fitting of observations to theoretical calculations was carried out. Theoretical values were obtained using the formula, $\Delta q = -spq[q + h(p-q)]/(1-2pqhs-q^2s)$, where s is the coefficient of selection against R16, h is the degree of dominance, q is the frequency of R16, and $p = 1-q$. A series of s and h values were used to find the combination that minimized χ^2, (observed − expected)^2/expected, summed over all data points. The expected frequency of R16/R16 in each generation was calculated as $q^2(1-s)/(1-2pqhs-q^2s)$. The calculation assumes only pre-adult selection, which is supported by the data of Table 1. The generation time, the average age of mothers of sampled offspring, was assumed to be 16 days. (The mean emergence time was 11 days and we assumed the generation time was five days after emergence.) The best fit is given in the figure.

Rsp repeats. It is worth noting that there is a paucity of genes in centromeric heterochromatin.

The prevailing view that satellite DNA is mostly 'junk'[2–4,18], whose presence or absence has no bearing on the fitness of its carriers, has been widely accepted. Most of the support for this came from interspecific comparisons[2,18]. By adding extra heterochromatic materials or by deleting nearby essential (ribosomal RNA) genes, previous studies[2,16] only addressed the issue indirectly. We have provided the first direct test of this hypothesis by comparing the fitnesses of *Drosophila* with, and without, a well characterized array of satellite repeats. A fitness effect is clearly detectable. The observed effect is also inconsistent with the view that the functions of satellite DNA, if any, must be in the germ cells[2].

It is premature to generalize our conclusion to other satellite DNAs. After all, *Rsp* was identified because of segregation distortion. Nevertheless, our results show that this negative phenotype (in germ cells) can be uncoupled from its positive functions (in the soma). It is possible that other satellite DNAs perform similar positive functions without the dramatic negative phenotype associated with *Rsp*. *Rsp* satellite DNA has a marked sequence-directed curvature (that is, DNA bending; unpublished results), which is often associated with A+T-rich DNAs such as mouse satellite DNA[19]. Bent DNA is important in nucleosome assembly[20] and chromatin condensation[19]—it should be noted that segregation distortion results from aberrant chromatin condensation in spermatids bearing *Rsp*[21]. Parallel systems involving heterochromatic materials, such as Sex-Ratio distortion[22] or B chromosome segregation[23] may be a logical next step for investigation. Attempts to define the genetic roles of heterochromatic materials, such as Position Effect Variegation[24], and to identify satellite-DNA-specific binding proteins[25,26] are clearly promising approaches. It is far fetched to think all satellite DNAs have a useful role, but it is equally unwise to label them universally as junk in the absence of any other direct proof. □

Functional replacement of a protein-induced bend in a DNA recombination site

Steven D. Goodman & Howard A. Nash

Laboratory of Molecular Biology, National Institute of Mental Health, Bethesda, Maryland 20892, USA

In recent years the capacity of proteins to bend DNA by binding to specific sites has become a widely appreciated phenomenon[1–7]. In many cases, the protein-DNA interaction is known to be functionally significant because destruction of the DNA site or the protein itself results in an altered phenotype. An important question to be answered in these cases is whether bending of DNA is important *per se* or is merely a consequence of the way a particular protein binds to DNA. Here we report direct evidence from the bacteriophage lambda integration system that a bend introduced by a protein is intrinsically important. We find that a binding site for a specific recombination protein known to bend DNA can be successfully replaced by two other modules that also bend DNA; related modules that fail to bend DNA are ineffective.

Bacteriophage λ requires two DNA binding proteins, Int and integration host factor (IHF), to integrate site-specifically into the *Escherichia coli* chromosome[8]. Although it is known that Int, a phage-encoded protein, performs the actual DNA-strand exchanges, the function of the *E. coli* protein, IHF, is less well understood. IHF is a heterodimeric protein with a relative molecular mass of ~20K which binds specifically to three sites within the phage λ recombination locus, *attP*. Mutational analysis of these sites indicate that all three are required for efficient recombination[9] and IHF is known to bend DNA on binding to each of its sites within *attP* (refs 10,11). Many experiments indicate that the active form of *attP* is a condensed nucleoprotein structure, the intasome, in which Int protomers, bound at sites 100–200 base pairs (bp) apart, interact with one another[12]. Experiments in our laboratory have shown that IHF is necessary for intasome formation[13]. IHF could assist the intasome by participating in a network of protein–protein interactions with other protomers of IHF and/or with Int. Another possibility is that, by changing the shape of DNA, IHF could facilitate the interaction of other components of the intasome. In this case, it is the conformation of DNA produced by IHF that is critical for efficient recombination and not the protein itself. We have now tested whether bending is sufficient for IHF function in recombination.

We reasoned that if changing the shape of DNA was the primary function of IHF, we should be able to replace the protein by unrelated elements that also bend DNA. Our initial approach has been to focus on just one of the three IHF binding sites within *attP*, the central or H2 site. The cyclic AMP receptor protein (CRP) of *E. coli* was chosen for the replacement because it is apparently unrelated to IHF in amino-acid sequence and structure but, like IHF (refs 11, 14), is believed to bend DNA sharply, by more than 90° (ref. 15). Our approach in replacing an IHF site of *attP* with a CRP site took into account the expectation that the precise parameters of the two protein-induced bends are not identical. We hoped that inserts of different lengths and orientations might compensate for such differences as well as differences in the size and shape of IHF as compared with CRP. Our strategy for incorporating the CRP binding site into *attP* is shown in Fig. 1. A 38 bp fragment

containing the *lac* CRP site was cloned between tandemly repeated polylinkers. Restriction-endonuclease digestion with different pairs of enzymes created a collection of fragments, all of which had the same CRP site but differed from each other by variable lengths of spacer DNA on either end. These fragments were ligated into a gap in *attP* created by the deletion of the H2 site. Individual chimaeric *attP* sequences (*attP*-CRP) were assayed *in vitro* for integrative recombination with purified IHF and Int in the absence or presence of CRP (gift from J. Harman). Table 1 summarizes our results. In the absence of CRP, no *attP*-CRP chimaera recombines better than the control plasmid with the H2 site destroyed by base substitution[9]. In the presence of CRP, however, several chimaeras yield significant recombination and one, pHN1030, functions almost half as well as a wild-type *attP*. Since all chimaeras contain a CRP site, differences in efficiency probably reflect requirements for inserts with proper spacing and/or helical phasing. This can be seen most clearly when pairs that differ by a 4 bp alteration at a restriction site (for example pHN1030 and pHN1011) are compared. Several additional experiments (not shown) indicate that the chimaeras, as typified by pHN 1030, resemble wild-type *attP* in recombination properties. First, the products of recombination with chimaeras have the expected restriction map. Second, the time course of recombination with chimaeras parallels that of *attP*, being approximately linear under our conditions. Third, recombination of the chimaeras depends strongly on supercoiling, as does that of *attP*. It should also be noted that CRP fails to stimulate recombination of pHN 1030 in the absence of cAMP.

TABLE 1 Recombination of *attP*-CRP plasmids

attP plasmid No.	Insert size* (bp)	Orientation†	Distance from arm to bend centre‡	Distance from core to bend centre§	Recombination (% wild type) −CRP	+CRP
pHN986	74	NA	NA	NA	(100)	102
pHN1006	74	NA	NA	NA	5.9	4.9
pHN1030	126	−	74 bp	52 bp	2.5	41
pHN1031	103	+	52 bp	51 bp	2.4	30
pHN1014	109	+	69 bp	40 bp	1.2	15
pHN1010	88	+	48 bp	40 bp	0.9	11
pHN1008	146	+	64 bp	82 bp	0.6	11
pHN1011	122	−	74 bp	48 bp	1.3	9
pHN1013	99	+	48 bp	51 bp	1.2	6.7
pHN1007	87	−	51 bp	36 bp	<0.1	0.6
pHN1009	94	+	36 bp	58 bp	<0.1	<0.1
pHN1012	94	−	46 bp	48 bp	<0.1	<0.1

Plasmids above the dotted line are controls. pHN986 is wild type, pHN1006 contains a 4 base change introduced into the H2 site which inactivates IHF binding[9]. Plasmids below the dotted line are *attP*-CRP chimaeras. Recombination reactions were performed as stated in Fig. 2 except that cAMP (25 μM) was added to each reaction and CRP (250–500 nM) was added where indicated. pHN986 was tested 22 times; the mean value for recombination in the absence of CRP was 40% (with a range of 11–67%). All other data on the extent of recombination were expressed relative to this value. In 14 tests, the range of relative recombination values for plasmid pHN1006 was 0.2–18% in the absence of CRP and 2–16% in the presence of CRP. For the plasmid pHN1030 (24 tests) the ranges were 0.1–5.5% and 14–85% in the absence and presence of CRP respectively. NA, not applicable.

* The size of the inserted fragment at the original *Nde*I and *Sph*I site of pHN986.

† An arbitrary convention to establish the orientation of the CRP site. + signifies the strand listed for CRP in the legend of Fig. 1 is contiguous with the 'top' strand of *attP*; −, is the opposite orientation.

‡ The number of base pairs from the putative bend centre[16] in the insert to the *Nde*I site.

§, The number of base pairs from the putative bend centre in the insert to the *Sph*I site.

Although the success of the replacement of IHF at H2 by CRP argues strongly for the role of DNA bending as the critical function of IHF, we cannot rule out the possibility that CRP also participates in a network of protein-protein interactions. We think this is unlikely because CRP is apparently unrelated to IHF in primary sequence and overall structure. Nevertheless, to eliminate this possibility more conclusively we have extended our 'bend swap' experiments by replacing the H2 site with DNA that does not depend on protein to create a bend. For this we used a segment of DNA that contains 6 repeats of a tract of 6 adenines phased so as to form a stable bend of ~120° (sequence A_6-1/1; ref. 16, gift from S. Zinkel). We repeated the cloning protocol of Fig. 1 using the 'A tract' DNA instead of the CRP binding site. The 'A tract' was liberated from the vector by cutting within the polylinker as before, and a population of fragments containing a stable bend was then cloned into plasmid pHN986 in place of the H2 locus. The collection of chimaeras (*att*P-K) were then used as substrates for *in vitro* recombination. The results of a representative group of reactions can be seen in Fig. 2. As was observed with the *att*P-CRP chimaeras, there is a wide range in the amount of recombination observed with *att*P-K plasmids. One chimaera (pHN1045, lane 4) recombines at 50–60% of the level of wild-type *att*P. Addition of 4 bp to this chimaera greatly decreases its efficiency (pHN1050, lane 9) as does recloning of the insert in the opposite orientation (pHN1052, lane 11). This shows that in addition to the presence of the sequence-directed bend, spacing and/or phasing of the bend is critical. The importance of the bend is highlighted by our construction of a chimaera that has an insert (the *Taq*I 44667–44809 fragment of λ) of precisely the same length and base composition as the insert in plasmid pHN1045 but which has DNA of normal electrophoretic mobility on a native polyacrylamide gel; this chimaera (pHN1053) produces few or no *in vitro* recombinants (see Table 2). In addition, just as with *att*P-CRPs, *att*P-Ks have an approximately linear rate of recombination and a strong requirement for supercoiling (data not shown). We also asked if the *att*P-K chimaeras were active during *in vivo* site-specific recombination. In a recent study in which the CRP binding site of the *gal* promoter was replaced by a sequence directed bend, a marked discrepancy was noted between *in vivo* transcription and that in a purified *in vitro* system (H. Buc, personal communication.). However, for each *att*P-K tested (Table 2), the amount of *in vivo* recombination relative to wild type *att*P agrees with that expected from its *in vitro* performance.

We have now successfully employed three types of sequences at the H2 locus; the natural IHF binding site, 'A-tract' DNA and a CRP binding site. The pattern of our success allows two conclusions to be drawn. First, the fact that the segments have very different lengths demonstrates that *att*P has a suprising tolerance for spacing between its component parts. Second, the fact that the segments are unrelated except for adopting a bent conformation provides compelling evidence that the role of IHF at H2 is merely to bend DNA and that IHF function at H2 does not depend on protein–protein interactions. We have performed two additional experiments that support this interpretation. First, we assayed for IHF binding to the inserts used in the chimaeras. Because these inserts did not contain an IHF consensus sequence[17], we did not expect binding but we wondered if bending by CRP or the 'A-tract' would relieve IHF of its sequence specificity. If this were the case, our conclusion would be unfounded. To test for IHF binding we incubated the inserts (~300 bp fragments of pBend-CRP or pHN1036) with IHF and/or CRP, and electrophoresed the mixture in a native acrylamide gel; no effect of IHF on the mobility of the fragments was seen. To rule out the possibility that IHF bound to these fragments, but did not shift their mobility, we probed a transfer of the gel with antibody directed against IHF. No IHF was seen in association with the fragments, although control experiments using the H1 site of *att*P or a weaker IHF site found at the

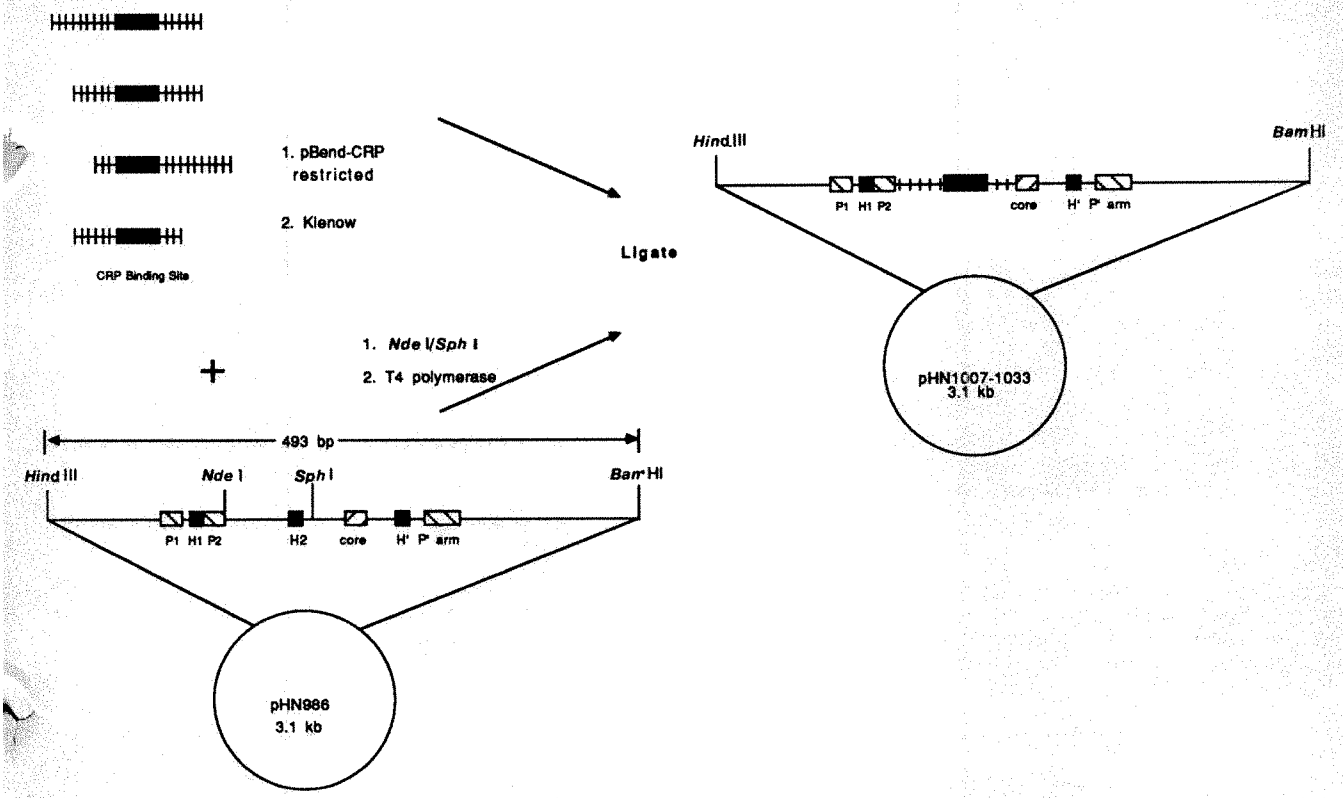

FIG. 1 Construction of chimaeras. Fragments containing a CRP site flanked by variable lengths of spacer DNA were generated by restriction of pBend-CRP, a plasmid in which the CRP site of the *lac* operon (black rectangle) is flanked by tandem repeats of a polylinker (individual sites represented by vertical hatch marks). These fragments, which have a size range from 64 to 106 bp, were used as substitutes for the 75 bp *Sph*I(−23) to *Nde*I (−98) segment of *att*P. Individual *att*P chimaeras (pHN1007–pHN1015) were isolated and sequenced. In addition to finding simple CRP inserts, some chimaeras contain an expected insert plus short stretches of DNA from the tandem repeats (a consequence of not purifying the population of inserts before ligation). From sequenced chimaeras additional clones (pHN1026–pHN1033) were generated by filling in a unique restriction site in the vicinity of the CRP binding site. In each case 4 bp were added to one side or the other of the CRP-site, increasing the distance of this site from either the core or the left side of *att*P.
METHODS. pBend1 and pBend-CRP were the gift of S. Adhya and J. Kim. pBend1 contains tandem direct repeats of 8 contiguous restriction sites (5′-ACGCGTAGATCTGCTAGCATCGATCCATGGACTAGTCTCGAGGGATCC-3′) separated by a single *Xba*I and *Sal*I site (see ref. 7 for a related construction). This cassette was cloned between the *Eco*RI-*Hin*dIII sites of a derivative of pBR322 that had been deleted for the 1.9 kb *Eco*RV to *Pvu*II segment. pBend-CRP was constructed by ligating a 38 bp fragment containing the *lac*CRP site (5′-AATTGCAAT**TAATGTGAGTTAGCTCACTCA**TTAGACCC-3′; the underlined portion is the -77 to -42 region of the *lac* operon; the sequence in bold lettering is the CRP-binding site) into the blunt ended *Xba* I site of pBend1. pHN986 was made by ligating the large *Nde*I–*Dra*I fragment of pUC-4K (ref. 21) to the *Hin*dIII–*Bam*HI fragment from phage λ that contains *att*P (coordinates 27,479–27,972). The *att*P segment came from pCB21 (ref. 22) and has an artificial *Sph*I site which is phenotypically silent for recombination. pHN1006 is identical to pHN986 except that it does not contain the *Sph*I site and there is a 4 bp change in the H2 IHF site which inactivates IHF binding[9]. The complete sequence of the *att*P region of the chimaeric plasmids is available upon request.

boundary of IS1 (ref. 17) gave readily detectable signals (data not shown). In a second series of experiments we determined that the recombination of our best chimaeras requires no more IHF than does recombination of wild-type *att*P (data not shown). That the chimaeras continue to require IHF reflects their dependence on the remaining sites, H1 and H′. The lack of an enhanced requirement for IHF, however, argues against the possibility that our chimaeras are active because they contain or create weak IHF binding sites.

Taken together, these experiments confirm our conclusion that the chimaeras create functional *att*P simply because the bend induced by IHF at H2 has been replaced by another source of bending. We believe that the strategy of 'bend swap' experiments is particularly powerful in analysing effects in multiprotein arrays. On the basis of experiments that either altered the protein, the binding site, or the spacing of the array around the binding site, others have suggested[5,18,19] that bending by sequence-specific DNA binding proteins is a critical element for function. In each of these cases, however, it is hard to rule out the possibility that altered function follows from an altered protein–DNA or protein–protein contact rather than from a primary change in the conformation of DNA. By contrast, the

TABLE 2 Integrative recombination *in vivo* and *in vitro*

		Recombination (% of wild type)			
		in vivo		*in vitro*	
attP	Phenotype	(a)	(b)	(c)	(d)
pHN986*	wt	(100)	(100)	(100)	(100)
pHN1006	H2⁻	3	4	10	16
pHN1053	H2⁻	2	5	0.3	<0.1
pHN1043	*att*P-K	2	—	—	<0.1
pHN1045	*att*P-K	175	90	65	79
pHN1050	*att*P-K	12	—	—	16

In vivo recombination between the *att*P plasmids listed and a derivative of phage lambda that carries *att*B was performed as described[9]. The extent of recombination was measured as the per cent of phage progeny that acquired kanamycin resistance. Appropriate controls showed that this capacity depends on the presence of an attachment site in the plasmid and an *int* gene on the phage (not shown). *In vitro* recombination was performed and quantitated as described in Fig. 2.
*, % recombination of pHN986 for the separate experiments shown in columns (a), (b), (c), and (d) was 2.8, 10.9, 57 and 19 respectively.

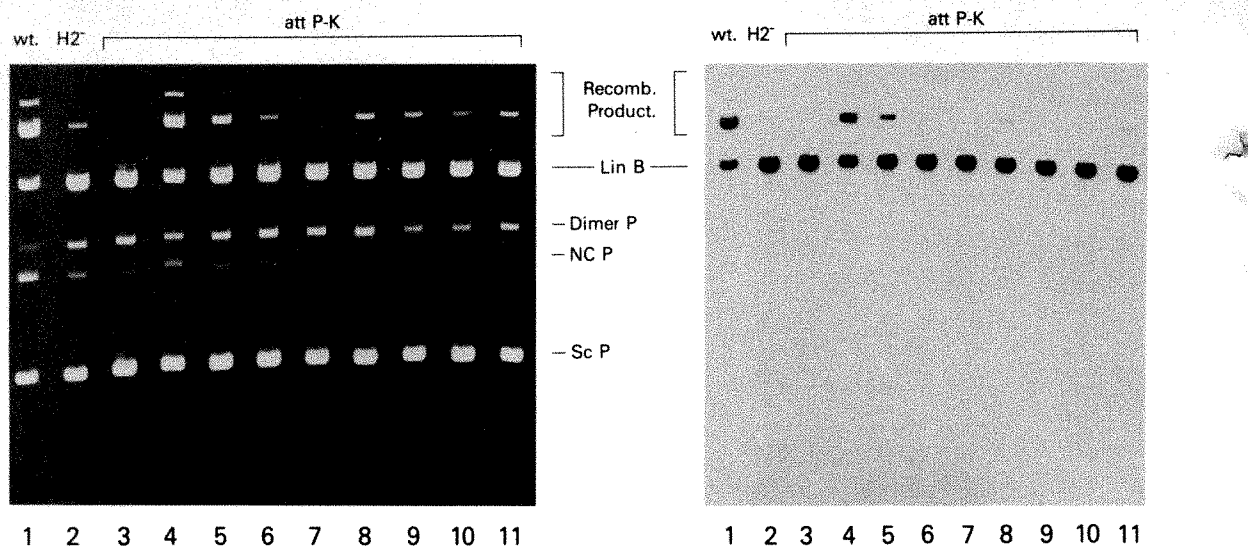

FIG. 2 *In vitro* recombination of *att*P-K chimaeras. The left panel shows the ethidium bromide stained agarose and the right panel shows the autoradiogram of the same gel. *att*Ps used in each reaction are as follows: pHN986 (lane 1), pHN1006 (lane 2), pHN1044 (lane 3), pHN1045 (lane 4), pHN1046 (lane 5), pHN1047 (lane 6), pHN1048 (lane 7), pHN1049 (lane 8), pHN1050 (lane 9), pHN1051 (lane 10), pHN1052 (lane 11). *att*P phenotypes are given above each lane and the position of the substrates and products is indicated in the centre.

METHODS. *In vitro* recombination[22] used 12.5 μg ml^{-1} of each *att*P plasmid primarily as the supercoiled monomer (Sc P) with some nicked circular form (NC P) and dimer (Dimer P) present. All reactions contained an equal amount of the linear form *att*B (Lin B, pBB105 linearized with *Eco*RI, and end labelled with ^{32}P), purified IHF (20–30 nM) and purified Int (70–140 nM) in 50 mM Tris-HCl (pH 7.8), 70 mM KCl, 5 mM spermidine, 0.1 mM EDTA, 50 μg ml^{-1} BSA, 1% glycerol in a final volume of 20 μl. Reactions were carried out at 25 °C for 45 min and analysed on 0.7% agarose gels. Recombination was quantitated using an automated beta detector (AMBIS) to determine the percentage of *att*B substrate converted into product. Construction of *att*P-K clones followed the strategy diagrammed for *att*P-CRP. A 77 bp blunt ended fragment containing 6'A tracts' (5'-AATTC-(CGGGCAAAAAACGGCAAAAAA)$_3$ CGGGGAATT-3'; ref. 16) was inserted at the *Xba*I site of pBend1 to creat pHN1036. Fragments were liberated from pHN1036, cloned into pHN98 and sequenced as above (pHN1041-pHN1046). Additional +4 bp variant of the chimaeras were also generated (pHN1047-pHN1051) as describe in Fig. 1. The insert sizes (bp) for plasmids pHN1041-pHN1051, respectively are 132, 126, 114, 109, 144, 127, 136, 136, 113, 148, and 131. The distanc (bp) between the presumptive bend centre (the centre of the 'A tracts') an the attachment site arm (see Table 1) for pHN1041-pHN1051 are 71, 5 54, 48, 88, 79, 71, 75, 48, 92, and 83. In plasmids pHN1041, pHN104 pHN1045, pHN1047, pHN1048, pHN1049 and pHN1050 the 'A' rich stran of the insert is continuous with the top strand of *attP* whereas in pHN104 pHN1043, pHN1046, and pHN1051 the inserts are in the opposite orienta tion. pHN1052 was created by removing the *Xba*I insert that contains th 'A tracts' from pHN1045 and religating it in the opposite orientatio pHN1053 was constructed by inserting a blunt ended *Taq*I fragment fro phage lambda (coordinates 44,667–44,811) between the *Nde*I and *Sp* sites of pHN986.

replacement strategy, especially the replacement of a protein-induced bend by a sequence-directed bend, seems less beset by alternative interpretations. It remains to be seen whether such replacements would be successful at the remaining IHF sites within *att*P. Even if IHF is needed to form protein–protein interactions at another site, we believe that our data establish the principle that, in building a functional nucleoprotein array, phage λ has evolved to use an accessory protein to change the conformation of DNA. Although we do not know how the bend is actually used, we are attracted to the idea that the bend acts as an architectural element. That is to say, by bringing distant parts of *att*P closer together, this bending could facilitate the interaction of other components of the intasome[10,13,20]. Indeed, Landy and coworkers[19] have recently shown that IHF assists the communication between Int bound to different segments of an attachment site. Although such experiments leave open the possibility that IHF acts by contacting Int bound to the arm so as to improve its affinity for the core region, it has been suggested from these data that the role of IHF is to bend the DNA[19], a proposal entirely consistent with the conclusions of the present work.

In its size and complexity of binding sites, *att*P resembles other important loci of DNA metabolism in both prokaryotes and eukaryotes. At loci such as origins of replication, transcriptional control region and others, the same strategem used by the phage integration system may also apply: accessory proteins that bend DNA may help in the construction of condense nucleoprotein arrays. In testing for such a possibility, the bend replacement approach that we have introduced in this pap should be very useful.

Phasing of protein-induced DNA bends in a recombination complex

MANY of the structures responsible for replication, transcription initiation and recombination arise from complex sets of protein–protein interactions and the folding of DNA in three dimensions, with protein-induced bending of DNA often playing an integral role. The magnitude and orientation of DNA bending induced by various single proteins has been estimated by gel mobility shift methods[1–4] and by modelling of crystallographic data[5]. The site-specific recombination by which bacteriophage lambda (phage λ) integrates into the chromosome of its host *Escherichia coli* requires a host protein, 'integration host factor' (IHF), which is known to be able to bend the DNA to which it binds. To determine the three-dimensional path of DNA within the higher order structure responsible for phage λ site-specific recombination[6,7], we have determined the relative direction of IHF-induced bending at each of the three binding sites within the complex[8,9]. IHF, which appears to bend DNA by more than 140°, is a major determinant of the DNA path in the recombination complex[3] and is also involved in a wide range of other cellular events[10].

Two different methods were used to determine the phase of a pair of IHF-induced bends. One method depends upon alterations in electrophoretic mobility as a function of spacing between the IHF binding sites[1,2]; the other depends on alterations in the stability of IHF-DNA complexes as a function of spacing. Phasing information derived from the cyclical variation of complex stability is independent of electrophoretic mobility and circumvents complications caused by intrinsic curvature. Results from these two methods are in excellent agreement and lead to a model for the recombination complex formed with the phage λ integration site *attP*.

Two sets of 12 DNA fragments derived from *attP* were constructed with each successive fragment containing one additional base pair (bp) between the pairs of IHF binding sites H1 and H2, or H2 and H′ (Fig. 1*a*). Insertion of 1 bp rotates the two DNA-binding sites with respect to each other by an average of 34°(ref. 11) and also changes the position of the two fragment termini with respect to one another in three-dimensional space. Incremental insertions of single base pairs through a full helical turn between two DNA bends produces a cyclic variation in the electrophoretic mobility of fragments in polyacrylamide gels. The minimum and maximum mobilities occur for those fragments that have two bends in phase, or out of phase, respectively[1,2]. With the two bends in phase, a closed compact structure is predicted; when the two bends are out of phase the structure is open and extended (Fig. 1*b*). These models suggested that there might be a difference in the stability of the IHF-DNA complex as a function of the relative orientation of the DNA arms (caused by steric hindrance) as well as variation in electrophoretic mobility.

When IHF is bound to any of the fragments, bands with three different mobilities are observed (Fig. 2*a*, 2*b*). The fastest migrating band corresponds to unbound DNA. As observed previously[12,13], *attP* has intrinsic curvature and the unbound fragments have an altered mobility as a result of changing the phasing between multiple A-tracts. Because this altered mobility is not in phase with the protein-induced bends, it is difficult to rigorously separate these two effects. The two slower migrating

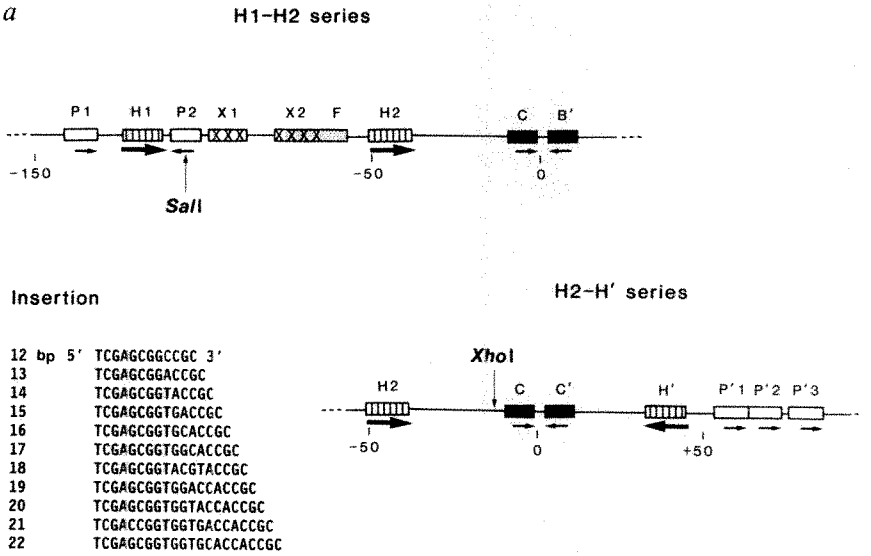

FIG. 1 *a*, The protein-binding region of *att* fragments containing two IHF binding sites. The parent fragment in each series is derived from *attP* and contains the protein binding sites for Int (P1, P2, C, B′, C, C′, P′1, P′2 and P′3), IHF (H1, H2, and H′), Xis (X1, X2) and Fis (F) (see also Fig. 4). Taken together, the parent fragments span the full *attP*. *b*, the path of DNA predicted for fragments containing a 13 bp (left panel) and an 18 bp (right panel) insertion between two occupied IHF binding sites. The figures were generated with the DNA bending program from DNASTAR Inc. (Madison) based on the length of restriction fragments used in this study (419–516 bp), the distance between the IHF binding sites (91 and 96 bp for the 13 bp and 18 bp insertion respectively), and the magnitude of the IHF-induced bends (> 140°) (ref 3).

METHODS. H1–H2 series: oligomers of 12–22 bp were inserted into the *Sal*I site of a pJT33 (ref. 19) derivative in which a 994 bp *Bam*HI–*Sty*I fragment in the pBR327 backbone was deleted. The parent and the set of 11 plasmids were cut with *Eco*RI and *Pfl*MI to generate fragments of 419, 431–441 bp. H2–H′ series: the same oligomers were inserted into an *Xho*I site of a pJT96 (ref. 13) derivative in which the 3,533 bp *Asp*718–*Pst*I fragment was ligated to the 1,129 bp *Pst*I–*Bam*HI fragment of pBR327. The parent and the set of 11 plasmids were cut with *Eco*RV and *Bam*HI to generate fragments of 494, 506–516 bp. All plasmids were sequenced with a kit from U.S. Biochemical Corp. (Cleveland, Ohio).

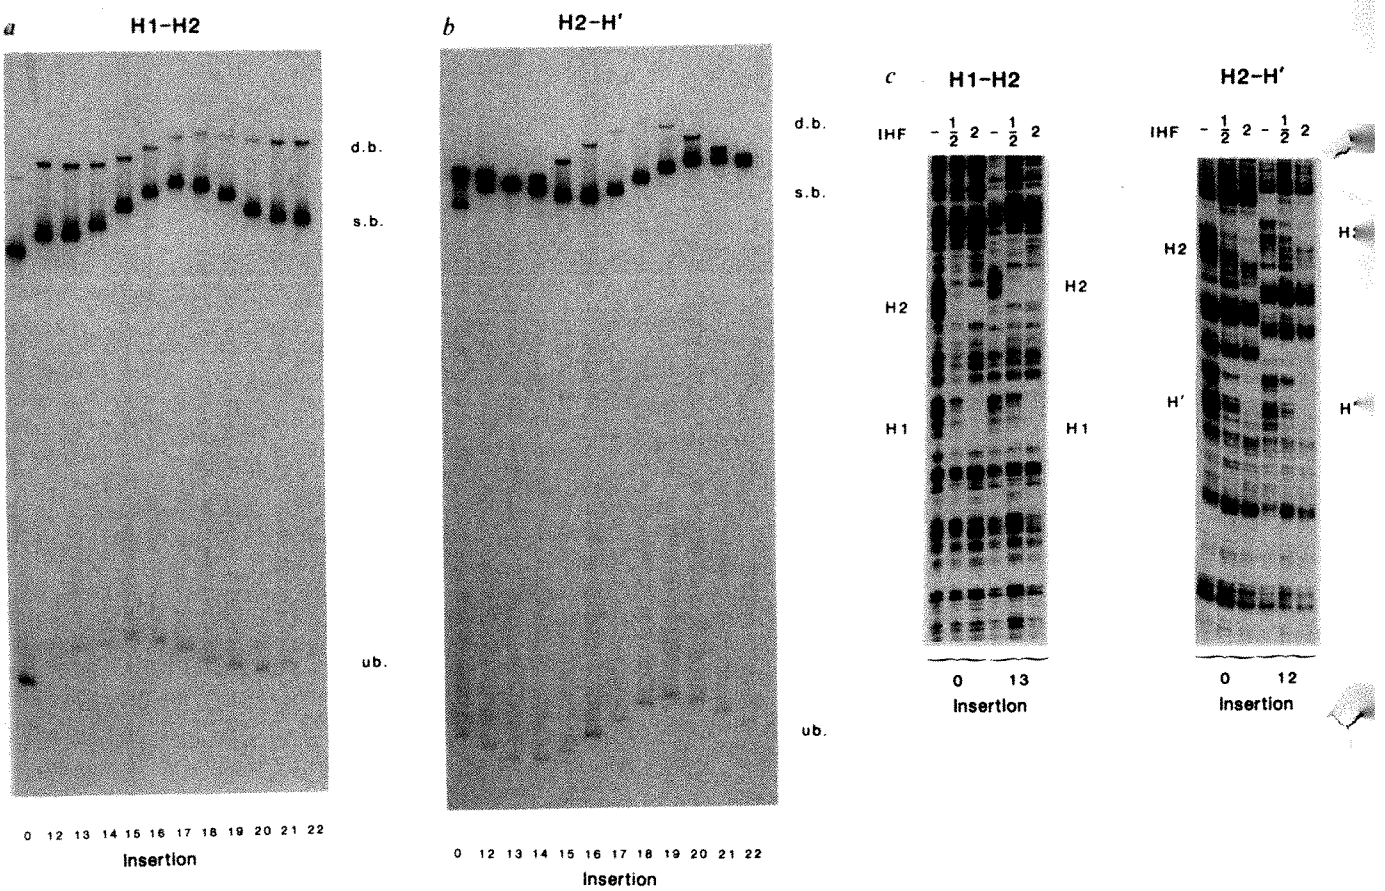

FIG. 2 Polyacrylamide gel electrophoresis of IHF-DNA complexes. *a*, H1-H2 series. *b*, H2-H' series. The three bands correspond to unbound DNA (ub.), DNA with a single IHF bound (s.b.), and DNA with IHF bound to both sites (d.b.). *c*, Nuclease protection assay of IHF-DNA complex. The degree of protection of IHF binding sites was used to determine site occupancy. The DNA isolated from the single-bound species shows partial protection of both binding sites and the DNA from the double-bound species shows complete protection. The partial protection exhibited by the single-bound species is caused by IHF binding to each site for a time proportional to the binding site affinity[30]. The observed relative affinities of the IHF sites, H2 ≥ H' > H1, are in agreement with earlier studies[8].

METHODS. Fragments were purified after end-labelling at the *Eco*RI (H1-H2 series) or the *Bam*HI (H2-H' series) sites using the Klenow fragment of DNA polymerase and [α-^{32}P]dATP. Binding and electrophoresis of IHF-DNA complexes were as described[3]. The results using 1/2 unit of IHF are shown. For the nuclease protection experiment, IHF-DNA complexes were digested with neocarzinostatin and electrophoresed on 5% polyacrylamide gels. DNA associated with the single- and double-bound species (determined by IHF titration) was electroeluted and electrophoresed on 7.5% polyacrylamide 8 M urea gels.

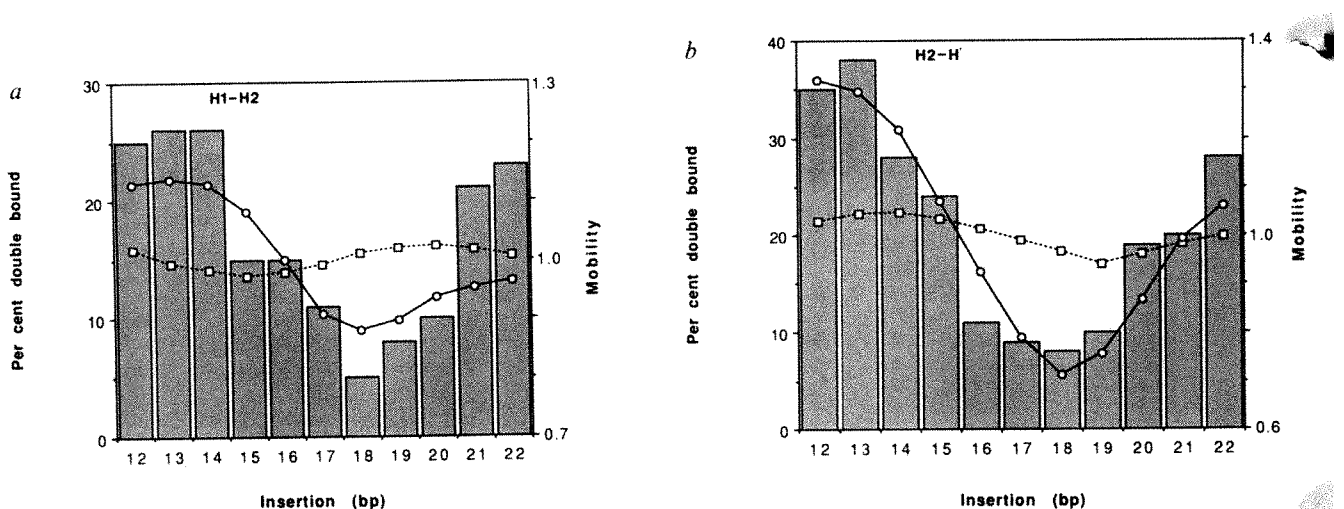

FIG. 3 Stability and relative mobility of the double bound species plotted as a function of insertion length. *a*, H1-H2 series. *b*, H2-H' series. The bar graphs depict the percent of radioactivity transferred from the labelled substrate to the species having IHF bound to both sites, as determined by scanning with a laser densitometer. The proportion of radioactivity associated with the double-bound species varied with the same helical periodicity for all the concentrations of IHF tested (1/4-2 units). The relative mobility is calculated as the fractional variation in electrophoretic mobility normalized to the average for the set of 11 fragments. ○, relative mobility of the doubly bound species; □, relative mobility of the unbound DNA.

bands correspond to DNA with IHF bound to either one or to both sites on the molecule.

To identify the single-bound and the double-bound species, IHF titrations and nuclease protection experiments were performed. The IHF titration indicated that the slowest migrating band for each fragment of the H1-H2 series contained IHF bound to both sites. This was also the case for the H2-H′ series, with the exceptions of the fragments with insertions of 0, 12, or 13 bp, for which the faster migrating band contained IHF bound to both sites. These results were confirmed by nuclease protection experiments with the single- and double-bound complexes (Fig. 2*c*).

The proportion of DNA with IHF bound to both sites varies as a function of the spacing between the two sites (Fig. 3*a*, *b*). On the same graph is a plot of the relative electrophoretic mobility of the double-bound species as a function of spacing. Both parameters exhibit the same helical periodicity, as predicted for a dependence on the relative orientation of the IHF-induced bends.

For the fragments with IHF bound to both sites, the greatest fraction of label is associated with those complexes having the highest relative mobility and hence the most extended structure. As the relative orientation of the bends is changed to produce a more compact structure with the ends of the DNA in the same vicinity, there is a decrease in the stability of the complex as a result of the interfering DNA. To verify this interpretation of the results, we shortened the length of DNA flanking the H1 and H2 binding sites for the fragments with the 13 bp and 18 bp insertions. Removing 97 bp and 54 bp from the left and right ends, respectively, eliminated the difference in binding affinities (data not shown).

The close correspondence between the complex-stability and mobility results corroborates the interpretations of these types of analyses and is consistent with the earlier measurements of IHF-induced bends in phage λ *attP* (ref. 3). Because the lowered stability of the double-bound complexes is probably due to close contacts that are made by the distal arms of the DNA fragment, the effect of phasing may only be observed with appropriately spaced binding sites and proteins that bend the DNA by more than 90°, as does IHF. These stretches of DNA must bend or twist to avoid each other, thus distorting either the DNA or the optimal protein-induced bend, thereby decreasing the stability of the complex. Induced bends of greater than 90° may be common, as IHF, FIS, CAP, Xis and γδ resolvase all fall into this category[3,5,14,15].

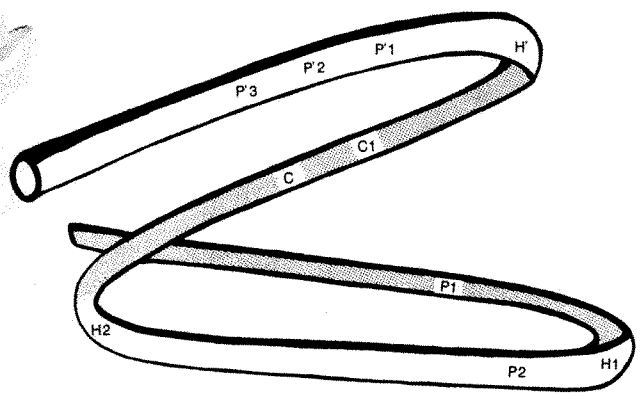

FIG. 4 Model of the three-dimensional path of *attP* DNA. The drawing shows the path of *attP* DNA that would result from IHF binding to the three sites given a relative phase of 103° between adjacent bends and a magnitude of 140° for each bend. There are two types of Int binding sites: arm-type (P1, P2, P'1, P'2, P'3) that are recognized by the N-terminal domain of Int, and core-type sites (C and C'), that are recognized by the C-terminal domain, and are the sites of strand exchange during recombination[29]. Int does not induce significant bends in the DNA[3], but has the capacity to bridge two DNA binding sites through its autonomous binding domains[28].

The complex stability and mobility data indicate that the IHF binding sites in *attP* are not in phase. For both the H1-H2 and the H2-H′ series, the addition of 18 bp places the two binding sites on the same face of the DNA helix. If one takes the value of 10.5 bp per turn for the average helical screw[16-18], 3 more bp (corresponding to 103°) are required to bring the binding sites back to their natural orientation. Thus, the bend at H2 is ~100° out of phase relative to H1. Although the orientation of H2 and H′ are opposite, these two bends are also ~100° out of phase (in the same rotational sense). Because the fragments were derived from *attP*, the effect of the intrinsic curvature of *attP* on the IHF-induced bends is included. Intrinsic curvature may play a role in aligning certain sites more specifically, and may also decrease the binding energy necessary for IHF binding at the H2 and H′ sites, relative to H1, which is in a region where intrinsic curvature is absent[12,13].

There is considerable evidence[3,19-25] that the integration of phage λ into the *E. coli* chromosome requires the formation of a higher-order complex of *attP* and the proteins IHF and Integrase (Int), which carries out the cutting and resealing of *att* site DNA during recombination[26,27]. We have constructed a model of the three-dimensional structure of *attP* using the relationship between the IHF-induced bends described above (Fig. 4). Addition of the three phased bends results in a left-handed coil structure as predicted on the basis of topological analyses[24,25]. (This is topologically equivalent to a right-hand plectonemic wrap.) The degree to which the bends are out of phase implies an extended structure in which the P and P′ arm-type Int binding sites are far apart in three dimensions. This structure does not take into account any conformational changes induced by supercoiling or Int, both of which are likely to condense the extended structure so that distal regions of the complex could communicate.

Although we are not yet able to incorporate all perturbations of the DNA path, these experiments lead to a preliminary model of the higher order structure involved in phage λ integrative recombination that correctly predicts topological features[24,25], and also provides a DNA framework for the known bridging capacity of Int[28,29] and long range interactions within the intasome[19,20,22]. □

ACKNOWLEDGEMENTS. We thank Lucy Rodrigues and Bonnie Tracy for technical assistance, Joan Boyles for preparation of the manuscript and William Montigny and Simone Nunes-Duby for suggestions. This work was supported by grants from the NIH (A.L.) and the ACS (J.T.).

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

Submission. *All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

Analytical ultracentrifugation reborn

H.K. Schachman

Analytical ultracentrifugation is still the best method for quantitative studies of the interactions between macromolecules. There will soon be a modern alternative to the ancient Beckman Model E.

For about a half century, beginning with the pioneering work of Svedberg and his collaborators in Uppsala, Sweden, the ultracentrifuge was arguably the most powerful tool available for the study of macromolecules of biological interest. By the 1930s, those workers (and others who spent a year or two at that Mecca) had already developed the principles and techniques of sedimentation velocity and sedimentation equilibrium[1].

The former led to the first reliable estimates of the shape of macromolecules by combining measurements of the sedimentation coefficient and the molecular weight with hydrodynamic theories for the frictional resistance of particles of different shapes as they migrated through aqueous solutions. Sedimentation equilibrium measurements based on rigourous thermodynamic principles yielded accurate values of the molecular weights of molecules, from sucrose to whole viruses with 'molecular weights' of as much as 5×10^7.

The impetus to biological research resulting from the construction of a high-speed centrifuge capable of generating fields roughly 4×10^5 times that of gravity — coupled with ingenious optical systems that permitted molecules to be viewed directly as they moved through solvent — is virtually inestimable. It is hardly an exaggeration to state that the field of protein chemistry (in terms of molecular weights, subunit composition and association-dissociation equilibria) derives from the design and application of the ultracentrifuge[2]. Perhaps the greatest surprise to the early pioneers was the demonstration that protein molecules were homogeneous and had well-defined molecular weights. This seminal conclusion from ultracentrifugal studies generated unbounded enthusiasm for structural investigations, leading ultimately to the elucidation of the sequence of amino acids in the polypeptide chains of innumerable proteins.

Because the oil turbine ultracentrifuge was extremely complicated and expensive, few laboratories in the world were equipped to construct and maintain them. In only a few years, however, the ingenuity of research workers resulted in the development of the air-driven ultracentrifuge[3], leading rapidly to a doubling or more of the number of ultracentrifuges in routine operation. But this was still insufficient for the demands of research workers interested in the physical chemistry of proteins and nucleic acids. This deficiency was remedied in 1948 by the development of an electrically driven commercial instrument[4] with much greater reliability and ease of operation. Despite the cost of the instrument and the complexity of interpreting the wealth of information which could be deduced from sedimentation velocity and sedimentation equilibrium experiments, more than 2,000 commercial instruments were operating in laboratories throughout the world from 1950 to 1970.

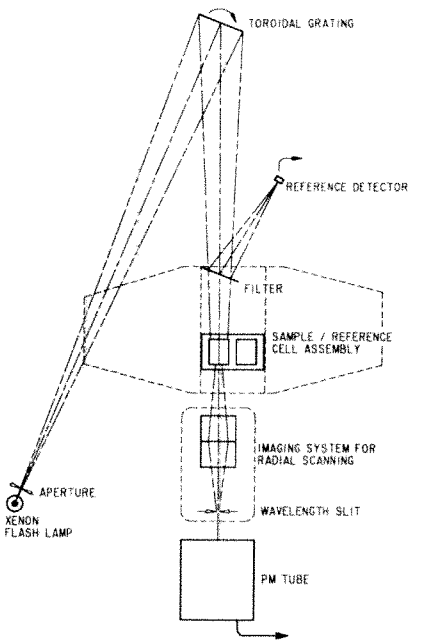

FIG. 1 The scanning absorption optical system of the Beckman Optima XL ultracentrifuge.

But by 1980 — despite the almost frenetic activity devoted to the design of new cells, the incorporation of different optical systems, the development of additional theoretical treatments[5-7], and the application of ultracentrifugation to a diverse host of important biological problems — the use of the instrument came to a rather abrupt end.

What happened? Were better, more reliable and more versatile techniques developed that could be used instead of ultracentrifugal methods? Or were the questions asked by protein chemists and molecular biologists in the 1980s so different that sedimentation techniques had become obsolete?

Not obsolete

To research workers interested in the absolute determination of the molecular weights and shapes of macromolecules, the association-dissociation equilibria of oligomeric proteins, and the measurement of the interactions between dissimilar macromolecules, the ultracentrifuge is still the tool of choice. No other physical chemical tool surpasses the ultracentrifuge for these studies.

But molecular biologists in the early 1980s who were interested in molecular interactions between different proteins, or between proteins and nucleic acids, were content with 'yes or no' answers rather than equilibrium constants and free energy changes. For them, filter binding assays, Sephadex columns and polyacrylamide gels provided the desired information.

Now, however, with literally hundreds of proteins produced by the technique of site-directed mutagenesis awaiting characterization, precise techniques for physical chemical investigations are needed. Indeed, in a *News and Views* commentary two years ago, Gratzer[8] discussed the use of analytical ultracentrifugation in studying the remarkable shape changes which some proteins exhibit in response to environmental perturbations: "The study of these phenomena has led to a return to the quantitative virtues of physical protein chemistry and a resurgence of ancient crafts: The whine of the Model E is once again to be heard in the land, like the voice of the turtle, to gladden the hearts of the old-timers." For the benefit of some readers, Gratzer added a footnote pointing out that the Model E is "not an early car, but the Beckman analytical ultracentrifuge".

Reinvention of a classic

Most 'old-timers' (though having fond memories of the Model E and in some cases still using it) are now excited about the recently announced plan by Beckman to make available a new analytical ultracentrifuge based on their Optima XL series.

Gone will be the noisy, old centrifuge drives with their relatively limited lifetimes and the requirement for a family of gears which permitted the rotor to spin at 70,000 r.p.m. even though the drive operated at a much lower speed. With their new, air-cooled induction motor, warranted for ten years, we look forward to smooth, constant-speed operation without the rotor precession that plagued workers in the past. Also, the ultracentrifuge will be much smaller than the Model E — a blessing to the research worker who almost invariably has too little available laboratory space. Gone also will be the

'medieval' temperature control system, with a needle at the base of the rotor dipping into a cup containing mercury to complete an electrical circuit. We all look forward to the disappearance of this archaic method of measuring and controlling the temperature of the rotor!

At the national meeting of the Biophysical Society this year, Beckman unveiled its new photoelectric scanning absorption optical system (Fig. 1), which will be completely contained within the vacuum chamber. It will have a range of wavelengths, sensitivity, linearity and accuracy that should permit routine studies at protein concentrations far lower than most workers would have dreamt possible. Moreover, the optical system should have sufficient resolution that, coupled to automatic data systems, the workers will obtain both integral curves (representing concentration versus distance) and derivative curves in the form of plots of gradient versus distance. Thus, those workers who are so accustomed to the 'peaks' produced directly by the schlieren optical system will have their equivalent with the added advantages of the discrimination and senstivity of absorption optics. A mere change in the wavelength of the incident light over a broad range will provide information about the chemical composition of the sedimenting material. (In contrast, refractometric methods are incapable of providing such information.) Beckman plans also to incorporate a Rayleigh interference optical system so that the remarkable precision inherent in interferometry will be available to those workers interested in the highest accuracy of molecular weight determinations by the sedimentation equilibrium technique.

Coupled with all of these dramatic improvements will be new cells, rotors and — most important — automatic operation controlled by convenient, versatile computer programs which will also perform the many, diverse computations needed to determine molecular weights, sedimentation coefficients, homogeneity or heterogeneity of the macromolecules, and to analyse, in quantitative terms, association-dissociation equilibria. We can hardly wait. □

The best of British!

Visitors to British Lab Week, in London, can expect to see a wide range of laboratory products: from gel documentation systems to water purifiers that keep water particle-free.

According to Ultra-Violet Products Ltd, the new video system for **electrophoresis gel documentation** can produce economical high-quality images in less than 10 seconds (*Reader Service No. 101*). Designed specifically for photography of low-light fluorescent patterns such as

Electrophoresis gel documentation from UV Products.

ethidium bromide-stained DNA gels or TLC plates, the system costing under £7,000 (UK) comprises CCD-camera, stand, UV transilluminator with filters, optics and control unit, nine-inch video monitor and video printer. The gel is placed on the transilluminator and the desired image is selected by moving the camera up and down on its stand. The integrated image is stored in a frame buffer and displayed on the video monitor, at which time the user can focus the image, use contrast amplification, edge enhancement or baseline subtraction. At the touch of a button, a 10 × 7.5-cm hard copy of the stored image can be printed on thermal paper, either as a positive or negative. Alternatively, the stored image can be transmitted to a PC for further processsing. UVP will be on stand A248.

New from Jones Chromatography Ltd, is the aptly named Janitor — an ancillary module for HPLC machines designed to **flush out corrosive buffers and solvents** (*Reader Service No. 102*). The £550 (UK) Janitor module is connected to the HPLC pump inlet and allows the pump to deliver up to two solvents other than the mobile phase for preselected intervals. The system operates by using timed switching valves and relays which are activated at the end of a series of chromatographic runs. After completion of the flush cycle, the Janitor relay powers down the system. According to the company, the Janitor will prolong the life of the HPLC column and detector lamp, and will reduce wear and corrosion on the HPLC system. Jones Chromatography can be seen on stand A400.

ABB Metrawatt Ltd's SE571 **storage oscilloscope** will be on show on stand G632 (*Reader Service No. 103*). The SE571 has eight built-in logic channels and can acquire both analogue and digital signals simultaneously. A video contoller and rapid measured data conditioning facility allow a real-time screen display of waveform signals. The company says, data can be printed in less than 10 seconds as either a time diagram or data lists on the system's integrated printer. The instrument also features an auto-ranging facility for the control of amplification and time-base settings for both measuring channels. A computer can be connected to the SE571 via an IEEE 488 interface to control the measuring sequence. The SE571 can store

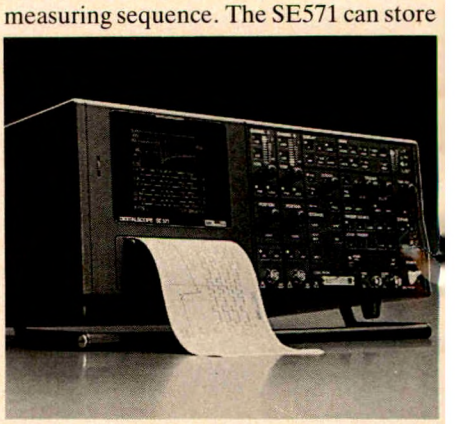

ABB Metrawatt's oscilloscope has 8 channels.

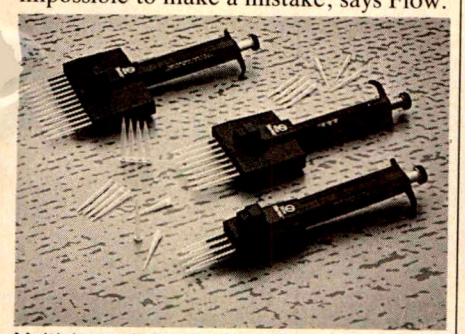
up to ten sets of instrument settings, including measurement range, time-base settings, trigger levels and test signals.

A portable CO2001 **dryer that removes CO_2 and H_2O** from the compressed air for use in critical applications such as FT-IR and NMR spectrometers can be seen on Complete Protection Ltd's stand, number K1004 (*Reader Service No. 104*). The £895 (UK) CO2001 dryer can achieve CO_2 removal to less than 1 p.p.m. and a pressure dew point of less than −70 °C, says the company. The 843 × 305 × 106-mm unit offers particle removal to 0.2 microns and



The CO2001 removes CO_2 and H_2O from compressed air.

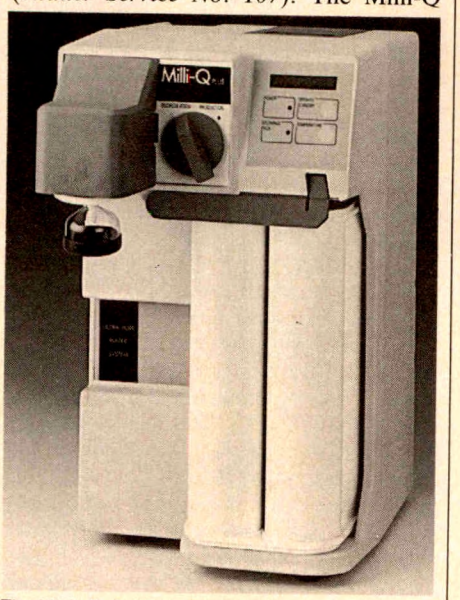
a maximum output rate of 18 litres per minute, says Complete Protection.

Liquid dispensing

For accurate liquid dispensing, Flow Laboratories recommends its new line of lightweight **multi-channel pipettes** (*Reader Service No. 105*). The user simply dials in the required dispensing volume using a colour-coded thumb button. A digital display of the volume appears in an integral window, making it virtually impossible to make a mistake, says Flow.

Multichannel pipettes from Flow.

The pipettes come in three sizes for 4-, 8-, and 12-channel dispensing at a cost of £198 (UK), £247 (UK), and £308 (UK), respectively. Two colour-coded volume ranges are available: yellow for dispensing 5-50 µl in 0.5-µl increments and green for the 50-300 µl range in 5-µl increments. Pipette tips are supplied either sterile or nonsterile and can either be sold separately or in bands of four for rapid replacement during use. Flow can be found on stand C800.



Jencons Scientific Ltd, exhibiting on stand E178, has a **programmable liquid dispensing machine** — the Perimatic — which is suitable for aqueous solutions, sterile and shear-sensitive fluids (*Reader Service No. 106*). The machine uses a peristaltic pump to dispense volumes from 0.5 ml to 1,000 ml, and can dispense automatically at preselected intervals, or be operated manually or via a footswitch control. The Perimatic continuously recycles fluid even when it is not dispensing, which is useful for suspensions, says Jencons. Frothing and splashing can be prevented by programming the dispensing to begin and end slowly. Liquid is contained within the tubing at all times and a different dispensing head is used each time the solution is changed, eliminating the possibility of contamination, says Jencons.

The Perimatic liquid dispenser from Jencons.

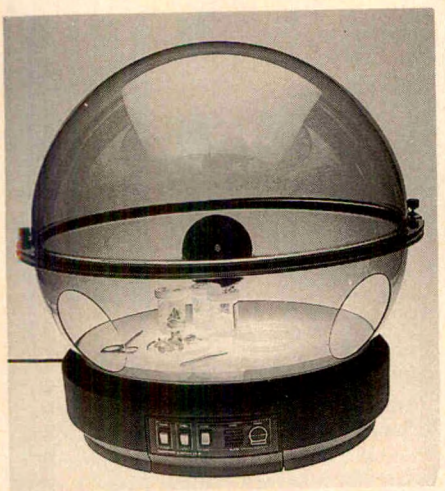
Pure and simple

Millipore Ltd will be featuring a new **water purification system** — the Milli-Q Plus — for general laboratory use or specialist applications such as HPLC, ion chromatography, TOC analysis, and atomic absorption spectrophotometry (*Reader Service No. 107*). The Milli-Q Plus can provide 1.5 litres per minute of ultrapure water that is particle-free to 0.22 µm, has a 18 MΩ-cm resistivity, and less than 10 p.p.b. TOC if pretreated with reverse osmosis, says Millipore. The system uses Millipore's patented purification packs, which the company says are easy to remove and install. An alphanumeric display indicates the operational status of the system, and an alarm alerts the user of the need to change the purification packs. During periods of reduced demand, the system switches to a standby operation of intermittent recirculation. Prices for the Milli-Q Plus, which can be seen on stand E186, start at around £1,900 (UK).

The Milli-Q yields 1.5 litres of water per minute

If your research requires an apyrogenic water source, then Elga Ltd recommends its Elgastat UHP-UF **water purifier** (*Reader Service No. 108*). The unit uses a combination of organic adsorption, ion exchange, ultra-microfiltration, photo-oxidation and ultrafiltration technologies to provide ultra-pure water at flow rates of up to two litres per minute, says Elga. The £2,450 (UK) UHP-UF incorporates a 20,000 molecular weight cut-off ultrafilter to produce water that is particle-, pyrogen- and bacteria-free. Special features include a programmable rinse system that prevents organic contaminant build-up, and continuous recirculation which inhibits microbial growth and attachment. Each unit is fitted with a water-quality meter and an alarm which indicates when purity falls below the desired level. The UHP-UF can be fed from raw mains, Elgastat Prima (reverse osmosis) or deionised water. Elga will be on stand E198.

Elga's water purifier screens out pyrogens.



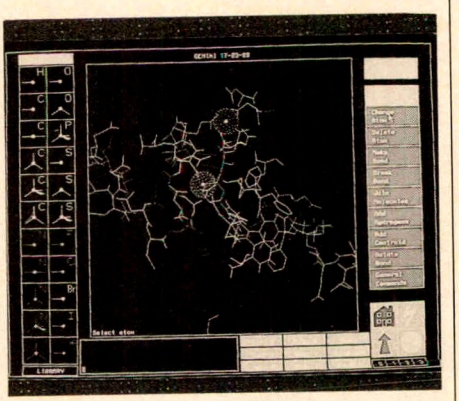
The right environment

Autogene is the new compact **programmable waterbath** from Grant Instruments Ltd, who are exhibiting on stand H0150 (*Reader Service No. 109*). Designed for efficient thermal transfer and rapid automated temperature cycling from 0 to 99 °C, the waterbath offers considerable

advantages over metal thermostats, says the company. Autogene comes with removable test tube racks for a range of test tube sizes and a microtitre plate holder. The instrument can store up to nine run programs: an additional program is available for testing experimental protocols. Each program can include pre- and post-treatment parameters and can have up to 99 cycle repeats. Cycles can contain up to three setpoint/hold segments and the instrument provides a rapid rate of temperature change between set-points, says Grant.

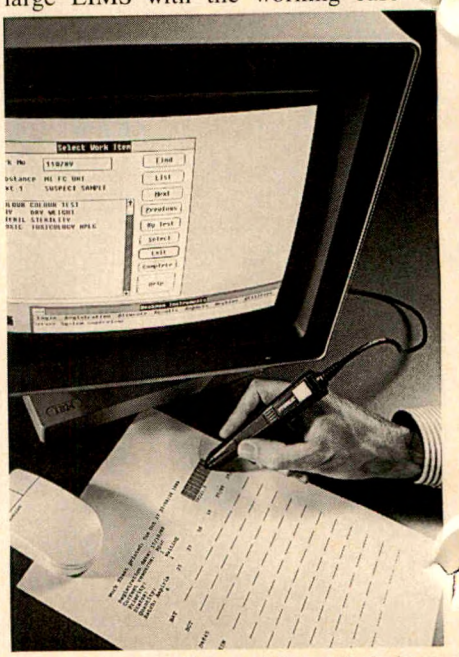
To overcome the problems associated with using water or oil for heat transfer, Jaytee Biosciences Ltd have come up with the BioOven — a **programmable oven** which uses forced air as a heating and cooling system (*Reader Service No. 110*). The £2,250 (UK) BioOven has a 500-cubic inch capacity and can hold 200 microcentrifuge tubes or four 96-well microtitre plates. Various heating and cooling modes are available, including isothermal operation and temperature cycling from ambient to 150 °C. Temperature sensors ensure a temperature variance of less than 1 °C, says Jaytee. The BioOven can store up to eight programs, each containing a maximum of six ramp/soak segments per program. The company says that the BioOven offers fast ramp rates of up to 1 °C per second. For added flexibility, programs can be linked together and can be set to operate 1-9999 cycle repeats. The BioOven can be seen on stand D822.

Visitors to stand A432, will be able to see Cleansphere — Safetech Ltd's futuristic-looking benchtop **sterile chamber** which has applications in fields as diverse as biotechnology, horticulture, microelectronics and pharmaceutical research (*Reader Service No. 111*). Cleansphere — developed in conjunction with University College, Cork — incorporates a Hepa filter cartridge and provides air-class 100 sterility, says Safetech. A built-in alarm indicates the sterility level and the need for filter replacement. The £830 (UK) unit provides all-round vision, a worksurface that is 400 mm in diameter, and easy hands-on access inside the chamber through hand bays. The unit can easily be dismantled for cleaning or access by removing the top-half of the chamber. A light source is fitted as standard and the unit can be treated against static.



Safetech's Cleansphere sterile chamber.

IncuLAB is the portable **laboratory-based incubator** that Robin Instruments Ltd says is ideal for microbial analysis of faecal and total coliform (*Reader Service No. 112*). The instrument can be battery- or mains-operated and features a double incubator, each side of which can be set to run at a different temperature from 30 °C to 50 °C. The temperature variability of the incubator is ± 0.25 °C, says the company. IncuLAB can hold 50 aluminium petri dishes (25 per chamber), which can be autoclaved after use. The complete package includes the incubator and carrying case, two petri dish racks, filter unit with sample cup, lowering cable and vacuum pump, 50 petri dishes and a set of tweezers.



Clever computing

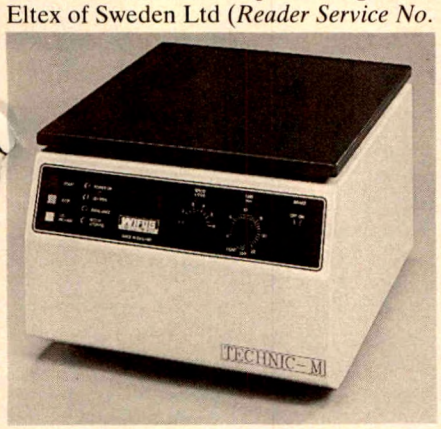
GEMINI is the **3-D real-time molecular modelling** and drug design software package that Hampden Data Services Ltd will be exhibiting, on stand B484 (*Reader Service No. 113*). Developed by the Institute of Cancer Research, UK, GEMINI provides a useful research tool for molecular design and analysis. Designed to run on Silicon Graphics' Personal Iris graphics work stations, the software offers a range of display modes, including solid and dotted surface, wireframe and electrostatic field representations. GEMINI's 'docking' facility allows the user to visualize the 'fit' of molecules. The 3-D images can be colour-coded, rotated and zoomed for detailed analysis, stored, incorporated into further structures, or used as 'building blocks' for more complex molecules. Other features include a cut-and-paste facility for on-screen editing, fragment library, and full compatibility with chemical databases or quantum chemical and mechanics programs.

GEMINI molecular modelling software.

Beckman Instruments Ltd have teamed up the data management capability of large LIMS with the working ease of Microsoft windows to produce EasyLIMS — a **PC-based LIMS software package** designed to suit growing laboratory needs (*Reader Service No. 114*). Developed in collaboration with Harley Systems, the QuickStart turnkey version comes complete with IBM hardware, preloaded Microsoft and Beckman software, user manuals and mouse. Use of Microsoft windows brings data management and report generation within the reach of even inexperienced users, says Beckman. EasyLIMS has an integrated word processor and calculation facility, and post-analysis capabilities include integrated SQL database, spreadsheet, statisyical analysis, and 3-D graphics. EasyLIMS can be used in a stand-alone system or networked with up to ten users. Beckman will be will be on stands G170/C524.

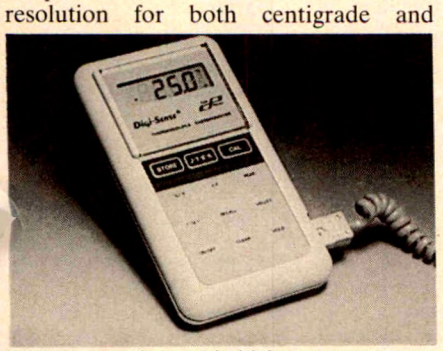
Beckman's EasyLIMS uses Microsoft windows.

Showing for the first time on stand E210 will be VG Data Systems' new **chromatography handling product Xchrom** (*Reader Service No. 115*). The software is based on the X-window standard and offers the



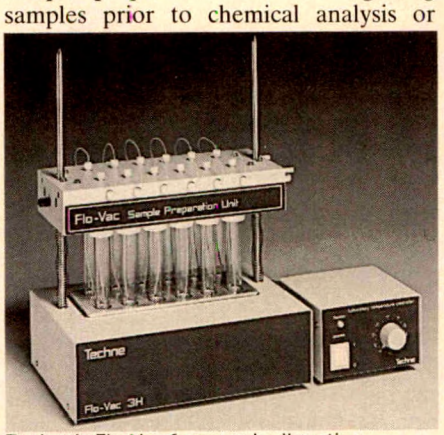
The XChrom system from VG Data Systems.

improved reporting facilities associated with a window-based product, says the company. The software is available on two computer platforms: VAX with the VMS operating system and HP 9000 series with the HP/UX operating system. One of the advantages of X-chrom, says VG Data Systems, is the ability to export chromatograms into DECwrite for integration into reports prepared by word processing. The VG chromatography server is still employed as the acquisition device, which the company says provides the facilities for upgrading and expansion for existing Multichrom and Minichrom users, with the added advantage of a database.



Lab paraphernalia

On view for the first time, on stand number H160, will be the Wifug Technic M — the latest **bench-top centrifuge** from Eltex of Sweden Ltd (*Reader Service No. 116*). This compact centrifuge can be fitted with both angle and swing-out rotors for 15-, 50-, and 100-ml tubes. The Technic M features a stepless speed control, timer and break, and is capable of a top speed of 7,000 r.p.m. (5,055 g) when loaded with four 100-ml tubes, says the company. Safety aspects of the Technic M include a failsafe lock, imbalance cutout and stationary rotor indicator. The basic centrifuge without rotors is £900 (UK).



A bench-top centrifuge from Eltex.

The CP Instrument Co. says its new **hand-held thermometer** has many applications in fields as diverse as food research to industrial production (*Reader Service No. 117*). The thermometer can record temperatures with either a 0.1 °C or 1.0 °C resolution for both centigrade and Fahrenheit. The device can store peak and trough temperatures and can perform differential temperature readings with one probe, eliminating possible probe error says the company. Other features include the facility to accept J, K, T and E thermocouples, 'hold' the display reading on all functions, be field-calibrated against known temperatures, and storage up to eight readings. At £149.50 (UK), the thermometer comes complete with plastic casing and a sealed membrane keypad. CP Instruments will be exhibiting a range of handy laboratory accessories on stand L1290.

CP Instrument's hand-held thermometer.

Techne Ltd will be introducing Flo-Vac at British Lab Week — the multi-purpose **sample preparation unit** for digesting samples prior to chemical analysis or synthesis (*Reader Service No. 118*). Flo-Vac comes in two models: Flo-Vac 3 with an operating temperature range of 25 °C to 105 °C and Flo-Vac 3H with a range of 90 °C to 180 °C. Using the bench-top sample preparation unit, it is possible to perform several tasks *in situ* without interrupting the process. Flo-Vac can provide a controlled oxygen-free atmosphere, which Techne says is useful for oxygen-free digestions of amino acids. Reagents can be added and samples taken at any time. The unit is fitted with nitrogen gas inlet tubes and so gassing can also be performed *in situ*: a vacuum attachment can be used to speed up the evaporation process. The 210 × 330 × 400-mm unit can accommodate up to twelve 16-, 19- or 28-mm tubes. Techne will be on stand K1208.

Techne's Flo-Vac for sample digestion.

For measuring

Dynatech Laboratories Ltd has a Microlite ML 1000 **scanning luminescence system** designed to automate sample screening for 'flash' or 'enhanced' bioluminescence or chemiluminescence reactions (*Reader Service No. 119*). On-board dedicated software offers selectable plate scans, the addition of up to three reagents, and various modes of data presentation. When the system is used with Microlite Removawell Strips, Dynatech says a sensitivity in the femtomole range can be achieved without signal 'cross-talk'. The system can be programmed to elevate and maintain the microstrip temperature above ambient. Data processing functions include graphic analysis and mean, standard deviation and coefficient of variation calculations. The $12,000-$14,300 (US) model 3 system can be supplied with automatic reagent dispensers and a dot-matrix printer.

The PU8710 is the latest **UV-visible spectrophotometer** in the PU8700 Series from Philips Scientific (*Reader Service No. 120*). The PU8710 costs less than £6,000 (UK) and is based on the optical specifications of the PU8700. It has a 2-nm bandwidth and will scan over a range of 190-900 nm. The instrument has been combined with an IBM PC or compatible and Philips' FALCON colour graphics software. This configuration allows the user, via "pop- up" menus, help menus and prompts, to perform data processing functions irrespective of ability. The graphics and data manipulation functions

LIPOSOMES

NEW

REPRODUCIBLE — HOMOGENEOUS — EXTREMELY RAPID

Our new LIPOSOMAT guarantees rapid (5ml within 60 minutes) preparation of uniformly sized unilamellar liposomes. Liposome size is selectable between 25 and ca. 600 nm diameter. Sample volume is normally 5-10ml or up to 200ml if used in combination with an additional instrument. Lipid concentration can be up to 300 mg/ml.

Philip's newest UV-visible spectrophotometer.

include dual/triple display, zoom, spectral subtraction, multi-wavelength calculations, and quadratic and linear calibration curves. An optional plotter can provide hard copy in up to six colours. Philips Scientific will be exhibiting on stands D830 and E176.

Full system automation and scale-up facilities are features of the NovaPrep 5000 **semi-preparative HPLC system** from Technicol Ltd, which can be seen on stand K1210 (*Reader Service No. 121*). The system has a 10 to 50-mm column capability and can operate at pressures of up to 5,000 p.s.i., says Technicol. The interactive TurboPrep software package, designed to run on a 286/AT computer, allows full methods development capability and provides controlled gradient formation, sample injection and fraction collection. A special feature of the NovaPrep 5000 is the ContinuRinse pump design, which the company says can prolong the life of the pump's piston seals.

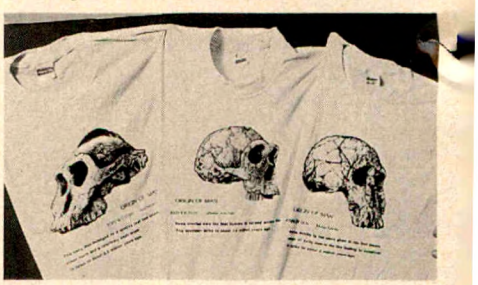
The QuikChem AE **automated ion analyser** features the combined power of flow injection analysis and ion chromatography in one instrument, and can be seen on the Roth Scientific Co. Ltd stand, number H140 (*reader service no. 122*). The system is capable of performing multichannel analysis with up to seven channels operating in parallel. IC can be performed either sequentially or simultaneously with FIA-based methods, with method switching taking less than 15 minutes, says Roth. The company says, QuikChem AE offers a sample throughput of 90-120 samples per hour, fast start-up and short analysis times, with sample processing taking less than one minute for FIA. An integral part of the system is an IBM PC-XT compatible computer and QC/QA software, which provides automated system set-up, sampling, dilution. The system provides real-time data processing, including corrections for baseline drift, dilution and weight factor calculations, and interchannel relationship determination.

Biotech Instruments Ltd, exhibiting on stand L1254, are the UK distributors for Bioanalytical Systems' BAS 200A **chromatographic analyser** for PTH-amino acids, peptide mapping and free amino acids (*Reader Service No. 123*). The system uses a narrow-bore (0.21 cm) column for PTH-amino acid analysis, and has com-

Biotech Instruments distributes the BAS 200A

puter-controlled start-up and operation. The company says, all 20 PTH derivatives can be resolved in less than 18 minutes, with cycle times of 30 minutes and a sensitivity of less than 200 femtomoles per compound. The BAS 200A can also be used for peptide mapping by virtue of the tandem variable wavelength UV and dual-channel amperometric detectors in the BAS 200A. The amperometric detector can also be used for the determination of free, primary amino acids using the OPA-tert butylthiol derivitization method developed by BAS, which the company says has a sensitivity of 50 femtomoles for gamma-aminobutyric acid.

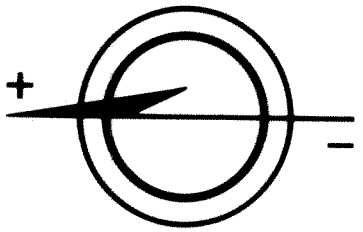
Spectra FOCUS is the new real-time **scanning UV/Visible detector** for liquid chromatography that Spectra-Physics will be exhibiting, on stand E514 (*Reader Service No. 124*). The detector can be used for single- or multiple-wavelength operations. Easy-to-change flow cells for analytical, micro, biotech, and preparative LC or capillary electrophoresis, gives



The QuikChem AB automated ion analyser from Roth Scientific.

The Spectra FOCUS scanning UV-visible detector.

the machine added flexibility, says the company. Dedicated chromatography software for use on an IBM PS/2 computer offers complete instrument control.



Budding anthropologists may be interested in the novel line of T-shirts, sweat shirts and ties depicting skulls of *Australopithecus boisei*, *Homo habilis* and *Homo erectus* (*Reader Service No. 125*). These fashion items were designed by Richard Leakey, palaeontologist and Director of the National Museum of Kenya, Nairobi, who licensed Schreter Neckwear of Baltimore to manufacture the products. The company's President, Harvey Schreter, has had a lifelong interest in anthropology and primitive art and hopes that the designs will be enjoyed by "genuine as well as arm-chair adventurers" alike. Harvey and Phillis Schreter witnessed Leakey's latest find first hand when, in 1988, they joined him on a dig in Lake Turkana, Northern Kenya, at the site where the Leakey team discovered the oldest complete prehistoric skeleton ever found — that of a 1,6000,000 year-old *Homo erectus* boy. A proportion of the profits from the sale of these items

T-Shirts featuring ancient skulls.

will go towards funding the National Museum of Kenya and the ongoing research efforts of Leakey in East Africa. T-shirts sell for £12 (US), sweatshirts for $25 (US), silk-blend ties for $16.50 (US) and all-silk ties for $25 (US).

These notes are compiled by Diane Gershon from information provided by the manufacturers. To obtain further details about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

APPLIED AND THEORETICAL ELECTROPHORESIS

The Official Journal of the International Electrophoresis Society

Editor in Chief Carl R. Merril, *Bethesda, MD, USA*

CONTENTS OF THE FIRST TWO ISSUES INCLUDE:

Editorial
Carl R. Merril

Differential phosphate labeling of stress protein polypeptides in toxic dose response during S-phase of mouse lymphoma cells: a micro-electrophoretic study
J.L. Pipkin, J.F Anson, W.G. Hinson, E.R. Burns & D.A. Casciano

Differential [^{32}P]-labeling of chemically induced stress proteins in S-phase mouse lymphoma cells
James L. Pipkin, Jeanne F Anson, William G. Hinson, E. Robert Burns & Daniel A. Casciano

A new mode of rotating gel electrophoresis for fractionating linear and circular duplex DNA: the effects of electrophoresis during the gel's rotation
Philip Serwer & Shirley J. Hayes

Synthesis of buffers for generating immobilized pH gradients. I: Acidic acrylamido buffers
Marcella Chiari, Elena Casale, Enzo Santaniello & Pier Giorgio Righetti

Synthesis of buffers for generating immobilized pH gradients. II: Basic acrylamido buffers
Marcella Chiari, Elena Casale, Enzo Santaniello & Pier Giorgio Righetti

Rehydratable agarose gels: Use of low EEO agarose without charged additives
Erich Gombocz & Andreas Chrambach

Oxidation of alkaline immobiline buffers for isoelectric focusing in immobilized pH gradients
Pier Giorgio Righetti, Marcella Chiari, Elena Casale & Claudia Chiesa

Isoelectric focusing of recombinant interferon-ß
Susan Hershenson & Jody Thomson

Computerized classification of two-dimensional gel electrophoretograms by correspondence analysis and ascendant hierarchical clustering
Thierry Pun, Denis F Hochstrasser, Ron D. Appel, Matthieu Funk, Valérie Villars-Augsburger & Christian Pellegrini

An equation for DNA electrophoretic mobility in agarose gels
Charles E. Willis, Diana G. Willis & Gerald P. Holmquist

The mechanism of DNA's fractionation during pulsed-field agarose gel electrophoresis: a hypothesis
Philip Serwer

Improved separation of multi-locus hypervariable DNA restriction fragments by field inversion gel electrophoresis and fragment detection using a biotinylated probe
Craig Fowler, Jenny D. Skinner, Leigh A. Burgoyne & James L. McInnes

The effects of field inversion electrophoresis on small DNA fragment mobility and its relevance to DNA polymorphism research
Pablo V. Gejman, Natraj Sitaram, Wang-Ting Hsieh, Joel Gelernter & Elliot S. Gershon

'Catalysts' for polyacrylamide gel polymerization and detection of proteins by silver staining
Denis F Hochstrasser & Carl R. Merril

Rapid scanning thermal lens laser transmission densitometer
Konan Peck, Tshenge Demana & Michael D. Morris

Mixture decomposition applied to the analysis of two-dimensional electrophoretic separation of protein samples
John Taylor & Carol S. Giometti

Thermally reversible gels in electrophoresis. I: matrix characterization
Pier Giorgio Righetti & Robert S. Snyder

Submicrogram quantities of unstained proteins are visualized on polyvinylidene difluoride membranes by transillumination
Juan A. Reig & David C. Klein

Fingerprinting of proteins cleaned in solution by cyanogen bromide
Rose N. Skopp & Leslie C. Lane

A zone electrophoretic-isoelectric focusing study on the inactivation of human Alpha 1-Antitrypsin by elastase

University of Tromsø

PROFESSOR OF BIOCHEMISTRY

AT THE WORLD'S NORTHERNMOST UNIVERSITY.

The position of profesor of biochemistry is open at the Institute of Medical Biology (IBM), the University of Tromsø. IMB has research groups in Biochemistry, Cell biology, Medical physiology, Arctic biology, Pharmacology, Experimental pathlobgy and anatomy, Normal and Pathological Anatomy, Immunology, Microbiology, Virology, Biotechnology and Clinical chemistry.
There are good opportunities for cooperation between research groups as well as with the University Hospital.
The institute has modern labroratory equipment. There are joint service functions for the Institute, including: glass wash, media preparation, cell culture, electronic, mecanic and carpenter, workshop etc., animal facilities, central storeroom, audio-visual department and electron microscopy.
It is desirable to increase the competence in the areas ogprotein chemistry, protein engineering and enzymology. National research councils will give considerable support to the advancement of these areas of research in Tromsø. Research and teaching background relevant to our current programmes will be taken into consideraion in our evaluation of the applicants. Emphasis will algo be given to the ability to collaborate and motivate others for scientific activity. If the following scenario appeals to you Tromsø could be the best chioce you ever made: clean air and water, unspoiled nature, splendid scenery, exiting wild life and exellent possibilities for outdoor life summer and winter. Tromsø, with its population of 47000, offers you a good selection of restaurants as well as musical and theatrical events. The University of Tromsø has 3500 students and a scientific staff of 300. (W6495)A

The gross salary is at present NOK 276.792 per year. Applictions including a complete c.v. and list of publications, should be sent in 5 copies together with the relevant certificates to:
The University of Tromsø, P.o.Box 635, N-9001 TROMSØ, NORWAY
Closing date for applications: 15. November 1989
Full directives for application and further information about the professorship can be obtained at the University at the abovementioned address, or from Dr. Bjarne Østerud, Institute of Medical Biology, University of Tromsø, P.O.Box 977, N-9001 Tromsø, NORWAY. Tel.47 83-44733

UNIVERSITY OF MARYLAND at College Park. The Department of Chemistry and Biochemistry invites applications for two tenure-track faculty positions in the general area of Biochemistry at the level of Assistant Professor. Exceptional candidates at the senior level will also be considered. One position is to be a joint appointment with the University of Maryland Center for Agricultural Biotechnology. Outstanding candidates in all areas of biochemistry will be considered. Applicants for the joint Agricultural Biotechnology position with research interests in plant and insect biochemistry and molecular biology are encouraged to apply. Applicants should submit a curriculum vitae, reprints, a concise statement of research plans and objectives and arrange for three letters of reference to be sent by Nov. 1, 1989 to **Professor Richard N. Armstrong, Chairman, Biochemistry Search Committee, Department of Chemistry and Biochemistry, University of Maryland, College Park, Maryland, 20742.** (NW4218)A

Assistant/Associate Professor
Institute of Molecular Biology and Biochemistry
SIMON FRASER UNIVERSITY

Applications are being accepted for a

DEVELOPMENTAL GENETICIST

Candidates should be applying genetic and/or modern molecular approaches to model developmental systems.

Postdoctoral experience and demonstrated research potential are required. Appointment and teaching duties will be in the Department of Biosciences. The Institute was recently established to stimulate expanded graduate training and research and will be occupying a new building in 1992. Set-up funding is available. Applicants should forward a complete curriculum vitae, reprints of most significant recent publications, and three letters of reference to:

Dr. Bruce Brandhorst, Director.
Institute of Molecular Biology and Biochemistry (I.M.B.B.)
Simon Fraser University
Burnaby, B.C. V5A 1S6
Canada

Applications will be evaluated beginning December 1, 1989. Simon Fraser University offers equal employment opportunities to qualified applicants. While all are encouraged to apply, Canadian law requires that consideration in the first instance be given to applicants eligible for employment in Canada at the time of application. (NW4248)A

UNIVERSITY OF EXETER (U.K.)
UNIVERSITAET MARBURG (F.R.G.)
INSTITUT JACQUES MONOD (PARIS)

Biochemists/Molecular Biologists/Immunologists

Applications are sought for a number of vacancies at postgraduate or post-doctoral level funded by a major collaborative grant under the European Community's SCIENCE Programme for a period of 3 years to investigate the control of gene expression by steroid hormones. The project concerns the characterization of insect steroid (ecdysteroid) receptors, the receptor genes and hormone-responsive genes in the fruitfly *Drosophila melanogaster* and the blowfly *Calliphora vicina*. The collaborating groups are those of Prof. J. Koolman (Marburg). Dr. J-A. Lepesant (Paris) and Dr. L. Dinan (Exeter). The vacancies in Exeter and Marburg are suitable for applicants with a background in biochemistry/organic chemistry or immunology and the vacancy in Paris is appropriate for a molecular biologist. Previous research experience of steroid hormones, receptors, monoclonal antibody production, modern protein purification methods or molecular biological techniques would be an advantage. Applicants must be nationals of one of the twelve European Community countries. Salaries will be on the national scale appropriate for the country, with allowance for age and experience. Travel funds are available for research visits and discussion meetings between the collaborating laboratories. Applications (3 copies), including details of previous experience, a list of all publications, copies of publications (if available), the names of 3 referees and stating which post(s) you wish to be considered for, should be sent as soon as possible to **Dr. L. Dinan, Dept. Biological Sciences, University of Exeter, Perry Road, Exeter, Devon, EX4 4QG. U.K.**, from whom further particulars may also be obtained (Tel: [0392] 264605 or 264603, Fax: [0392] 263108, Telex: 42894 EXUNIV G). (1635)A

THE UNIVERSITY OF THE SOUTH PACIFIC

INSTITUTE FOR RESEARCH, EXTENSION AND TRAINING IN AGRICULTURE

The Institute (IRETA) as implementing agent for five projects contained within the Pacific Regional Agriculture Development Programme funded under the Third Lome Convention by the European Community is seeking applicants for the following posts located in the countries shown.

The Institute is located on the University's Alafua Campus near Apia in Western Samoa and serves eleven countries in the South Pacific Region. The agronomist (Kiribati) will be located within the University's Atoll Research and Development Unit in Tarawa and the agronomist (Vanuatu) will be located in Port Vila and will work in collaboration with the Ministry of Agriculture, Vanuatu, utilising facilities at their Tagabe Research Station.

Applicants for all these posts must be citizens of one of the EEC member states or of an African, Caribbean or Pacific country signatory to the Lome III Convention; must have a good command of written and spoken English; and should have an understanding and sympathy for the cultural, social and economic situation in the countries of the region which are basic to agricultural development. Appointees will be responsible for the technical and financial implementation of their project/sub-project to the Director of IRETA.

Project 1 – Intensified self-sustainable food cropping system
FELLOW IN AGRONOMY/ATOLL AGRICULTURE (KIRIBATI) (Post 89/51)

Responsibilities will include reviewing existing literature and developing, in collaboration with national departments of Agriculture and other scientists at Alafua, a programme of research and development to improve food crop production in the atoll environment utilising improved methods of compost making and irrigation; and transferring those developments to other atoll countries by demonstration and the production of reports, extensions, publication and scientific papers.

Applicants should be senior agriculturalists who: possess a degree in agriculture or other suitable biological science with postgraduate qualifications in a field of agriculture preferably related to crop production in the tropics; have at least ten years and preferably more years of experience of tropical agriculture, preferably in the humid tropics with emphasis on crop production – experience in an atoll environment would be an advantage; be prepared and motivated to work with the minimum of supervision in isolated conditions.

FELLOW IN AGRONOMY/POLYNESIAN CULTURE (WESTERN SAMOA) (Post 89/52)

Responsibiliies will include reviewing published literature and current research and developing, in collaboration with Soil Scientists at Alafua, a five year programme of research to evaluate and demonstrate the extent to which nitrogen fixing coppiced trees can be used to sustain food crop yields and the comparative labour inputs and control of soil erosion achieved in such systems and traditional shifting culture; transferring the technology developed by reports, workshops and extension publications.

Applicants for this post should be senior agriculturists who: possess a degree in agriculture or other appropriate biological subject with a postgraduate qualification in the field of agriculture, preferably related to crop production in the tropics; have at least ten years work experience of tropical agriculture, preferably in the humid tropics with emphasis upon crop production. Experience with agro-forestry and mixed cropping would be an advantage as would experience in the Pacific.

FELLOW IN AGRONOMY/MELANESIAN AGRICULTURE (VANUATU) (Post 89/53)

The appointee will be required to review the literature into the systems of food cropping and the maintenance of fertility, current research in Melanesia and the recommendations of the EC Consultant and develop a programme of research to diversify and sustain food cropping systems and settlement in logging areas in collaboration with soil scientists at Alafua and the National Departments of Agriculture and to transfer the technology development by appropriate extension procedures.

Applicants for the post should be senior agriculturists who: possess a degree in agriculture or other suitable biolgical subject with postgraduate qualifications in a field of agriculture preferably in the humid tropics and with the emphasis upon agro-forestry – preference will be given to those with experience of tropical root crop production; have a good crop experimentation background and record.

Project 2 – Provision of a Regional Tissue Culture Service
FELLOW IN TISSUE CULTURE (WESTERN SAMOA) (Post 89/54)

The appointee will be responsible for the existing tissue culture unit, for its further development and for the training of staff and students to provide a tissue culture service for the region, maintaining a germplasm collection of root crops, multiplying and disseminating improved cultures and developing methods of tissue propagation for crops of regional importance.

Applicants for the post should be experienced scientists who: possess a degree in biological sciences with a postgraduate qualification connected with plant tissue culture; have extensive experience with tissue culture and its use in germplasm collection, curation, propagation, its use in the production of disease free material and preferably of virus indexing. Experience with tropicl crops would be a distinct advantage as would previous overses tropical experience.

JUNIOR FELLOW IN TISSUE CULTURE (WESTERN SAMOA) (Post 89/55)

The appointee will be responsible to the Senior Fellow in Tissue Culture and assist him/her with the programme of work taking responsibility for the part of the programme delgated to him/her. Applicants for this post should be scientists who: possess a good first degree in Botany, Horticulture or Agriculture; have experience of plant tissue culture (preference wil be given to those with a postgraduate qualification associated with tissue culture); have overseas experience in the humid tropics and/or experience of working with the tissue culture of tropical crops.

Project 3 – Provision of a Regional Biometrical Service
FELLOW IN APPLIED STATISTICS/BIOMETRICS (WESTERN SAMOA) (Post 89/56)

The appointee will be responsible for the provision of a Regional Biometric Service comprising a consultancy service in the design and analysis of experiments and the use of micro-computers to the national departments of agriculture in the region and the preparations and delivery of formal and non-formal courses in applied statistics for use in agriculture.

Applicants for this post should be scientists who: possess a good first degree in Agriculture, Science or Mathematics and a higher degree in Agricultural Experimentation and Statistics – experience in the fields of experimental design and statistical analysis and in the use of microprocessors and the software appropriate to the IBM/AT machines is essential; have at least five years working experience — overseas experience preferably in the tropics and experience with tropical crops would be a distinct advantage.

Salaries and Conditions of Service

Salary will be in accordance with qualifications and experience in the Junior Lecturer/Lecturer II/Lecturer I/Senior Lecturer salary scales, and depending on work station, as follows

	Kiribati Aust $	Western Samoa Tala	Vanuatu Vatu
Junior Lecturer	14,154 – 15,882	24,353 – 27,324	1,144,784 – 1,284,508
Lecturer II	16,515 – 18,479	28,414 – 31,793	1,335,719 – 1,494,608
Lecturer I	19,132 – 26,001	32,917 – 44,735	1,547,365 – 2,102,962
Senior Lecturer	26,833 – 31,354	46,166 – 53,946	2,170,247 – 2,535,940

The positions have been designated for inducement allowance, depending on work station and level of appointment, as follows:

	Kiribati Aust $	Western Samoa Tala	Vanuata Vatu
Lecturer	26,001	44,735	2,102,962
Senior Lecturer	31,354	53,946	2,535,940

The University also provides gratuity amounting to 15% of basic salary; appointment allowance; partly furnished accommodation at a rental of 12.5% of basic salary; and a contribution of 10% of basic salary towards an approved superannuation scheme. Appointments will be for a contract period of two years and may be renewed by mutual agreement.

Further information may be obtained from the Secretary (Alafua Campus) (Telephone 21671; Telex 251 USP SX; Fax (685) 22933).

Candidates should send THREE COPIES of their curriculum vitae with full personal particulars, names and addresses of three referees and date of availability. In order to expedite the appointment procedure applicants are advised to ask their referees to send confidential reports direct to the University without waiting to be contacted. Applications should be sent to the **Secretary, School of Agriculture, University of the South Pacific, Alafua Campus, Private Mail Bag, Apia, Western Samoa, to reach him no later than 15 October 1989.** Applicants resident in the UK should also send a copy to the **Appointments Officer, Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.**

U C L A

Department of Physiology

CARDIOVASCULAR TENURE TRACK POSITIONS

Applicants are being sought in two areas: (1) *Vascular* — Emphasis on molecular genetic, endothelial-smooth muscle interaction or structural-functional relations. (2) *Cardiac* — Emphasis on molecular biology with either investigation of hypertrophy-growth or membrane interactions (e.g. channel formation). The recruitment is cooperative among the Departments of Physiology, Medicine, and the Cardiovascular Research Laboratory at the UCLA School of Medicine. Please respond, with curriculum vitae, to:

G.A. Langer, M.D.
Cardiovascular Research Lab. A3-381 CES
UCLA School of Medicine
10833 Le Conta Avenue
Los Angeles, CA 90024-1760

The University of California is an Affirmative Action/Equal Opportunity Employer. (NW4273)A

UNIVERSITY OF BATH
SCHOOL OF CHEMISTRY

POSTDOCTORAL RESEARCH OFFICER

"Advanced Inorganic and Bioinorganic Materials"

Applications are invited for the above post for work with Dr S Mann on the synthesis and characterization of advanced inorganic and bioinorganic materials using molecular recognition processes. The candidate should preferably have interests in inorganic bioinorganic and solid state chemistry, biomineralization, or crystal growth and materials science.

Starting salary will be up to £11,088. The appointment is for three years.

Application forms may be obtained from the **Personnel Office, University of Bath, Claverton Down, Bath BA2 7AY** or 'phone Bath (0225) 826095 quoting ref no: 89/286. Closing date: 5.10.89. (1620)A

DEPARTMENT OF BIOCHEMISTRY

University of Geneva

FACULTY OF SCIENCES

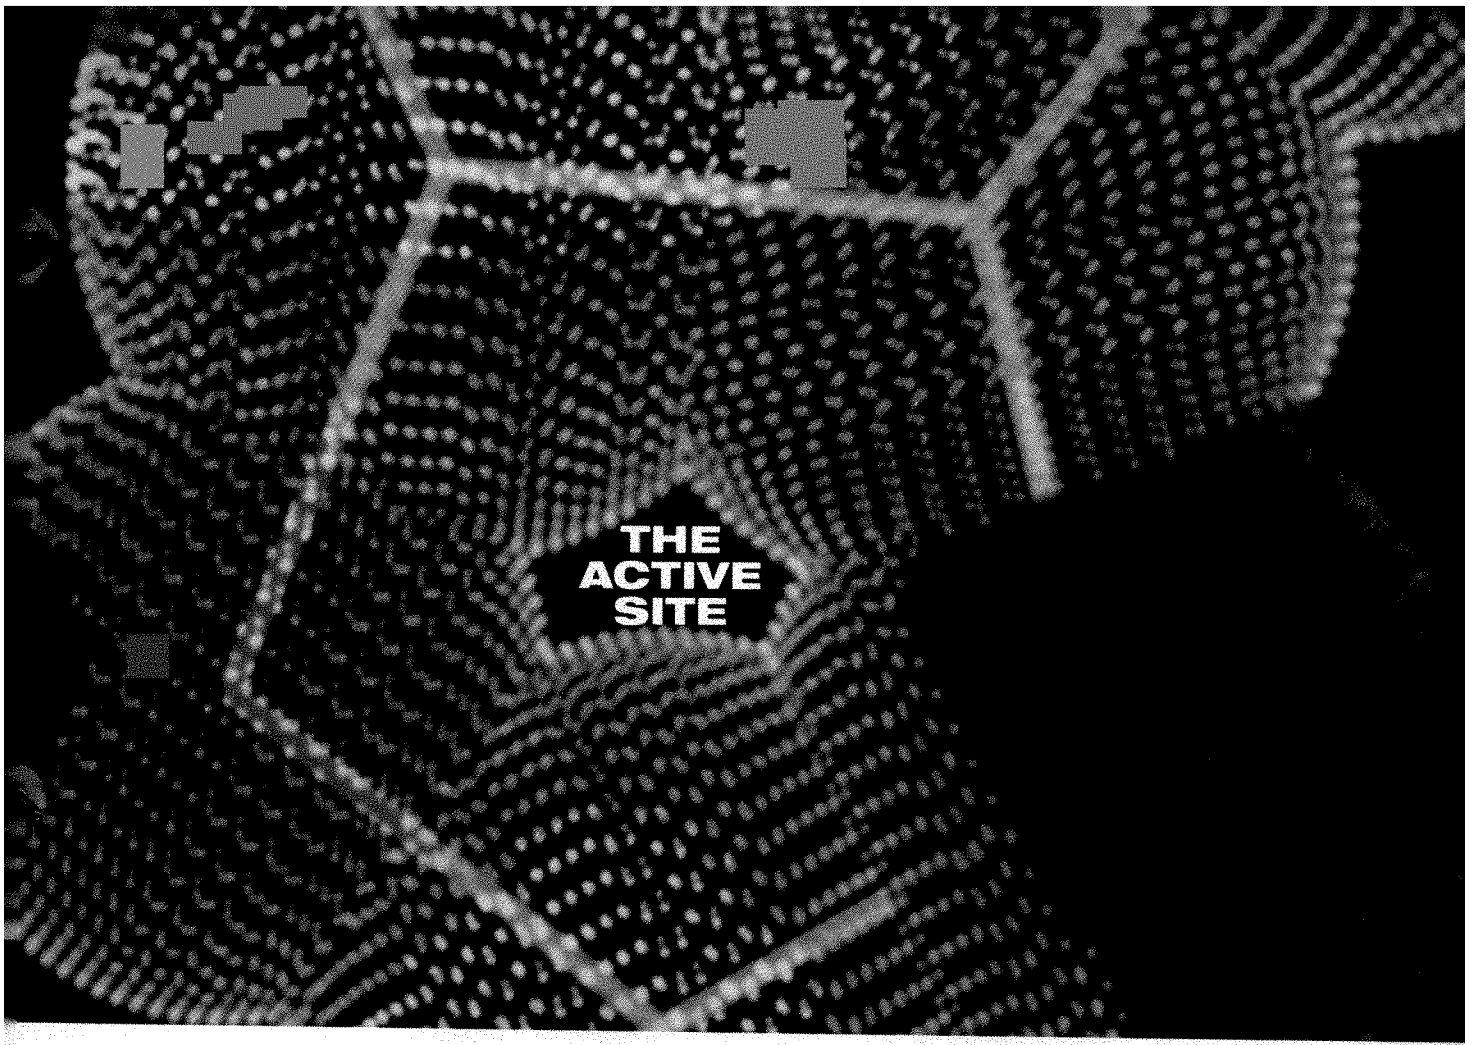
A full-time position has been opened for a scientist capable of directing a strong research program in biochemistry. All fields of research will be considered. The position will be filled at the rank of Full Professor, or possibly at a lesser rank for promising younger candidates.

Teaching at undergraduate and graduate levels will be required. The language of instruction is French, but a period of adjustment to this requirement can be granted

The proposed starting date is October 1990, but this is negotiable.

Applications should be sent by November 15, 1989 to: **Secrétariat de la Faculté des Sciences, Université de Genève, 20, quai Ernest-Ansermet, CH-1211 GENEVA 4, Switzerland,** from whom additional information can also be obtained.
(W6464)A

ROYAL HOLLOWAY AND BEDFORD
NEW COLLEGE
University of London



SCHOOL OF LIFE SCIENCES
POSTDOCTORAL BIOCHEMIST/BIOLOGIST

A Postdoctoral candidate is required for a 3-year AFRC-funded project aimed at examining the nature and function of peroxidase-catalyzed crosslink formation between extension precursors derived from suspension cultured plant cells. The effects of pathogens and elicitors on cell wall extension and specific peroxidase are also to be examined. The successful applicant will join a large and vigorous plant research group in the School of Life Sciences, Biochemistry Department. The appointment is to be made from November 1st 1989 (flexible) at the RA 1A scale on or around £14,031 including London allowance, depending on age and experience. For informal enquiries please contact Dr P.M. Dey, Tel: 0784 434455 ext. 3542. Formal applications with c.v. and the names and addresses of two academic referees should be submitted as soon as possible to the **Personnel Officer, Royal Holloway and Bedford New College, Egham Hill, Egham, Surrey TW20 0EX.** (1616)A

Virology Postdoctoral Fellow

University of Nebraska — Lincoln

Position available January, 1990, to work on the molecular biology of Bovine Viral Diarrhea virus (BVDV, Flaviviridae). The research aim is to characterize the molecular basis for the differential mode of interaction of cytopathic and non-cytopathic BVDV strains with the host cell. Requires Ph.D. in Microbiology, Molecular Biology or Biochemistry. Experience in molecular biology and protein biochemistry is desired. Send curriculum vitae and three letters of reference before November 1, to: **Dr. Ruben Donis, Department of Veterinary Science, University of Nebraska — Lincoln, Lincoln, NE 68583-0905.** *Affirmative Action/Equal Opportunity Employer.*

SECTION LEADER
MEDICINAL CHEMISTRY

Terlings Park in Harlow is one of the most advanced facilities of its kind in the world, and is at the heart of euroscience research for Merck, Sharp nd Dohme, the world's leading pharmaeutical company.

his is a rare opportunity for a chemist ith around 10 years' postdoctoral xperience to play a key role in leading novative drug discovery programmes cussing on disorders of the central nervus system. Reporting to the Director of edicinal Chemistry, your prime responbilities will be to lead a dedicated team of ostdoctoral and postgraduate synthetic ganic chemists and to collaborate with ientists in biological disciplines.

reativity and innovative application of ganic synthesis to drug design, together ith proven ability to utilise modern methods of structure-activity analysis, are essential scientific qualities for this demanding role. You should already have established a significant track record of accomplishments in Medicinal Chemistry, most recently within the Pharmaceutical Industry.

As well as a high profile role in a key area of the company's development, and the superb facilities and rural location, there is an excellent package designed to attract someone of your standing including generous relocation assistance and prestige car.

Write with a full CV including current salary details to Cathy Woodbine, Personnel Manager, Merck, Sharp & Dohme, Neuroscience Research Centre, Terlings Park, Eastwick Road, Harlow, Essex CM20 2QR.

DOHME

Neuroscience Research Centre

DUBLIN CITY UNIVERSITY

LECTURESHIP IN BIOLOGICAL SCIENCES

Applications are invited in the following areas:

- Biochemical Engineering
- Biochemistry
- Microbiology
- Bioprocessing
- Animal Cell Biotechnology

The successful candidates will be involved in teaching (BSc. honours courses in Biotechnology and Analytical Science) and research and will have an opportunity for research involvement in the National Cell and Tissue Culture Centre and the National Bioprocessing Unit, which have recently been established at Dublin City University by BioResearch Ireland, the National Biotechnology Programme.

Candidates should be well qualified academically and have appropriate research and/or industrial experience.

Salary Scale

Assistant Lecturer	£13,637 - £17,009
Lecturer	£17,758 - £26,154

Application forms and further details are available from the Personnel Office, Dublin City University, Dublin 9. Tel. 370077. Closing date for completed applications is Friday 13th October 1989. (1655)A

UNIVERSITY OF BATH
School of Chemistry

POSTDOCTORAL RESEARCH OFFICER

"Computer Simulations of Inorganic Crystal Growth at Protein and Membrane Surfaces"

Applications are invited for the above post for work with Drs S C Parker, D J Osguthorpe and S Mann on the computer modelling of interfaces comprising protein and inorganic crystal surfaces. The candidate should preferably have interests in molecular modelling studies of biological molecules or inorganic solids.

Starting salary will be up to £11,088. The appointment is for two years.

Application forms may be obtained from the **Personnel Office, University of Bath, Claverton Down, Bath BA2 7AY** or 'phone Bath (0225) 826095 quoting ref no: 89/287. Closing date: 5.10.89. (1619)A

FACULTY POSITIONS
SECTION OF IMMUNOBIOLOGY
YALE UNIVERSITY

The Section of Immunobiology, a multidisciplinary group working collaboratively on basic problems of T cell development, activation, and function, seeks applicants for several faculty positions at the level of assistant professor in the general area of immunobiology.

Qualified applicants in all areas of Immunology are invited to apply and would be expected to develop an independent research program using molecular, cell biological or biochemical approaches to immunobiological problems. We are particularly interested in people active in the areas of T cell development, regulation of gene expression, signal transduction, and protein traffic in cells of the immune system. They will also be expected to particpate in departmental teaching at primarily the graduate level.

Candidates should submit a curriculum vitae with a summary of present and future research interests, and request that three letters of recommendation be sent, all of which must be received at the below address no later than November 15, 1989.

Dr. Richard Flavell
Chairman, Section of Immunobiology
Yale University School of Medicine
310 Cedar Street, 424 FMB
P.O. Box 3333
New Haven, CT 06510

Women And Minority Candidates Are Encouraged To Apply
(NW4161)A

MOLECULAR DEVELOPMENTAL BIOLOGY
UNIVERSITY OF SOUTHERN CALIFORNIA

The Molecular Biology Section of the Department of Biological Sciences invites applications for two tenure-track faculty positions, at a junior or senior level. The successful candidates will be expected to establish and maintain vigorous, independent research programs in **Molecular Developmental Biology**. The candidates will also be expected to participate in the teaching programs of the Department at the undergraduate and graduate level, and to participate in the further development of the Molecular Biology Section.

Applicants should send a current curriculum vitae, a statement of research plans, and the names of three references by October 30, 1989 to:

Search Committee Chairman
Molecular Biology Section
SHS 172, MC 1340
University of Southern California
Los Angeles, CA 90089-1340

The University of Southern California is an equal opportunity employer. (NW4270)A

POSTDOCTORAL — CALTECH

Postdoctoral research associate position available to investigate specificity determinants for enzyme catalyzed protein modification. Experience in protein purification, radioisotope handling and enzyme kinetics desired. Send CV, description of relevant experience and 3 references to **Dr. Barbara Imperiali, Chemistry, 164-30, Caltech, Pasadena, CA 91125. (FAX: 818-568-8824).** Caltech is an AA/EO employer; women and minorities are encouraged to apply. (NW4246)A

BP VENTURE RESEARCH FELLOWS AND ASSISTANTS

Department of Geology **(UNIVERSITY OF BRISTOL)**

Department of Applied Mathematics and Theoretical Physics **(UNIVERSITY OF CAMBRIDGE)**

Dr. H. E. Huppert (Cambridge) and Professor R. S. J. Sparks (Bristol) are investigating the novel and fundamental effects of particles on fluid flows with applications to sediment transport, volcanism and industrial processes. The research will involve both theoretical and experimental investigations. The following positions are available.

* Two post-doctoral fellowships (three years)
* Two post-graduate research assistants

Backgrounds such as fluid mechanics, geology, sedimentology, physics and applied mathematics are appropriate. The research will emphasise geological aspects at Bristol and fluid mechanics at Cambridge with close links between the two groups.

Salaries will depend upon relevant experience and status.

Applicants should send a curriculum vitae and the names of two or three referees to either the Personnel Office, Senate House, Tyndall Avenue, Bristol University, Bristol BS8 1TH or directly to Dr. Huppert in the Department of Applied Mathematics and Theoretical Physics, Silver Street, Cambridge CB3 9EW. Further particulars can be obtained from either source.

Bristol University applicants should quote reference number A697 Tel. No. (0272) 303136.
Cambridge University applicants should quote reference number HHI Tel. No. (0223) 337853 Fax No. (0223) 337918.

FACULTY POSITION IN ORGANIC OR INORGANIC CHEMISTRY

The Department of Chemistry at Washington University in St. Louis invites applications for a tenure-track position, effective September, 1990. While the particular area of focus within organic and inorganic chemistry is open, a research program with a substantial synthetic component is sought. Primary consideration will be given to applicants at the Assistant Professor level, but candidates with distinguished records will be considered for higher-level appointments. Candidates should submit, by November 1, 1989, a curriculum vitae and a concise, specific statement of research plans, and arrange to have three letters of reference sent to. **Professor Peter P. Gaspar, Chairman: Organic-Inorganic Search Committee, Department of Chemistry, Washington University, St. Louis, MO 63130.** Washington University is an Equal Opportunity, Affirmative Action Employer, and employment eligibility verification will be required of the successful candidate.

(NW4168)A

UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSIOLOGY

Applications are invited for a post-doctoral research assistant post with Professor Matthews' group on the central mechanisms of trigeminal pain. The post is funded for 2 years by the M.R.C. and is available from October 1st. The salary is in the range £10,458 to £16,665.

For further information, please contact Professor B. Matthews, Department of Physiology, The Medical School, University Walk, Bristol BS8 1TD. Tel: (0272) 303459 or 303460.

Please quote reference A713.

LONZA

As a subsidiary of the Alusuisse Company, we are a versatile and internationally recognised chemical concern with worldwide contacts
The Biotechnology department of our Organic Intermediates and Fine Chemicals division, located in Visp in the Swiss Alps, has a position available for an

Analytical Biochemist

The sucessful candidate will be expected to interact closely with our multidisciplinary project teams, to provide them with specialist analytical services, and to develop new methods when needed

The ideal candidate will therefore have
- A degree or equivalent in Biochemistry, Chemistry or a related subject (Not a PhD)
- Extensive experience in HPLC, especially as applied to biochemical problems
- Familiarity with other analytical techniques such as electrophoresis and TLC
- Initiative and the motivation to work independently, yet within a team
- Good communication skills

In return we offer
- Excellent laboratory and library facilities
- Modern employment conditions
- An attractive benefits package

Please send your written application, including a CV to

LONZA AG, Walliser Werke

UNIVERSITY OF CAMBRIDGE SCHOOL OF CLINICAL MEDICINE

Post-Doctoral Position
in Human Molecular Genetics
funded by the Wellcome Trust

Applications are invited for this position which is funded for up to 5 years to work on inherited disorders of metabolism in man.
The research will primarily involve the characterization and mapping of cDNA clones that relate to iron-inducible proteins. The scientist will also participate in a group involved in the structural and functional characterization of mutations in other genes that are responsible for inherited disorders of carbohydrate metabolism and haem biosynthesis.
Salary is in the range of £14,169 to £16,665 per annum.
Applicants should send 3 copies of their curriculum vitae and apply for further particulars to **Professor T M Cox, Department of Medicine, Level 5, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QQ.** (1639)A

University of Oxford, Institute of Molecular Medicine, John Radcliffe Hospital, Oxford OX3 9DU

COLLAGEN GENETICS

Two new posts are available in the Collagen Genetics Group for the development and implementation of new techniques for the detection of collagen gene mutants in human disease. The posts are funded by Action Research for the Crippled Child.

Post-doctoral Research Assistant 1A (salary scale £12,381-16,665) for 3 years to start as soon as possible.
Graduate Research Assistant 1B (salary scale £9,816-14,169) for 2.5 years to start before April 1990

Applicants for both posts should have molecular biology experience. The newly-opened Institute of Molecular Medicine houses groups working on many different areas of molecular biology related to medicine and offers unrivalled facilities, opportunities and atmosphere for this type of research.

Please send a full curriculum vitae to **Dr Bryan Sykes at the Institute or ring (0865-752404)** for further details Closing date **October 12th.** The University of Oxford is an equal opportunity employer. (1615)A

COGNITIVE PSYCHOLOGIST
The Department of Psychology, University of Rochester

anticipates filling a tenure-track position in cognitive psychology for the 1990-91 academic year. Candidates may have research interests in any area of cognition. The ability to establish and maintain an independent and outstanding program of research and to make major contributions to both undergraduate and graduate teaching are key considerations. Women and minority candidates are particularly encouraged to apply.

Send curriculum vitae, statement of research interests, and three letters of recommendation to: **Dr. Michael K. Tanenhaus, Cognitive Search Committee, Department of Psychology, University of Rochester, Meliora Hall — River Campus, Rochester, NY 14627.** Deadline for receipt of application materials is December 1, 1989

The University of Rochester is an Equal Opportunity/Affirmative Action employer. (NW4250)A

United Medical and Dental Schools of Guy's and St Thomas's Hospitals

RESEARCH ASSISTANT

required to study the regulation of calcium channels in isolated heart cells in a well-equipped laboratory specialising in the use of patch-clamp techniques, in combination with flash-photolysis of 'caged' compounds to generate concentration 'jumps' of intracellular messengers Knowledge of electrophysiological techniques an advantage Preferably candidates should have a Ph D degree but those with good (minimum 2.1) honours degree considered. Appointment for a period of two years

Salary range £9,816-£16,665 plus £1,650 LWA according to age, qualifications and experience. For further information please contact Dr A Gurney on 01-928 9292 ext 3710.

Applications with full CV and names and addresses of two referees to the **Personnel Officer, UMDS, St Campus, Lambeth Palace Road, London SE1 7EH** by 12 October 1989 quoting reference STH/PHAR/413 (1643)A

SHAPING YOUR FUTURE

PSC-CFP

The People

The people who work for Forestry Canada in Sault Ste. Marie, enjoy a career in a multidisciplinary institution that encompasses a wide range of research activities and technology development. This regional centre specializes in research in forest production, protection, environment and utilization. It also houses the Forest Pest Management Institute which conducts research in biorational and chemical control agents. To ensure that all candidates have every chance on an equal basis, we encourage equitable participation by women, aboriginal peoples, members of visible minority groups and persons with disabilities.

Your Choice

Research Entomologist - Population Ecologist

($32,948 - $61,284)

Carry out all aspects of a research program on the dynamics of forest insect pests in Ontario including planning, development, implementation and reporting. Conduct field sampling, experimentation and laboratory studies such as the use of computer simulation modeling and GIS. Perform project activities that include biological control/parasitoid ecology, biometeorology, chemical ecology (pheromones), insect physiology and population dynamics.

Your Contribution

A doctoral degree in biology, preferably entomology, with specialization in quantitative analysis of population change or a lesser degree with evidence of research experience and productivity equivalent to a doctoral degree. Employment experience in this field desirable, but not essential.

Knowledge of the English language is essential. Preference will be given to Canadian citizens.

Send your application, reprints of significant publications and a minimum of three references by October 31, 1989, quoting reference number: S-89-31-5871-47JG-G26 to: Joan Girling, Public Service Commission of Canada, 171 Slater Street, Ottawa, Ontario K1A 0M7.

Personal information is protected under the Privacy Act. It will be held in Personal Information Bank PSC/P-PU-040

ORGANIC/POLYMER CHEMIST

$31,525 p.a. to $45,699 p.a.

DIVISION OF CHEMICALS AND POLYMERS
CLAYTON, VICTORIA.

GENERAL: The CSIRO Division of Chemicals and Polymers aims to develop new technologies to support the growth in Australia of chemical, polymer and water/wastewater treatment industries which are competitive in domestic and international markets. The Division employs approximately 170 people of whom over 60 are professional scientists. It is located in modern well-equipped laboratories at the CSIRO Clayton site

THE JOB: We are seeking an organic or polymer chemist to synthesise and evaluate novel ion exchange resins and polymeric flocculants in our water and wastewater treatment program. The synthetic work will involve polymerisation and polymer modification reactions. Evaluation of ion exchangers will include physico-chemical measurements and laboratory-scale simulation of industrial wastewater treatment processes

The appointee will work within broad guidelines and will be expected to make original contributions to the project

THE PERSON: Applicants should possess a PhD degree or equivalent qualification in synthetic organic or polymer chemistry, together with a demonstrated ability to conduct original research The ability to work as a team member is essential, as are good written and oral communication skills

A knowledge of chemical engineering principles or experience of pilot-scale testing would be an advantage

TENURE: A fixed term appointment of 3 years, with Australian Government Superannuation benefits available.

FURTHER INFORMATION:

- An outline of current and proposed research projects is available from Dr R Eldridge, phone (03) 542 2419
- Selection criteria and job description are available from Ms J. Pickering, phone (03) 542 2483

APPLICATIONS: Stating relevant personal and professional details including the names and addresses of at least two referees and quoting reference no 89/14 should be addressed to.

The Chief,
CSIRO Division of Chemicals and Polymers,
Private Bag 10,
Clayton, Vic. 3168

IMMUNOLOGISTS

The University of Washington seeks highly-qualified applicants for tenure-track appointments in the newly formed Department of Immunology. Applicants must have a Ph.D. or M.D. degree, appropriate post-doctoral training, and must have demonstrated their ability to establish strong independent research programs in immunobiology. We invite applications from molecular and cellular immunologists, particularly those interested in applying molecular genetic techniques to the elucidation of mechanisms of antigen recognition, signal transduction, or lymphocyte development. The Department of Immunology offers superb new laboratory space with access to flow cytometry, biopolymer synthesis, and transgenic animal facilties. Send curriculum vitae, a brief description of proposed research, and three letters of recommendation (by December 1, 1989) to **R.M. Perlmutter, M.D. Ph.D., Chairman, Department of Immunology, SL-05, University of Washington, Seattle, WA 98195.**

The University of Washington is an Equal Employment/Affirmative Action Employer. (NW4247)A

SWISS FEDERAL INSTITUTE OF TECHNOLOGY LAUSANNE
(ECOLE POLYTECHNIQUE FEDERALE DE LAUSANNE)
announces several openings for position of

FULL PROFESSOR IN EXPERIMENTAL PHYSICS

in the following domains:

- **Physics of electronic materials**
- **Physics of semicrystalline solids**
- **Surface physics/Surface science**
- **Physics for biomedical engineering**

Teaching is given in French.

Applications deadline: November 30th, 1989

The successful candidates are expected to start their activities in summer–fall 1990.

For more information, and application, write to:

CE-Ecublens, CH 1015 Lausanne — Switzerland

(W6497)A

DEPARTMENT OF VISUAL SCIENCE
Institute of Ophthalmology
Judd Street, London, WC1H 9QS

TECHNICAL RESEARCH OFFICER

This post is for candidates with experience in biomedical laboratory science to assist the Head of Department in the day-to-day running of the laboratories, monitoring accounts and processing orders. It will carry considerable responsibility and require both technical and administrative expertise. The Department is expanding and developing an extensive research programme in investigative ophthalmology and visual neuroscience.

The starting date will be Oct/Nov 1989. The initial salary will be £15,623 (plus £1,267 LA) on the scale £14,444 – £16,897.

BIOMEDICAL RESEARCH TECHNICIANS

We are pleased to invite application for three research posts in our biomedical research programme. One of these is tenured, one is for five years on an externally-funded research progrmme grant and the other is for three years and would be suitable for a recent graduate interested in taking on a part-time PhD. Our work involves a wide range of techniques and a broad experience in biomedical science and an interest in computing would be helpful.

The salaries will be in the range £6,686 – £10,148 (plus LA) according to age and experience.

Applicants should send a full curriculum vitae with names of two referees to **Professor A. M. Sillito at the address above** from whom further details can be obtained. (01-387 9621 ext 258).

PORTSMOUTH POLYTECHNIC

School of Pharmacy and Biomedical Sciences

POSTDOCTORAL POSITION

SERC-funded position immediately available for design and synthesis of sequence-specific DNA-binding ligands. A strong background in synthetic chemistry is essential and an interest in molecular modelling and drug-DNA interactions helpful. Initial contract for one year with likelihood of extension for further two. Starting salary £11,130. Send curriculum vitae and three letters of reference to **Dr. David E. Thurston, School of Pharmacy and Biomedical Sciences, Portsmouth Polytechnic, King Henry I Street, Portsmouth PO1 2DZ.** (1608)A

Closing date: 4 October 1989

Portsmouth Polytechnic pursues a policy of equality of opportunity. Applications are particularly welcome from people with disabilities

NEUROSCIENCE IN TOXICOLOGY

A leadership role in Neurotoxicology for an experienced Neuroscientist

Neurotoxicity is of growing importance in the safety evaluation of chemicals and consequently ICI has created the new post of Senior Neurotoxicologist with the objective of strengthening existing scientific expertise in this area. This position offers a challenging opportunity for someone already working in neurotoxicity, or for a more basic neuroscientist who wishes to utilise their skills and knowledge in an applied field

The Senior Neurotoxicologist will be responsible for all neurotoxicity studies and the supervision of follow-up experiments to investigate mechanisms of neurotoxicity and to establish the relevance of experimental data to man. He or she will be the leader of an existing team of post-doctoral scientists with expertise in electrophysiology, neuropathology and biochemistry. The person appointed will be encouraged to establish an international reputation in neurotoxicity through external collaboration and the publication of results

Good communication skills will be required in order to act as an advocate on neurotoxicity issues concerning ICI products and to contribute to the development of Regulatory Science Guidelines. The Senior Neurotoxicologist will be expected to develop a close liaison with ICI Businesses on an international basis, in order to provide expert advice and opinion.

Candidates should be in the range 35-45 years old and able to demonstrate a broad range of knowledge in the neurosciences, with the ability to integrate the work of various disciplines. Applications will be considered from scientists working in any sector of neurobiology, including the clinical neurosciences.

The Senior Neurotoxicologist will join ICI's Central Toxicology Laboratory at Alderley Park in Cheshire, which is internationally recognised as a scientific centre of excellence in research toxicology With four hundred staff, CTL provides toxicological expertise in support of ICI Businesses worldwide and this is reflected in the excellent facilities and equipment available. The Laboratory is adjacent to the ICI Pharmaceuticals Research Centre, which offers the opportunity for interaction with a thriving bioscience community.

Opportunities exist for promotion within the Laboratory either in a scientific or management role. Furthermore, CTL as a central facility, provides a window on ICI, giving a broad view of longer-term career opportunities across the ICI Group The remuneration package for this position will be competitive and reflect the skills and experience of the candidate. Starting salary will be in the range £25-27,000.

In addition, we also offer a profit sharing bonus, free health insurance, share options, a contributory pension scheme and, where appropriate, generous assistance with relocation expenses to this area which boasts reasonably priced housing and excellent educational facilities. CTL is located in an attractive parkland site in rural Cheshire, the location is well served by major road/rail networks and offers a high quality of lifestyle.

To apply please write, enclosing a comprehensive Curriculum Vitae and quoting reference N/MT to: Personnel Section, ICI Central Toxicology Laboratory, Alderley Park, Macclesfield, Cheshire SK10 4TJ.

The closing date for applications is 6/10/89.

ICI is an Equal Opportunities employer.

World Class

UNIVERSITY COLLEGE LONDON

POSTDOCTORAL BIOCHEMIST
5 Years

Following an award of £1.4m from the Wellcome Trust to expand our NMR spectroscopy work we are looking for a biochemist to join our research group. Our work is centred around brain metabolism and function with a particular interest in hypoxic-ischaemic damage in human neonates. The work involves collaboration between the Departments of Physiology (Dr S. Wray), Paediatrics (Prof. E.O.R. Reynolds) and Medical Physics (Dr. D. Delpy), at UCL, allowing a strong interdisciplinary approach to this subject. A postdoctoral biochemist is sought to help develop work in the area of brain biochemistry. This could be related to the following areas: cerebral development, neurotransmitters, cerebral protective agents, mitochondrial function, membrane biochemistry. We have excellent facilities and long term support from the Wellcome Trust.

The post is on the 1A research assistant scale (range 10,458 to 16,665) and is for 5 years. To apply please send a full CV to **Dr S. Wray, Physiology Department, University College London, Gower Street, London WC1E 6BT (tel: 01-387 7050 ext. 3225)**, to whom informal enquiries can also be made. (1650)A

UNIVERSITY OF OXFORD

UNIVERSITY LECTURESHIP IN STRATIGRAPHY
in association with St. Peter's College

Applications are invited for a university lectureship, to be filled from 1st October 1990 in the general field of stratigraphy in which the lecturer may have research interests in any area within the discipline. The lecturer would be expected to have strongly field-based research, knowledge of modern seismic stratigraphy methods and the ability to develop new concepts in stratigraphy. Stipend will be according to age on the scale £10,458 to £21,852 p.a., together with membership of the University's Superannuation Scheme. The lecturership, open to men and women, will be held in conjunction with a Tutorial Fellowship at St. Peter's College. Further particulars may be obtained from **Professor J.F. Dewey, Department of Earth Sciences, Parks Road, Oxford OX1 3PR** to whom application (four copies, or one in the case of overseas applicants) including curriculum vitae, a statement of experience and research interests, a list of publications, and the names and addresses of three referees should be sent so as to arrive before November 30th, 1989. (1652)A

ROCHE Hoffmann-La Roche Inc

(NW4258)A

Department of Physiology and Biophysics
University of Illinois at Urbana-Champaign

Assistant Professor Protein Crystallography

Applications are invited for a tenure-track position in protein crystallography at the assistant professor level starting August 1990. Applicants are required to have a doctoral degree. The successful candidate is expected to develop a vigorous independent research program and participate in our undergraduate and graduate teaching programs. He/She will join a strong group of molecular biophysicists including two diffractionists as part of the commitment to establish an outstanding program in structural biology Salary for this 9-month appointment will be commensurate with experience and qualifications. An additional two-month summer salary may be generated from teaching or research sources.

In order to ensure full consideration applications must be received by November 15, 1989. Interviews may be conducted before November 15, 1989, but all applications received by that date will receive full consideration.

Applicants should submit a curriculum vitae, a list of publications, a short statement of future research plans, and the names of at least three references to **Dr. Andrew H.-J. Wang, Chairman, Search Committee, Department of Physiology and Biophysics, 524 Burrill Hall, The University of Illinois at Urbana-Champaign, 407 South Goodwin Avenue, Urbana IL 61801 (217/244-6637).** The University of Illinois is an Affirmative Action/Equal Opportunity Employer.

TWO RESEARCH ASSISTANTS — IB

Applications are invited for two positions to work on a collaborative project studying the intervertebral disc in scoliosis, funded by Action Research for the Crippled Child for two years. The project involves investigation of the changes in structure and metabolism of the disc using biochemical and immunohistochemical techniques and applications are invited from graduates with an interest in either of these fields. Informal enquiries can be made to Dr. P. Revell (01-377 7347) or Dr. J. Urban (0865-272500) and formal applications, including a full C.V. and the names and addresses of two referees should be made to: The Administrator, Physiology Laboratory, Oxford University, Parks Road, Oxford OX1 3PT. An Equal Opportunity Employer (1649)A

U C L A

Department of Physiology

FACULTY POSITIONS

The Department of Physiology is seeking to recruit one or more outstanding individuals at any rank, in basic research related to any area of contemporary physiology. Especially, candidates in reproduction and development, endocrinology, central nervous system, and the cardiovascular system are encouraged to apply. Successful candidates are expected to have a Ph.D. or M.D. with post-doctoral experience, to provide evidence that they can pursue a vigorous independent research program, and to participate in our teaching program. Rank for these tenure track positions will be commensurate with ability and experience.

Resources and an excellent environment exist for developing an academic career within an interactive community. Interested scientists should send their curriculum vitae, a statement of present and future research interest, and names of three references to:

Ernest M. Wright, D.Sc.
Professor and Chairman
Department of Physiology
UCLA School of Medicine
Los Angeles, CA 90024-1751

The University of California is an Equal Opportunity/Affirmative Action Employer.

(NW4274)A

UNIVERSITY OF MANCHESTER
RESEARCH ASSISTANT IN MOLECULAR GENETICS

Applications invited for this three-year post to investigate the molecular genetics of 21-hydroxylase deficiency. (For a background to the project, see EMBO J. *8*, 1393-1402). The project will focus on the molecular pathology of the disorder and will utilize the following techniques: *in vitro* mutagenesis, gene transfection-expression, pulsed field gel electrophoresis, and DNA sequencing of cloned and PCR-amplified mutant genes. Applications are welcome from both post-docs and post-graduates with a background in molecular biology, biochemistry or genetics. Experience in molecular genetics is highly desirable, but is not essential as training will be given. Initial salary range £9,816-£12,381 p.a. according to experience. The department has excellent facilities and provides a stimulating environment for acquiring postdoctoral/post-graduate experience in Human Genetics. Further information available from Dr T. Strachan (061 276 6424 or 061 276 6262). Applicants should send a C.V. plus the names of at least 2 professional referees to **Dr T. Strachan, University Department of Medical Genetics, St. Mary's Hospital, Manchester M13 0JH.** The University is an equal opportunities employer.

(1614)A

QUEEN MARY COLLEGE, UNIVERSITY OF LONDON
School of Biological Sciences

Post-Doctoral Research Assistant
in the Molecular Biology of Vision

An opportunity exists for a post-doctoral person with a training in molecular biology to join a small team working on aspects of the molecular genetics of colour vision. The work is funded by the Wellcome Trust, and the appointment would be for 3 years.

The project is concerned with a study of the photopigment molecules on which vision depends, with the main objective of correlating changes in DNA sequence with differences in the spectral sensitivity of photopigment molecules.

For further details, please contact Dr D M Hunt at the School of Biological Sciences. Application forms are obtainable by telephoning 01-975.5171 (24 hour answerphone) or send full CV and the names of two referees to **Dr D M Hunt, School of Biological Sciences, Queen Mary & Westfield College, London E1 4NS.**

(1637)A

DEPARTMENT OF ECOLOGY & EVOLUTIONARY BIOLOGY
UNIVERSITY OF ARIZONA

BEHAVIOR:

Applications are invited for a tenure-track position in the area of behavior, including its evolutionary aspects. Applicants pursuing field or experimental studies are of particular interest. High originality in research and talent as a teacher will be important criteria used in selecting among applicants. This appointment will probably be made at the assistant professor rank. Applicants should mail a curriculum vitae, statement of research plans, reprints or preprints, and arrange to have at least three letters of reference sent to **Conrad A. Istock, Department of Ecology and Evolutionary Biology, University of Arizona, Tucson, AZ. 85721.** The period for applications closes December 15, 1989. The University of Arizona is an equal opportunity/affirmative action employer. (NW4245)A

UNIVERSITY COLLEGE & MIDDLESEX SCHOOL OF MEDICINE
ACADEMIC UNIT OF DIABETES & ENDOCRINOLOGY AT THE WHITTINGTON HOSPITAL, LONDON N19

RESEARCH TECHNICIAN

Required to join a team of clinical researchers studying the determinants of heart disease in diabetes. The applicant should have experience of H.P.L.C., and the post will comprise an investigation of ways of measuring levels of catecholamines to give an index of long-term stress.

The position is initially available for 1 year. Salary is £8,645-£9,730 + £1,750 London Weighting. For further information please contact Dr John S Yudkin or Dr Peter Moult on 01-272 3070 ext. 4189. Applications to **Academic Unit of Diabetes & Endocrinology, Whittington Hospital, Archway Rd, London N19 5NF.** Closing date: 12.10.89. Ref. GM2. Equal Opportunities Employer.

(1602)A

INSTITUTE OF HYDROLOGY — WALLINGFORD

ANALYTICAL CHEMISTRY

We require an analytical chemist to assist in the analysis of natural water samples collected from a wide variety of areas in relation to pollution and water resource studies. The work involves the use of many types of modern instrumentation including ion chromatography and plasma emission spectrometry for the analysis of a wide spectrum of chemical elements.

Applicants should be educated to Degree/HNC level. The successful candidate will need to have a meticulous and organised approach to laboratory work and the ability to learn new techniques. He/She will be joining a small research group and must be able to work as a member of a team.

Salary is in the range of £9,131 to £12,223 per annum, according to qualifications and experience, and benefits include generous leave allowance and non-contributory pension scheme.

The Institute of Hydrology is a component body of the Natural Environment Research Council.

Application forms from Sue Fenton, Institute of Hydrology, Crowmarsh Gifford, Wallingford, Oxon OX10 8BB.

Tel: 0491 38800.

Closing date for receipt of application forms is 12th October 1989.

NERC is an Equal Opportunity Employer. (1641)A

Natural Environment Research Council

BIO MEGA

COMPUTATIONAL CHEMIST FOR COMPUTER-ASSISTED DRUG DESIGN

Candidate to join a team of dedicated scientists utilizing state of the art techniques in the design of biologically active molecules in a multidisciplinary atmosphere.

Qualifications:

Ph.D. or M.Sc. in Chemistry with broad based experience in molecular modelling and computational chemistry is required. Understanding of medicinal chemistry is an asset. The individual should have a high degree of creativity and motivation to analyze and solve complex problems and be able to interact with the existing staff of chemists.

Bio-Mega Inc. located in suburban Montreal, is a wholly owned subsidiary of Bochringer Ingelheim Canada, and is dedicated to applied and basic research in various fields of drug discovery.

If interested, please submit your curriculum vitae with an introduction letter in confidence to:

Mr Jacques Roux
Director of Human Resources
Bio-Mega Inc.
2100 Cunard Street
Laval (Quebec)
H7S 2G5
CANADA (NW4267)A

LUDWIG-MAXIMILIAN UNIVERSITY MUNICH, FRG

Professor (C3) of Zoology

The Department of Zoology invites applications for a tenured professorship (C3 level). The department is particularly interested in candidates with a proven research ability in the area of

Evolutionary Biology

In addition to participation in basic teaching, the successful candidate is expected to teach evolutionary biology.

Candidates should have a doctoral degree, teaching experience and Habilitation and be less than 52 years of age.

The university in particularly interested in woman applicants.

Applications including full curriculum vitae and publications should be sent by October 31, 1989 to the **Dekan der Fakultät für Biologie, Prof. Dr. Charles N. David, Theresienstr. 39, 8000 München 2, FRG.** (W6499)A

UNITED MEDICAL & DENTAL SCHOOLS OF GUY'S AND ST. THOMAS'S HOSPITALS PAEDIATRIC RESEARCH UNIT

POSTDOCTORAL/GRADUATE RESEARCH ASSISTANT OR LABORATORY SCIENTIFIC OFFICER

Required on the Guy's Campus to join a group applying modern molecular techniques to the study and diagnosis of inherited disorders.

Applicants should have a degree or HNC in Genetics, Biochemistry or a related subject. Experience with molecular biological techniques would be an advantage, but training could be provided.

The appointment will be for two years, with a salary according to standard scales, taking into account qualifications age and experience.

For further information, please contact Dr Christopher Mathew on 01-955 4653.

Please apply in writing with full CV and the names and addresses of three referees to **The Administrator, Paediatric Research Unit, 8th Floor, Guy's Tower, Guy's Hospital, LONDON SE1 9RT,** by 6th October. (1628)A

FORSCHUNGSINSTITUT BORSTEL DIVISION OF BIOCHEMICAL MICROBIOLOGY POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for an initial 2-year postdoctoral position to work on surface structures of *Chlamydia* and their role during infection. Applicants *must* have experience in working with pathogenes on the P2/P3 level and should preferably have experience in chlamydiology, molecular biology of procaryotes, or cell biology.

For further details contact Dr. H. Brade by phone (04537/10474) or by fax (04537/10404). Please send applications including CV and the names and addresses of two referees to: **Forschungsinstitut Borstel, Personalwesen, Parkallee 1-40, D-2061 BORSTEL, FRG.** (W6494)A

The University of Nottingham
Department of Botany

Post-Doctoral Research Assistant and Graduate Research Assistant

Applications are invited for these 3-year posts funded by the AFRC Plant Molecular Biology Initiative The project, supervised by Dr L G Briarty and Dr B J Mulligan, will focus on the molecular biology and genetics of nuclear coded male sterility in *Arabidopsis* Candidates for the post-doctoral post should have practical experience of molecular biology and/or genetics and an interest in applying these approaches for gene mapping. Applicants for the graduate research assistantship should have a degree in biological subject and an interest in light and/or electron microscopy.

The starting salary for the post-doctoral post will be up to point 4 on the RA1A scale (£12381) and for the graduate assistant will be point 1 on the RA1B scale (£9816).

Applications, including a CV and the names of 2 referees, should be sent by October 1989 to **Dr Bernard Mulligan, Department of Botany, University of Nottingham NG7 2RD.** Informal telephone enquiries are welcome on 0602-84848 ext. 3467. (1648)A

NATURAL ENVIRONMENT RESEARCH COUNCIL
BRITISH GEOLOGICAL SURVEY

BIOSTRATIGRAPHER

The British Geological Survey has a vacancy for a Biostratigrapher in its Biostratigraphy Research Group based at Keyworth, near Nottingham.

The successful applicant will join a multidisciplinary group supporting regional mapping programmes in Southern Britain and on the UK Continental Shelf. He/she will be expected to have experience of Mesozoic-Quaternary calcaereous nannofossils and be willing to develop parallel expertise on other microfossil groups. The appointment will be for a period of three years.

Applicants should have experience in the study of Mesozoic-Quaternary calcaerous nannofossils together with a good honours degree in Geology or a biological science and at least two years relevant postgraduate training.

Salary will be within the range of £10,678 to £14,909 depending on qualifications and experience. Terms include a generous leave allowance and a non-contributory pension scheme.

For an application form, to be returned not later than 12th October 1989, write to: **Establishments (Recruitment), British Geological Survey, Nicker Hill, Keyworth, Nottingham NG12 5GG.** Please quote reference HS/BS89/1

The Natural Environment Research Council is an equal opportunities employer. (1640)A

Natural Environment Research Council

University of Cambridge
Cavendish Laboratory
SEMICONDUCTOR RESEARCH

A number of postdoctoral positions will be available in the Semiconductor Research Group in the Cavendish Laboratory Applications are invited from candidates with relevant experience and interest in the following areas:

1 The growth of III-V semiconductors by Molecular Beam Epitaxy and subsequent processing and assessment of the grown layers and structures.

2 The fabrication of nanostructures by novel electron beam techniques. Experience in electron lithography or microscopy would be an advantage

3 The transport properties of Low Dimensional Structures and Devices, in particular high frequency properties. Experience of microwave techniques and associated circuitry will be particularly advantageous.

Persons with a background in physics, materials science or engineering are invited to apply.

Salary on a scale up to £15,372 pa.

Applications to **Mr Deakin, The Secretary, Cavendish Laboratory, Madingley Road, Cambridge, CB3 0HE. (Ref MP).** (1625)A

Faculty Position, Microbiology UCLA

The Department of Microbiology, College of Letters and Science, University of California, Los Angeles has a tenure-track position available for a molecular biologist. The primary areas of recruitment interest are, 1) molecular genetics of yeast, 2) molecular aspects of archaebacteria. A Ph.D. or equivalent as well as several years of post-doctoral experience in microbiology, molecular biology, or a related field is required, with evidence of research accomplishments and teaching abilities. The individual selected will be expected to establish a strong research program as well as participate in undergraduate and graduate student teaching. Title and salary (nationally competitive) are commensurate with qualifications and experience with preference for an entry level position. Applicants should send a letter of application, curriculum vitae, summary of research interest, relevant publications, and the names and addresses of three references to **Dr. Virginia L. Miller, Dept. of Microbiology, UCLA, 405 Hilgard Ave., Los Angeles, CA, 90024.** Deadline for applications is December 15th, 1989. UCLA is an equal opportunity employer —women and minorities are encouraged to apply. (NW4244)A

THE UNIVERSITY OF SHEFFIELD
DEPARTMENT OF PHYSICS

POSTDOCTORAL RESEARCH ASSISTANT IN THEORETICAL PHYSICS

Applications are invited for the post of SERC postdoctoral research assistant to participate in a project concerned with theoretical investigations of the microscopic dynamical behaviour and transport properties of liquids. Tenable for two years from 1 October 1989 or as soon as possible thereafter. Starting salary on IA scales in the range £10,458 - £12,381 pa. Applications, including a CV and the names/addresses of two referees, to Dr T. Gaskell, Department of Physics, The University, Sheffield S3 7RH. Reference R.938/G.

An Equal Opportunity Employer. (1653)A

The Division of Medical Genetics

Division of Oral Medicine and Pathology

RESEARCH LSO

required to work on neutrophil mediated defence against Bacteroides gingivalis and the role of specific virulence factors in opsonisation, phagoctosis and bacterial killing on Guy's Campus. Candidates should have degree in relevant subject. Some research experience in biochemistry, immunology or cell biology desirable.

Appointment for one year in the first instance, salary up to £10,650 including LW, depending on age, qualifications and experience. Further information from Dr E Odell, Dept of Oral Medicine and Pathology (01 955 4289). Applications in form of CV and names and addresses of two referees, to the **Staffing Office, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH** quoting ref: GN/OMP/396A by 12th October 1989. (1642)A

Yale UNIVERSITY

Evolutionary Biology

The Department of Biology is engaged in building an interdisciplinary program in the evolutionary sciences and organismal biology and invites applications for positions at the senior and junior levels. While outstanding scientists working in any area of evolution will be considered, areas of particular interest to our faculty include molecular approaches to population biology or phylogeny, developmental approaches to evolution, evolution of genome organization, and quantitative approaches to evolutionary problems. With building renovations now well underway, we are prepared to make several appointments as soon as possible.

We seek individuals with a strong interdisciplinary inclination, who might profit from interaction with the Department's strong programs in molecular, cell, developmental, and organismal biology, and the Peabody Museum of Natural History.

Send curriculum vitae, description of research interests and names and addresses of at least three references by January 1, 1990 to:

Evolutionary Biology Search Committee, c/o The Chairman, Department of Biology, Yale University, PO Box 6666, New Haven, CT 06511

Yale University is an Affirmative Action/ Equal Opportunity Employer (NW4216)A

POST DOCTORAL RESEARCH FELLOW
BIRKBECK COLLEGE/GUY'S HOSPITAL/DARESBURY LABORATORY

A Post Doctoral Research Fellow is needed for a collaborative project, involving groups at the above institutions.

A major aspect of the joint venture is to investigate the uptake and release of iron by serum transferrin, the central protein of iron metabolism. With respect to the above post, this will involve the development of time-resolved methods, such as stopped flow and rapid freezing for EXAFS and Solution X-ray Scattering. This position would be particularly attractive to those with interests in biophysical techniques.

The research would primarily be based at the Daresbury Laboratory, a stimulating, international, and multi-disciplinary research environment in Cheshire.

The appointment will be for 3 years only, within the salary range £12,108-£14,031 pa Applications are encouraged from scientists with research experience in one of the areas mentioned above.

Enquiries and applications should be addressed to **Dr Samar Hasnain, SERC Daresbury Laboratory, Warrington, WA4 4AD,** or to the **Assistant Secretary (Personnel), Birbeck College, Malet Street, London, WC1E 7HX. Tel: 631 6529.** Closing date is 25 October 1989.
(1654)A

DIRECTOR

Institute of Biological Chemistry
Washington State University

Applications or nominations are invited for the Director of the institute of Biological Chemistry, a research department within the College of Agriculture and Home Economics. Faculty in the Institute are dedicated to fundamental research in plant biochemistry and molecular and cellular biology. Candidates must have proven leadership ability and an internationally recognized, basic research program in plant biochemistry or allied field, commensurate with a tenured full professor position. Major responsibilities include leadership and administration of the Institute and the conduct of a highly productive and innovative research program. Ph.D. in Biochemistry, Chemistry, Molecular Biology or related disciplines is required. Applications or nominations, including accomplishments, a summary of current research, extramural grant support record, and the names, addresses, and telephone numbers of three or more references should be submitted to **Dr. Gynheung An, Chair of the Search Committee, Institute of Biological Chemistry, Washington State University, WA 99164-6340, (509) 335-4643.** Applications will be accepted until November 1, 1989, or until position is filled.

WSU is an EO/AA educator and employer. Protected groups are encouraged to apply. (NW4276)A

DEPARTMENT HEAD PATHOLOGY

UNIVERSITY OF ARIZONA HEALTH SCIENCES CENTER

The University of Arizona College of Medicine is seeking a nationally renowned, highly qualified academic pathologist to head the Department of Pathology in Tucson, Arizona.

The College of Medicine has a twenty-two year history of rapid growth in every aspect of its mission — teaching, research, patient care, and community service. The recently appointed dean, James E. Dalen, M.D., is committed to excellence. Significant opportunities exist for the new Head to participate in this process; and particularly to strengthen the department's basic and clinical research programme to complement existing strengths in teaching and clinical service. Women and minorities are encouraged to apply for the Headship position. Additional faculty positions for recruitment will be made available in support of this research initiative.

Applications and nominations should be directed to:

Pathology Head Search Committee Chair
University of Arizona Health Sciences Center
College of Medicine
Administration — Searches and Reviews — Room 2206
Tucson, Arizona 85724

The review of applications will begin on October 16, 1989, and will continue until the position is filled.

Applications should include a curriculum vitae with complete address and telephone number, along with the names, addresses, and telephone numbers of at least three references.

THE UNIVERSITY OF ARIZONA IS AN EQUAL EMPLOYMENT OPPORTUNITY/AFFIRMATIVE ACTION EMPLOYER

(NW4272)A

The University of Virginia
Thaler Center for AIDS Related Research

ENDOWED PROFESSORSHIP IN AIDS RESEARCH

The University of Virginia Health Sciences Center is seeking an outstanding scientist to lead the newly created Thaler Center for AIDS Related Research. The candidate should have a proven record of achievements in basic AIDS research and a willingness to provide leadership for new programs. The academic appointment will be at the level of Professor in an appropriate Department within the Health Sciences Center. The University of Virginia provides an outstanding environment and support facilities for basic research including active interdisciplinary research and training programs in Immunology, Cell and Molecular Biology, Infectious Diseases, and Cancer Research. Letters of nomination or application should include a curriculum vitae as well as the names of four references and should be forwarded to: **Dr. J. Thomas Parsons, Search Committee, Thaler Center for AIDS Research, Department of Microbiology, Box 441, University of Virginia Health Sciences Center, Charlottesville, VA. 22908.**

The University of Virginia is an Equal Opportunity/Affirmative Action Employer. (NW4278)A

ASSISTANT PROFESSOR — IMMUNOLOGY

Department of Veterinary Microbiology & Immunology, School of Veterinary Medicine, University of California is seeking a highly qualified applicant to fill a tenure track position in Immunology. Qualifications include the Ph.D. degree and advanced training in cellular and/or molecular biology with demonstrated research productivity and interest in Immunology. The successful candidate will be expected to contribute to the Department's and the School's Immunology teaching commitments and to establish independent and collaborative-type research programs. Apply in writing and include CV, list of publications, and names of three references. Send to: **Dr. Jeffrey L. Stott, Chairperson Search Committee, Department of Veterinary Microbiology & Immunology, University of California, Davis, CA 95616.** Applications accepted through JANUARY 15, 1989 or until a suitable candidate is identified.

THE UNIVERSITY OF CALIFORNIA IS AN AFFIRMATIVE ACTION/EQUAL OPPORTUNITY EMPLOYER (NW4283)A

UNIVERSITY OF EDINBURGH
Department of Molecular Biology
and
UNIVERSITY OF DUNDEE
Department of Biological Sciences

Two Research Associates

In a collaborative effort between these two departments and the SCRI, Invergowrie, immunological approaches will be used to identify plant proteins likely to be involved in RNA splicing. The AFRC has provided funding for two positions at the RA1B level for a period of 12 months. One post will be based in Edinburgh and one in Dundee. The work will involve the extraction of proteins from various plants and *E.coli*, antibody purification, and basic immunological procedures. Experience in these areas is desirable but not essential. Applicants should hold a degree in a relevant subject.

Applications, including curriculum vitae and the names, addresses and telephone numbers of two referees, should be sent to: **Dr J. D. Beggs, Department of Molecular Biology, University of Edinburgh, King's Buildings, Mayfield Road, Edinburgh EH9 3JR** or **Dr J. W. S. Brown, Department of Biological Sciences, University of Dundee, Dundee DD1 4HN.**

SUNY STONY BROOK

DEPARTMENT OF MICROBIOLOGY

POSTDOCTORAL POSITION

is available for the study of SV40 T antigen function in viral replication and in oncogenesis. A background in biochemistry, genetics, or molecular biology is preferred.

Send resume and three references to: Dr. Peter Tegtmeyer, Department of Microbiology, SUNY Stony Brook, Stony Brook, NY 11794-8621.

SUNY Stony Brook is an Affirmative Action/Equal Opportunity Eductor and Employer. (NW4243)A

POSTDOCTORAL POSITION

currently available, to investigate the structure, function and regulation of eukaryotic ribosomes. Salary negotiable Experience in protein chemistry, molecular biology. Send CV and references to: **Dr. Robert R. Traut, Dept. of Biological Chemistry, University of California, Davis, CA 95616. (916)752-3354.** The University is an equal opportunities employer (NW4284)A

UNIVERSITY OF SOUTHAMPTON

Lectureship in Biochemistry

Applications are invited for the above position which will be available from 1 January because of the award of a Lister Institute Fellowship to Dr B A Connolly. Applicants should possess a PhD and have postdoctoral experience and preference will be given to candidates with interests in the molecular aspects of nucleic acids or proteins. The position will be for a period of five years on the Lecturer Grade A salary scale: £10,458–£15,327 per annum Starting salary dependent on age and experience.

Candidates should send 5 copies of applications including CV and the names and address of three referees to **Ms J A Doyle, Staffing Department, University of Southampton, Highfield, Southampton, SO9 5NH,** from whom further particulars may be obtained. Please quote Ref. No 46/JAD/jm Closing date. 20 October 1989 (1539)A

FACULTY POSITION in EXPERIMENTAL PHYSICAL CHEMISTRY

The Department of Chemistry at Washington University in St. Louis invites applications for a tenure-track position, effective September, 1990. Primary consideration will be given to applicants at the Assistant Professor level, but candidates with distinguished records will be considered for higher-level appointments. Candidates should submit, by November 1, 1989, a curriculum vitae and a description of proposed research, and arrange to have three letters of reference sent to: **Professor Dewey Holten, Chairman, Physical Chemistry Search Committee, Department of Chemistry, Washington University, St. Louis, MO 63130.** Washington University is an Affirmative-Action, Equal Opportunity Employer, and employment eligibility verification will be required of the successful candidate. (NW4169)A

POST DOCTORAL RESEARCH ASSOCIATES

Two positions are available to work on the genetics and molecular regulation of Mg^{2+} transport systems in bacteria, yeast, and mammalian cells and on relationship of Mg^{2+} transport systems to those for other ions, especially Ca^{2+} Experience in molecular cloning, PCR and/or bacterial genetics preferred. Available 1/1/90.

Please contact: **Dr Michael E. Maguire, Department of Pharmacology, School of Medicine, Case Western Reserve University, Cleveland, OH 44106** *Equal Opportunity/Aff Action Employer.* (NW4252)A

Southampton University High Energy Astrophysics Group

DETECTOR PHYSICIST

A vacancy currently exists for a **Post-Doctoral Research Assistant/Experimental Officer** who will be responsible for the development of position sensitive γ-ray detectors for future space-borne imaging telescopes. The current research programme centres around the development of CsI(T?)/Photodiode combinations and the application of new position sensitive photomultipliers which can provide millimetric pixels. Experience in this general area would be an advantage

The appointment will involve short periods of work within the laboratories of our European partners

The appointment will be made for an initial period of 3 years, but may be extended thereafter. Salary will be on the Research 1A Scale up to £13,527

Applications, together with the names of two referees should be sent to **Dr. A. J. Dean, Department of Physics, The University, Highfield, Southampton,** to arrive by 9th October, 1989 Please quote reference number 68/JAD/nvs. (1631)A

PUBLIC HEALTH LABORATORY SERVICE

NATIONAL COLLECTION OF TYPE CULTURES

PRINCIPAL GRADE MICROBIOLOGIST LEADER PLASMID SECTION

Salary: £15,937-£21,746 (incl London Weighting).

A responsible position is vacant to lead the NCTC Plasmid Section. The Section provides a supply service of authenticated plasmids and transposable elements, at present mainly enterobacterial and pseudomonad, and carries out fundamental research into the occurrence and molecular structure of plasmids. Duties include extension of the collection, management of the Section staff, and to originate and lead appropriate research Experience in the field essential

Application form and job description available from. Personnel Department, Public Health Laboratory Services, Board Headquarters, 61 Colindale Avenue, London NW9 5HT.

ROWETT RESEARCH INSTITUTE
Bucksburn, Aberdeen, AB2 9SB

IMMUNOLOGIST HSO/SSO GRADE

An immunologist is required to expand a research programme on the effects of diet and early nutrition on the immunological development of the young animal using a pig model New *in vitro* technology is required to investigate the role of micronutrient in antigen processing, cell cooperation and effector cell functions with emphasis on molecular biology and control of lymphoid cell membrane glycoconjugate receptor expression in the gut

A proven research record in cellular immunology with experience in immunoassays, cell culture, monoclonal antibody production, cytochemistry and other relevant aspects of cell biology is essential.

This is a permanent position but the appointment will be for three years in the first instance at either Higher Scientific Officer or Senior Scientific Officer level with salary grade and salary depending upon qualifications and relevant experience based on the following minimum requirements

First or upper second class honours degree in an appropriate discipline with at least 2 years postgraduate experience for HSO and 4 years for SSO appointment.

Salary Range: HSO £10,678 to £14,909; SSO £13,254 to £18,864.

The Institute is an equal opportunities employer and a non-contributory superannuation scheme is in operation.

The Rowett Research Institute is Western Europe's leading centre for studies in nutritional science. It is located on the outskirts of Aberdeen and has close links with the other prominent educational and research centres in Grampian Region which is one of Scotland's most thriving and attractive areas

Applications in writing with a full CV and the names and addresses of 2 referees should be sent to the Personnel Officer at the Institute from whom further details can be obtained. Closing date: 12th October 1989.

THE ALL AFRICA LEPROSY AND REHABILITATION TRAINING CENTRE (ALERT) — HAS THE FOLLOWING VACANCY:

SURGEON

REQUIREMENTS

1. Should be an orthopaedic or plastic surgeon, preferably with an experience and penetrating knowledge in leprosy surgery.
2. Advantageous to have experience in teaching.
3. Should have training or experience in management.
4. Should have work experience of a minimum of five years, preferably with an overseas experience.
5. Should have good leadership qualities
6. Should have good command of English language.
7. Should be innovative and be able to adapt or modify existing situations.
8. Date of employment; as soon as possible
9. Salary negotiable
10. Contract period of two years

Address application with copies of testimonials and Job certificates in English to the: Executive Director, ALERT, P.O. Box 165, Addis Ababa, Ethiopia.

The deadline for submitting application is 45 days after the publication of this vacancy. (W6506)A

CHAIR

Department of Biological Sciences University of Pittsburgh

Applications and nominations are invited for the position of Chairperson of the Department of Biological Sciences at the University of Pittsburgh. Candidates should have a distinguished research program as well as the energy and ability to lead the Department into its next phase of development. Currently there are 30 tenure-stream faculty members Additional appointments have been approved. Within the department, or available to its members, are facilities for DNA synthesis and sequencing, protein sequencing and peptide synthesis, cell culture and virology, hybridoma production, large scale fermentation, electron microscopy and macromolecular x-ray crystallography. The department trains 60 graduate students in addition to 350 undergraduate majors. Candidates from all areas of modern biological research are welcome. Review of applications will begin October 1, 1989. Applicants should send a curriculum vitae, along with the names of potential referees to:

Mary Edmonds, Chair Search Committee, Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260.

The University of Pittsburgh is an EEO/AA employer.

FACULTY POSITION, MICROBIAL PATHOGENESIS

Applications are invited for a tenure track appointment at the assistant or associate professor level in the Department of Microbiology and Immunology, UCLA School of Medicine. Applicants should have a Ph.D. (or equivalent degree) and research interest in the pathogenesis of microbial diseases caused by bacteria or fungi. The candidate selected will participate in a program in molecular pathogenesis currently supported by an NIH training grant, in addition to teaching medical and graduate students. Salary and benefits will be commensurate with the candidate's qualifications.

Applications should be submitted by 1 November 1989 and should be comprised of a letter of application, a complete curriculum vitae, copies of two recent publications, and names and addresses of three references. The complete application package should be submitted to: **Dr. Dexter H. Howard, Chairman of the Microbiology Search Committee, Department of Microbiology and Immunology, UCLA School of Medicine, Los Angeles, CA 90024–1747.**

UCLA is an Affirmative Action and Equal Opportunity Employer.

(NW3985)A

STATE UNIVERSITY OF NEW YORK AT BUFFALO

The Department of Geology invites nomiations and applications for the position of Chairman of the Department and Professor (with tenure). Salary will be highly competitive We seek applicants with excellent research accomplishments and the interest and administrative ability to provide academic leadership for a research-oriented department.

Applicants should send a curriculum vitae, brief statement of research/teaching interests, and names of four references to:

Dr. Lewis A. Coburn
Search Committee Chairman
c/o Department of Geology
SUNY/Buffalo
4240 Ridge Lea Campus
Buffalo, New York 14260

The deadline for applications is December 1, 1989. Later applications will be considered until the position is filled.

SUNY/Buffalo is an Equal Opportunity/Affirmative Action Employer. We are interested in identifying prospective minority and women candidates. No person, in whatever relationship with the State University of New York at Buffalo, shall be subject to discrimination on the basis of age, creed, color, handicap, national origin, race, religion, sex, marital or veteran status (NW4281)A

The Department of Biology at Memphis State University

invites applications for two tenure track positions, one in **biochemistry** and the other in **molecular biology.** Appointments will be made at the rank of Assistant Professor/Associate Professor depending on qualifications Minimum qualifications are a Ph D degree and postdoctoral training Applicants for the biochemistry position are expected to have an academic and research concentration in an area of biochemistry with support training in chemistry and biology Applicants for the molecular biology position are expected to have an academic and research concentration in an area of molecular biology with support training in genetics, cell biology or biophysics Successful candidates will be expected to develop a strong graduate research program and to provide quality teaching to undergraduate and graduate students Review of applicants will begin on Oct. 1, 1989 and continue until the positions are filled. Interested candidates should send curriculum vitae, statement of research plans, representative reprints and names of three references to

Dr. S. Edward Stevens, Jr., Chair of Search Committee, Department of Biology, Memphis State University, 201 Life Sciences Building, Memphis, TN 38152.

Successful candidates must meet Immigration Reform Act criteria

Memphis State University is an Equal Opportunity/Affirmative Action Employer

(NW4279)A

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
MOLECULAR BIOLOGIST

Applications are invited for two positions in the Department of Medical Microbiology to work on the molecular biology of *Mycobacterium tuberculosis* antigenes. The successful candidates will join an existing group which has cloned and sequenced a major *M tuberculosis* antigen that is homologous to heat shock proteins. Baird P N, Hall L, Coates A R M. J gen Microbiol (1989), **135**, 931; Baird P N, Hall L, Coates A R M Nucl Acids Res (1988), **16**, 9047, Cookson M J, Baird P N, Hall L, Coates A R M Nucl Acids Res (1989), **17**, 6392; Coates A R M, Baird P, Hall L, Proceedings of Stress Proteins and Inflammation, London (1989) Richlieu Press (in press).

The project which is funded through the division of Research Grants, National Institutes of Health, USA, will focus on the expression of these proteins by recombinant DNA methods and the testing of the products in animal models. A short period of time will be spent in the molecular biology laboratory in the USA by the successful candidte to learn new technology. Experience in molecular biology techniques and animal work is desirable, but not essential

Post-doctoral applicants are encouraged to apply, but a PhD is not essential, and those wishing to take a higher degree such as M Phil or PhD are also encouraged to apply.

Salaries are in the region of £12,000 pa plus London weighting. Curriculum vitae and the names and addresses of two referees should be sent to **Dr A R M Coates, Department of Medical Microbiology, The London Hospital Medical College, Turner Street, London E1 2AD, tel no. 01-377 7643.**

Australia

LECTURER
(LIMITED TENURE)
IN
PLANT ECOLOGY
SCHOOL OF BOTANY

The School of Botany invites applications to fill a position in plant ecology to both broaden the existing ecological bass and be part of the School's current research groups. Research on plant communities, particularly eucalypt communities, and ecosystems is currently an important facet of the School.

Applicants with expertise in physiological ecology, community dynamics or biogeochemical cycling are invited to apply. Preference will be given to a strong field experimentalist with a knowledge of Australian vegetation.

The appointee will be expected to teach in undergraduate courses in plant biology and ecology.

For futher information on the position contact Dr Pauline Ladiges (61 3) 344 7156.

The appointee should be available to take up the position from 1 January 1990. The position is available for 3 years in the first instance.

Salary will be in the range: $A30,737-$A40,100 per annum.

Closing Date: 13 October 1989.

Position Number: L6060110.

Further printed information regarding details of application procedures and conditions of appointment is available from Mary Petras, Personnel Services on (61 3) 344 7546.

Applications, in duplicate, including names and addresses of at least three referees and quoting the relevant position number should be addressed to The Director, Personnel Services, The University of Melbourne, Parkville, Victoria, 3052, Australia.

An equal opportunity employer. (W6501)A

RESEARCH FELLOWS (GRADE 1/2) (SEVERAL POSITIONS) ARE AVAILABLE IN THE DEPARTMENT OF PRECLINICAL VETERINARY SCIENCES FOR

MOLECULAR BIOLOGISTS/ IMMUNOLOGISTS PROTEIN CHEMISTS/ IMMUNOCHEMISTS MOLECULAR GENETICISTS

The new positions have been made available as part of a major expansion into Animal Biotechnology in the School of Veterinary Science. The existing research groups forming the basis of the Animal Biotechnology research team are foremost in reminant immunology and molecular biology and are actively engaged in the development of parasite vaccines and experimental approaches for the production of transgenic animals.

The positions are available in research groups working in the following areas:

1. Molecular cloning and functional characterisation of sheep interleukins (Drs. A. Nash and E. Meeusen).
2. Biochemical characterisation and purification of parasite antigens (Drs. E. Meeusen and J. Walker).
3. Immune responses to endo and ecto-parasites (Drs. V. Bowl and J. Walker).
4. Molecular cloning and characterisation of parasite antige (Drs. J. Walker and T Adams
5. Gene mapping and disea resistance in sheep (Drs. Adams and K. Gogoli Ewens).

For further information conta Dr. Mal Brandon 344 7345 or t respective scientists 344 7344 f (1), (2), (3) and (4) and 344 73 for (5).

Although the nature of t grants requires that the positio be renewed yearly, the grants ha been awarded for between 3 and years with superannuation ben fits available.

Salary is in the range: A$27,13 A$30,882 (Research Fello Grade 1)
A$31,259-A$40,622 (Resear Fellow Grade 2)

Closing Date: 20 October 198

Position Number: 260A041.

Written applications shou reach the Director, Personnel Se vices as stated below.

Applications, in duplicate, i cluding names and addresses of least three referees and quotir the relevant position numb should be addressed to The Dire tor, Personnel Services, The Un versity of Melbourne, Parkvill Victoria, 3052, Australia.

An equal opportunity employer. (W6500)A

HUMAN FRONTIER SCIENCE PROGRAM (HFSP)

The new international program starts now.

The Human Frontier Science Program (HFSP) is an international program*, which was proposed by the Japanese Government at the Venice Economic Summit Meeting in 1987, and which has been discussed at the Toronto Economic Summit Meeting and at the meetings of eminent scientists and experts from the Economic Summit member countries and the Commission of the European Communities. The HFSP aims at promoting, through international cooperation, basic research focused on the elucidation of the sophisticated and complex mechanisms of living organisms. To the fullest possible extent the research results will be used for the benefit of all mankind. The HFSP is also intended to encourage international interdisciplinary research by researchers early in their careers who are expected to play an important role in originating and pursuing creative research.

* For more detailed information refer to Nature, vol. 340, 6238, September 14th 1989 classified pages.

Invitation for Applications

Research Grants/Fellowships/Workshops

Research Areas of the HFSP:

(A) Basic research for the elucidation of brain functions
1. Perception and Cognition
2. Movement and Behaviour
3. Memory and Learning
4. Language and Thinking

(B) Basic research for the elucidation of biological functions through molecular level approaches
1. Expression of Genetic Information
2. Morphogenesis
3. Molecular Recognition and Responses
4. Energy Conversion

Research grants: Grants for basic research carried out by international joint research teams represented by principal researchers from one of the eligible countries*.

Fellowships: Fellowships for researchers from the eligible countries who wish to do research in foreign countries, or for researchers outside the eligible countries who wish to do research in one of the eligible countries. Each fellowship is worth up to approximately U$50,000.

Workshops: Subsidies for international workshops organized by researchers from the eligible countries. Each Workshop is worth up to approximately U$100,000.

* The eligible countries for fiscal year 1989 are Canada, France, F.R.G., Italy, Japan, U.K., and U.S.A.. Researchers in non-summit EC member countries may apply through the Commission of the EC on equal terms with the researchers in the eligible countries. (Details in the guidebook)

Prospective number of awards and duration of each activity for fiscal year 1989:

Research Grants	~	20	3 years
Long-term Fellowships	~	100	3 months – 2 years
Short-term Fellowships	~	50	2 weeks – 3 months
Workshops	~	10	----

Application Deadline: November 15, 1989
In fiscal year 1989, awardees will be determined by March 31, 1990, after the review procedures are completed by the organization to implement the HFSP.

Further information:
Until the organization is established in Strasbourg (France) this fall, the Task Force on the HFSP of the Japanese Government will undertake preparatory activities on behalf of the organization.

Guidebooks and Application Forms may be obtained upon request from the address given below. (Please indicate which program activity [Research Grant/Fellowship/Workshop] you are interested in.) (W6443)G

HFSP

UNIVERSITY OF OXFORD

DEPARTMENT OF ZOOLOGY
DEPARTMENTAL DEMONSTRATOR IN ZOOLOGY (Ecology)

Applications are invited for the above post The person appointed will be expected to take up the post in January 1990. The successful candidate should have a PhD degree by the time the post is taken up The duties of the post involve the teaching to undergraduates, more particularly practical and field classes; the post holder will be expected to undertake research in an area of ecology for which modest departmental support and facilities will be available; involvement in the supervision of graduate research students encouraged

The appointment will be for three years in the first instance with the possibility of renewal for up to a maximum of a further three years The salary will be within University scale £9,816 per annum to £12,879 per annum with membership of USS.

Applications (giving full curriculum vitae and the names of two referees) should be sent to the **Head of Department, Department of Zoology, South Parks Road, Oxford OX1 3PS before 7 October 1989.** (1634)A

The University is an Equal Opportunity Employer

UNIVERSITY OF READING

LECTURESHIP IN MICROBIOLOGY

Applications are invited for a Lectureship in the Department of Microbiology, School of Animal and Microbial Sciences. The preferred areas are Bacteriology and the Molecular Immunology of Infectious Diseases but applications from candidates with interests in other areas of microbiology will be considered. The appointee will be expected to initiate independent research programmes through obtaining external funding and to contribute to the teaching and administrative commitments of the Department and the School

The Microbiology Department will shortly move into new purpose built laboratories which will have generous space and excellent facilities for research Salary Scale £10,458 to £15,373 per annum (Grade A) plus USS benefits. Further particulars and application forms (2 copies) are available from Personnel Office, University of Reading Whiteknights, PO Box 217, Reading RG6 2AH, Telephone 0734-318751. Candidates from overseas need only send a cv and the names of two academic referees More information about this attractive post may be obtained from Professor J W Almond, Department of Microbiology, telephone 0734-318901 Please quote reference AC8915R Closing date 27 October, 1989.

(1607)A

PHLS CENTRE FOR APPLIED MICROBIOLOGY AND RESEARCH

DIVISION OF BIOTECHNOLOGY

MICROBIOLOGICAL DEGRADATION OF ORGANOCHLORINE XENOBIOTICS

A Microbiologist is required to join a group of scientists studying the microbial degradation of chlorinated organic pollutants.

The successful applicant will probably have a degree or Ph.D. in microbiology, biochemistry or an environmental discipline The post is funded by the Department of the Environment and the appointment will be initially until 31st January 1991

The appointment will be on the scale from £7,378-£15,394 (under review), depending on qualifications and experience.

NHS terms and conditions will apply Candidates wishing to informally discuss the post should contact Dr A Maule, telephone Idmiston (0980) 610391, ext 2395

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology & Research, Porton Down, Salisbury, Wiltshire SP4 0JG, telephone Idmiston (0980) 610391 ext 240, to whom completed forms should be returned by 6th October 1989, quoting Post No 2016.

(1611)A

THE UNIVERSITY OF ADELAIDE

SOUTH AUSTRALIA

invites applications from both women and men for the following position.

RESEARCH ASSOCIATE/ POSTDOCTORAL FELLOW IN MOLECULAR PLANT-MICROBE INTERACTIONS

(ref: 6887) in the Department of Plant Pathology at the Waite Agricultural Research Institute which is centrally located in the city of Adelaide.

The project involves a molecular study of genes involved in the enhancement of the Rhizobium-legume nitrogen fixation symbiosis. The successful applicant will participate in ongoing research to investigate the transcriptional and translational regulatory mechanisms involved in the symbiotic control of these genes.

Applicants should have a PhD or equivalent. Experience in Molecular Biology is essential and preference will be given to those candidates with expertise in both Molecular Genetics and DNA Manipulation.

The position is available immediately for three years from the date of commencement.

Further information concerning the project and duties of the position may be obtained from Dr Peter Murphy, Department of Plant Pathology, telephone (08) 372 2262, Facsimile: 618 338 1757.

Information about the general conditions of appointment and selection criteria may be obtained from the Senior Assistant Registrar (Personnel) at the University.

Salary per annum: AUS$27,139 × 5 – AUS$30,882

Applications, in duplicate, quoting reference number 6887 and giving full personal particulars (including whether candidates hold Australian permanant residency status), details of academic qualifications and names and addresses of three referees should reach the Senior Assistant Registrar (Personnel) at the University of Adelaide, GPO Box 498, Adelaide, South Australia, 5001, Telex UNIVAD AA 89141, Facsimile 618 224 0464 not later than 10 November 1989.

The University reserves the right to make enquiries of any person regarding any candidate's suitability for appointment, not to make an appointment or to appoint by invitation.

The University of Adelaide is an Equal Opportunity Employer.

(W6504)A

University of Saskatchewan
Department of Biology

POSTDOCTORAL POSITION

Applications are invited for a postdoctoral position in insect reproductive physiology. Candidates should have expertise in modern biomedical techniques, and some knowledge of insect tissue culture would be advantageous The successful applicant will participate in an ongoing study of the regulation and functions of reproductive activity in the male insect. Salary will be in accord with NSERC Canada guidelines (current range can $21,500–23,000 per annum) Please send *curriculum vitae* and names/addresses of three referees to:

Prof. C. Gillott,
Department of Biology,
University of Saskatchewan,
Saskatoon, SK S7N 0W0
Canada

For further information, phone (306) 966-4401. (NW4268)A

Postdoctoral Position

MEMBRANES

Persons to participate in specific projects either at the molecular or at the cellular level. Areas of interest include membrane fusion, multidrug resistance and lipid regulation of enzyme activities. Highly qualified individuals please send full curriculum vitae and names of two references to: **Dr. R.M. Epand, Dept. of Biochemistry, McMaster University Health Sciences Centre, 1200 Main Street West, Hamilton, Ontario, Canada, L8N 3Z5.**

(NW4266)A

MOLECULAR VIROLOGIST

to study the regulation of gene expression of HIV-1. Must have a Ph.D. and 4 to 6 years of productive post doctoral experience. Expertise is essential in HIV regulatory proteins (Nef, Rev and tat), cDNA cloning, mutagenesis, DNA sequencing, gene expression, RNA mapping and viral biology. Send resume to **Dr. B. Baroudy, Director, Division of Molecular Virology, James N. Gamble Institute of Medical Research, 2141 Auburn Avenue, Cincinnati, Ohio 45219.** *Affirmative Action/ Equal Opportunity Employer*

(NW4262)A

the widest international selection of jobs in science — EVERY WEEK

Faculty Position in Plant Population Biology at the University of California, Berkeley

The Department of Integrative Biology, pending final budgetary approval, invites applications for a tenure-track Assistant Professor position, beginning with the 1990-91 academic year. The research interests of the candidate should be in experimental plant population biology. Applicants should send a curriculum vitae, statement of research and teaching, objectives, relevant reprints and manuscripts, and names and addresses of three references to:

Chair, Plant Population Biologist Search Committee, Department of Integrative Biology, University of California, Berkeley, CA 94720.

Closing date for receipt of applications: January 15, 1990.

The University of California is an Equal Oppportunity, Affirmative Action Employer. (NW4277)A

National Institutes of Health

POSTDOCTORAL POSITION

A postdoctoral position is available immediately for in-vitro study of receptor and post receptor mechanisms involved in the pathogenesis of HIV induced dementia. The applicants should be legal U.S. residents and should have obtained a Ph.D. degree within the last three years. Background in protein chemistry and/or receptor biochemistry or second messenger pathways is desirable. Work with infectious HIV will not be involved. Reply with curriculum vitae and three references to:

Drs. George Kunos or Laszlo Takacs
Laboratory of Physiologic and Pharmacologic Studies
National Institute on Alcohol Abuse and Alcoholism
National Institutes of Health
12501 Washington Avenue
Rockville, MD 20852.

NIH is an equal opportunity employer. (NW4263)A

POINTMENTS continued on page 24

ROWETT RESEARCH INSTITUTE
Bucksburn, Aberdeen, AB2 9SB
BIOCHEMIST/PHYSIOLOGIST
BIOCHEMIST/MOLECULAR ENDOCRINOLOGIST
(2 Posts at HSO/SSO Grade)

The Rowett Research Institute is Western Europe's leading centre for studies in nutritional science It is located on the outskirts of Aberdeen and has close links with the other prominent educational and research centres in Grampian Region which is one of Scotland's most thriving and attractive areas.

POST 1 Biochemist/Physiologist

An innovative scientist is required to investigate the controls and dynamics of methyl group and S-amino acid metabolism He/she will be expected to define how the interaction between transmethylation and methionine kinetics effects both protein anabolism and the metabolism of key molecules, such as phosphatidylcholine and the purines. Primarily the studies will be directed towards ruminants and will involve extensive use of radio- and stable-isotope techniques Expertise in enzymology will also be useful. The appointee will conduct independent research within an active group directed towards understanding the metabolic constraints on growth and lactation but will be expected to interact with other researchers studying intermediary metabolism.

POST 2 Biochemist/Molecular Endocrinologist

An innovative scientist is required to investigate factors which modulate hormone or growth factor action. Experience in the chemistry of receptors and/or peptide factors would be an advantage Ultimately the research is directed towards ruminants but may involve laboratory species or cell culture at appropriate stages. The appointee will conduct independent research within an active group investigating ruminant metabolism but will be expected to interact with other researchers studying the molecular events of growth regulation.

The above 2 posts are established positions on the Institute's staff but the initial appointments will be for 3 years in the first instance at either Higher Scientific Officer of Senior Scientific Officer level with the grade and salary depending upon relevant qualifications and experience based on the following minimum requirements

First or upper second class honours degree in an appropriate discipline with at least 2 years post graduate experience for HSO and 4 years for SSO appointment.

Salary Range. HSO £10,678 to £14,909; SSO £13,254 to £18,864.

The Institute is an equal opportunities employer and a non-contributory superannuation scheme is in operation.

Applications in writing with a full CV and the names and addresses of 2 referees should be sent to the **Personnel Officer** at the Institute from whom further details can be obtained. Informal enquiries are encouraged and should be directed to Dr. G. E. Lobley on Tel. No. 0224-712751 Ext. 150.

Closing Date: October 12th (1630)A

INTERNATIONAL WEEKLY JOURNAL OF SCIENCE

STUDENTSHIPS

UNIVERSITY OF SALFORD
Department of Chemistry and Applied Chemistry
UNIVERSITY OF SOUTHAMPTON
Department of Chemistry

TWO POSTDOCTORAL RESEARCH ASSISTANTS
ONE RESEARCH STUDENTSHIP

'AMPHITROPIC LIQUID CRYSTALS'

Required to undertake research in an exciting new area of liquid crystal science on a joint project under the direction of Professor G J T Tiddy (Salford) and Dr G S Attard (Southampton). The project is funded by SERC under its Materials for the 21st Century initiative and is concerned with the synthesis and characterisation of novel amphitropic liquid crystals. One post, based at Southampton, will involve the synthesis of the liquid crystals; the person appointed to the other post based at Salford, will be responsible for the characterisation of the phase behaviour of the new materials synthesised at Southampton. A research studentship is also available for study of Langmuir Blodgett films of these materials, involving some synthesis.

Appointments will be made for one year initially, from 1 January 1990 with the possibility of renewal for up to three years. Commencing salary up to £11088 a year; USS benefits. The University is an Equal Opportunity Employer.

Letters of application, including a curriculum vitae and the names and addresses of two referees should be submitted to the **Registrar, University of Salford, Salford M5 4WT** by 13 October 1989 quoting reference CH/317/N. Informal enquiries may be made to Professor Tiddy (tel 061-736 5843 ext 641) or Dr Attard (tel 0703-595000).

(1638)F

APPOINTMENTS

DEPARTMENT OF GENETICS
HARVARD MEDICAL SCHOOL

The Department of Genetics invites applicants for the position of Assistant/Associate Professor. While qualifications for the position include a strong potential for imaginative research in contemporary genetics, we especially hope to consider individuals whose scholarship is broadly relevant to human biology. Individuals with M.D /Ph.D. degrees who are interested in being part of a basic science department, without required clinical responsibilities, are encouraged to apply. The successful candidate will be nominated for an appointment with The Howard Hughes Medical Institute Genetics Unit located within the department.

The position offers very significant scholarly and scientific resources as well as the opportunity to teach medical students and fellows with strong interests in genetics research

Applicants should submit, as soon as possible, but prior to December 31, 1989, curriculum vitae, bibliography, a brief (no more than 500 words) description of research interests and the names of three references to:

Dr. Philip Leder, Chairman
Department of Genetics
Harvard Medical School
25 Shattuck Street
Boston, Massachusetts 02115

Harvard University is an Equal Opportunity/ Affirmative Action Employer and encourages the application of qualified women and minorities. (NW4251)A

FELLOWSHIPS

The Lamont-Doherty Geological Observatory of Columbia University

POSTDOCTORAL FELLOWSHIPS in the EARTH AND OCEAN SCIENCES

The Lamont-Doherty Geological Observatory of Columbia University invites recent Ph.D. recipients or candidates for their degrees in 1988 in any field of the Earth and Ocean Sciences to apply for Postdoctoral Fellowships awarded for a period of one year (extendable to two years, in special instances) beginning in September 1990 with an annual stipend of $30,500.

The deadline for completed applications is January 15, 1990. Application forms may be obtained by writing to the **Office of the Director, Lamont-Doherty Geological Observatory, Palisades, New York 10964.** Award announcements will be made on or about February 28, 1990.

Columbia University is an Affirmative Action/Equal Opportunity Employer. (NW4211)E

FRIEDRICH MIESCHER-INSTITUT
BASEL, SWITZERLAND

POSTDOCTORAL FELLOWSHIP

Applicants with a recent Ph.D are invited for an internally funded fellowship of up to 3 years maximum duration to join an established team working on the role of DNA methylation in eucaryotic gene regulation and on the interaction of tissue-specific transacting factors (*in vivo* and *in vitro*) with regulatory elements of genes.

The possible role of covalent modifications of transacting factors will also be studied. We are working on genes that control differentiation and genes controlled by hormones The Institute provides outstanding facilities in a purely research environment.

Position is available in spring 1990. Candidates should have a good background in biochemistry, molecular biology and biology.

Applications (with CV) should be sent to: **Dr. Jean-Pierre Jost, Friedrich Miescher-Institut, P.O. Box 2543, CH 4002 Basel, Switzerland.** (W6465)E

DYSTONIA MEDICAL RESEARCH FOUNDATION

Invites Research Grant and Fellowship Applications

Dystonia is a symptom which occurs in several human disorders. It consists of involuntary, often prolonged muscle spasms resulting in abnormal postures. The diseases include dystonia musculorum deformans (torsion dystonia), spasmodic torticoills, writers' cramp, blepharospasm and orofacial dystonia Dystonia is thought to be due to basal ganglia dysfunction but pathological findings are few. Present animal models are unsatisfactory.

Research proposals on dystonia are solicited, particularly those aimed at discovering the cause or improving the treatment. Grants are typically limited to $25,000 per year, renewable for one or two additional years.

Applications are sought for a $50,000 a year Fellowship, renewable for three years The objective is to attract gifted investigators to commiting their time and effort to research in dystonia, not only for the period of the Fellowship Award, but hopefully for many years thereafter Applicants must have an M.D. or Ph D. degree and strong support from sponsoring institution.

Deadline for Grant and Fellowship review is December 15, 1989. For application forms (please specify Grant or Fellowship) please write to.

Charles H. Markham, M.D.,
Scientific Director,
Dystonia Medical Research Foundation,
8283 Wilshire Boulevard, Suite 88A,
Beverly Hills, California 90211.

(NW4271)E

The Division of Medical Genetics
Emory University School of Medicine

POSTDOCTORAL FELLOWSHIP

The Division of Medical Genetics, Emory University School of Medicine, is seeking application for a postdoctoral fellowship to study the molecular biology of Galactosemia To apply, send curriculum vitae and a synopsis of current and future research interest to:

Dr. Louis J. Elsas, II, Director
Division of Medical Genetics
Emory University School of Medicine
2040 Ridgewood Drive
Atlanta, GA 30322

Deadline for receipt of application is October 31, 1989.
Emory University School of Medicine is an Equal Opportunity/ Affirmative Action Employer. (NW4256)E

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF PHYSIOLOGY AND PHARMACOLOGY

POSTDOCTORAL FELLOWSHIP

Applications are invited for a Wellcome Trust Postdoctoral Fellowship to investigate the regional haemodynamic effects of central neuropeptides in hypertension The position is available for two years in the first instance, and would be best suited to a person with experience of the appropriate techniques.

Applicants should send their curriculum vitae and the names and addresses of 2 referees to **Dr S M Gardiner, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, Tel: 0602 709476.** Closing date 31st October 1989. (1613)E

— FELLOWSHIPS continued on pages 28 & 29

AWARDS

CHEMISTRY today
CHIMICA oggi

TEKNOSCIENZE Srl, publisher of the journal **CHIMICAoggi,** is offering Italian and Foreign researchers

4 PRIZES

valued at Lit. 2 000.000 each to be awarded for scientific manuscripts that cover the following areas:

Chemistry ● Analytical Chemistry Pharmaceutical Chemistry ● Biotechnology

The research topics relating to the above mentioned fields are:

Organic Chemistry
— Asymmetric synthesis
— Carbohydrate chemistry
— Isolation, structural determination and/or natural product synthesis
— The study of reaction mechanisms
— Application of organometallic chemistry to the development of modern catalysis

Analytical Chemistry
— The development of an analytical method to determine a given species or to solve an analytical problem of relevant interest
— The design and production of equipment or of an instrumental analytical component that improves sensitivity, accuracy and speed compared to present-day processes
— The development of an analytical method of particular environmental interest

Biotechnology
— Human genetics. Prenatal screening (new methods)
— Monitoring of environmental contaminants and/or biological techniques for environmental protection
— Plant biotechnology

Pharmaceutical chemistry
— Drug design – basic molecular modeling
— Drug design for the development of active molecules in the cardio/vascular sector.
— The study of molecules involved in the interaction with H receptors.
— The study of therapeutic applications of biotechnological proteins
— Thermodynamics in irreversible processes in biology

To participate, candidates must. 1) be 35 years of age or younger; 2) hold a degree in Chemistry, Biology, Chemistry and Pharmaceutical Technology or Pharmacy, 3) submit manuscripts no later than 30/11/89.

The papers, which must be submitted in English, will be judged by a Scientific Committee whose evaluation is irrevocable.

For further information, please contact: **Ms. Yvonne Pomposo**
TEKNOSCIENZE Srl – Via Vincenzo Gioberti 1 – 20123 Milano (Italy)
Tel (02) 4818118–4818011 – Fax (02) 4818070

The Regulation of Growth and Development — The Elucidation of Signal Pathways 14th and 15th December 1989

At the Edward Lewis Lecture Theatre, University College and Middlesex School of Medicine, London. Organisers: Mike Waterfield, Jeremy Brockes and Peter Parker (Lugwig Institute for Cancer Research)

Fee: £50, Coffee and Tea included.

Contact: **Mrs B. Cavilla, Institute of Biology, 20 Queensberry Place, London SW7 2DZ** Tel 01-581 8333 for programme and forms. (1621)M

SCIENCE AND MEDICINE CONFERENCE

To be held at the Royal College of Physicians on 1st and 2nd November 1989

The conference will include sessions on:

NMR in biology and medicine
Overview—Prof G Radda FRS
NMR investigations of cardiac metabolism
The use of ^{31}P and ^{1}H NMR spectroscopy in the investigation of animal models of disease
Combined use of MR-imaging with MR-spectroscopy

Metabolic basis of disease
Overview—Prof K.G M.M. Alberti
The biochemical and molecular biological basis of chronic granulomatous disease
Hereditary intolerance of fructose: new approaches to recognition and diagnosis

Neo-pharmacology
Overview—Prof A.M. Breckenridge
Molecular mechanisms of drug toxicity
Monoclonal antibodies for immuno-suppression and tolerance
The phosphoinositide signalling pathway in the CNS

Applications of genetics
Overview—Prof M. Bobrow
Genetic fingerprinting—the science and its application
Sex, disease and evolution

Transgenesis
Overview—Prof S. Brenner FRS
Embryo and other cells in new genetics
Foreign genes as cellular markers in embryogenesis
Tracing early cell change in mouse embryo
Chromosomal imprinting and its relevance for development and embryonal tumours
Gene treatment
The new experimental mammalian genetics
Production of human proteins by transgenic animals
State of the art lecture—'Determining atomic structure of living matter—what use to medicine?'—M Perutz OM FRS

Croonian Lecture — 'Molecular basis of diarrhoea' — L A. Turnberg
Humphry Davy Rolleston Lecture: 'RNA editing, dietary lipid absorption and atherogenesis' — J Scott

The registration fee of £80 includes coffee, lunch and tea

Application forms are available from: The Conference Secretary, Royal College of Physicians, 11 St Andrew's Place, Regent's Park, London NW1 4LE Telephone 01-935-1174 (1599)C

Royal Postgraduate Medical School
(University of London)

Monoclonal Antibody Techniques

Specialist Short Course

20–24th November 1989

Applications are invited for this full-time one week course.

The course consists of lectures and practicals covering the following topics:

- ☆ *Immunisation*
- ☆ *Choice of Myeloma lines*
- ☆ *PEG cell fusion*
- ☆ *Electrofusion*
- ☆ *Cloning*
- ☆ *Sceening systems*
- ☆ *Antibody purification*
- ☆ *Immuno-blotting*
- ☆ *The effects of affinity/avidity in different assay systems*
- ☆ *Discussion on some of the current uses including antibody engineering and clinical applications*

FEBS WINTER SCHOOL
(Advanced Lecture Course)

Genetics, Biochemistry and Ultrastructure of MEIOSIS

Obertraun (near Hallstatt), Upper Austria
March 31-April 6, 1990

This course should provide an overview of recent knowledge of the biochemistry, genetics and ultrastructure of all aspects of meiosis. This will lead to a synthetic concept of the meiotic process.

Organizers

M. Breitenbach, J. Loidl, D. Schweizer (University of Vienna), **R. Easton Esposito** (University of Chicago)

Speakers to include

B. Byers (Seattle), **A. Carpenter** (San Diego), **M. Dresser** (Oklahoma City), **R. Easton Esposito** (Chicago), **S. Gasser** (Lausanne), **S. Hawley** (New York), **Ch. Heyting** (Wageningen), **R. Holliday** (Sydney), **Y. Kassir** (Jerusalem), **A. Mitchell** (New York), **P. Moens** (North York), **A. Nicolas** (Orsay), **S. Rasmussen** (Copenhagen), **S. Roeder** (New Haven), **J. Segall** (Toronto), **M. Simon** (Pasadena), **H. Stern** (La Jolla), **M. Yamamoto** (Tokyo), **D. Zickler** (Orsay).

Fee: 3,000 Austrian Schillings, including course-fee and full board at the Bundessportschule Obertraun. Fifteen FEBS Youth Travel Grants are available for those qualifying (under 31 years, student in a FEBS-Country and member of a FEBS Constituent Society).

Please write for application forms by November 1, 1989 to: **M. Breitenbach, Institut für Mikrobiologie und Genetik, Universität Wien, Althanstraße 14, 1090 Wien, Austria.** (W6498)C

STA FELLOWSHIPS

Postdoctoral Fellowships in Japanese Government Laboratories

The Japanese Science and Technology Agency (STA) is offering postdoctoral fellowships to scientists and engineers of the countries listed below for periods of 6 months to 2 years to be held in any Japanese national laboratory (excluding university and university-affiliated laboratories). Over one hundred Japanese research laboratories covering almost all areas of science, engineering and medicine are participating in the scheme.

The fellowships are open to young PhD holders of under 35 (although older researchers will be considered) from universities, research councils, government research laboratories and industry. Any science or engineering discipline will be considered except military R & D. Applicants will be required to supply a letter of invitation from their Japanese host institution (the organizations listed in Table 1 provide help in contacting suitable host institutions).
Those in the final stages of a PhD may also apply.

There are no closing dates but candidates are encouraged to submit their applications as soon as possible. Fellowships for fiscal 1989 must be taken up by March 1990.

FELLOWSHIP AWARDS

Fellowships include round-trip air tickets (economy class) and the following tax-free allowances:

1) Living allowance: ¥270,000 (about US$2,000) a month
2) Family allowance: ¥ 50,000 a month
3) Housing allowance: up to ¥100,000 a month
   Apartments will normally be provided to awardees. The apartment floor area is 40 m^2 for awardees unaccompanied by their family and 60 m^2 for awardees to stay with their family in other than metropolitan areas such as Tokyo. If an awardee prefers to use a larger apartment because of the family size or otherwise ¥100,000 maximum per month may be paid as housing allowance; any shortfall is to be borne by the awardee.
4) International relocation allowance: ¥200,000
5) Travel allowance: ¥100,000 a year
   (within Japan)
6) Japanese language lesson courses are to be provided free of charge to the STA Fellowship awardees and their family members in Tsukuba area. Those who live in places other than the Tsukuba area will be entitled to reimbursement of Japanese language school tuition up to a specified amount.
7) Excursions or the like will be held to help make the Fellowship awardees and their family members in Tokyo/Tsukuba areas familiarized with Japan's culture, tradition and history.

In addition, ¥1,480,000 per year will be paid to the host institute to cover research costs and insurance for researchers will be paid by JISTEC during their stay in Japan to cover medical care.

APPLICATION PROCEDURE FOR STA FELLOWSHIP

Management of the STA Fellowship, including recruitment of candidates, is entrusted to the Japan International Science and Technology Exchange Center (JISTEC).

Responsible organizations overseas which represent the governments of their respective countries are given in Table 1.

A researcher wishing to be awarded the STA Fellowship should apply to the responsible organization in his/her country. Candidates are required to contact the desired host institute and obtain a letter of acceptance before filling an application with their government. Further information regarding the STA Fellowship and host Institutes is available from the responsible organizations.

A researcher whose country is not listed in Table 1 could contact a Japanese host institute directly, which in turn may recommend the reseacher to JISTEC as a candidate for STA Fellowship.

Fig. 1 shows the process from consult/contact to receipt of award.

INSET day

AIDS

A CHALLENGE IN EDUCATION

A symposium organized by the Biomedical Sciences Division of the Institute of Biology and the Institute of Education, University of London

Wednesday 29 November in the Logan Hall, Institute of Education

We are in the midst of an AIDS epidemic. Millions of people worldwide are thought to be infected with the AIDS virus (HIV); in the UK alone one person dies from AIDS every day and the number of people known to have the virus is increasing.

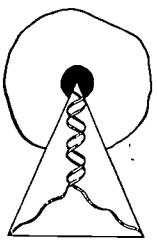
There is an urgent need for professionals and volunteers to be trained to cope with the impact of HIV infection, especially with the new demands on schools, teachers and parents. Young people are a priority group for prevention education but the message is not getting through, not to mention the problems in reaching minority groups and those with learning difficulties. But the problem does not end with children: drug addicts, prostitutes and their clients too, present special challenges.

This symposium will: provide the latest information on AIDS and education; give guidance concerning the care of individuals, particularly children, who are infected with HIV; dispel the myths and cut through the confusion surrounding the disease; deal with the issues raised by the new National Curriculum.

There will also be a trade fair exhibiting the latest educational resources available.

This event is of immediate relevance to: Biologists, Teachers, Social Workers, Educationalists, Counsellors, Health and Education Volunteer Workers.

Discount for members of the Institute of Biology.
Please see insert in this issue of Biologist *or write to Jeremy Grange, Institute of Biology, 20 Queensberry Place, London SW7 2DZ*



Registration: £25.00 (Members: £22.50)

EUROPEAN INSTITUTE of TECHNOLOGY

INVITATION FOR RESEARCH PROPOSALS

THE EUROPEAN INSTITUTE OF TECHNOLOGY

invites research proposals to be funded in 1990.

The European Institute of Technology is an industrial consortium for research and higher education, organized by several leading international corporations. It seeks to strengthen innovation in Europe by increasing the effectiveness of industrial and university research and by forging a stronger industry-university partnership.

In 1989, the initial year of the EIT programme, 34 preliminary proposals from universities and institutes throughout Europe were chosen for Phase I funding. Following their elaboration and evaluation, the EIT announced on 4 July 1989 that nine had been selected for Phase II funding, representing a total of four million ECU.

In 1990, the EIT will fund research in the areas of information technology, materials technology and biotechnology/pharmacology. Researchers at European universities are invited to submit brief initial proposals for original research in any of these areas. The proposals will be reviewed by referees and panels of experts and some will be selected for further elaboration, with Phase I funding of ECU 5 000 to 10 000. A few of the resulting detailed proposals will then be selected for Phase II funding of as much as ECU 250 000 annually for three years.

Initial proposals should be submitted by 15th November 1989.

Instructions for preparing the proposals can be obtained from:

European Institute of Technology
Palazzo Diamanti — Via Noris 1 — 37121 Verona (Italy)
Telephone: +39-45-800 6433 — Telefax: +39-45-800 1225

CALL FOR
POSTERS AND SHORT REPORTS

"Advances in Gene Technology: The Molecular Basis of Immune Diseases"

January 21-26, 1990

The major gene technology conference of 1990 - **THE MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA** is announcing its call for poster presentations that will appear in the conference proceedings as Short Reports and will be published by the ICSU Press and IRL Press.

Poster sessions are scheduled for January 22,23, and 24, 1990 at which time you may present your reports on 4' high x 6' wide corkboards provided for the occasion The Short Report is the permanent record of your poster.

To have your Short Report considered for acceptance, you must be registered for the Symposia, and your Short Report must be received no later than **November 1, 1989.** Notification of acceptance will be sent within three weeks of the closing deadline.

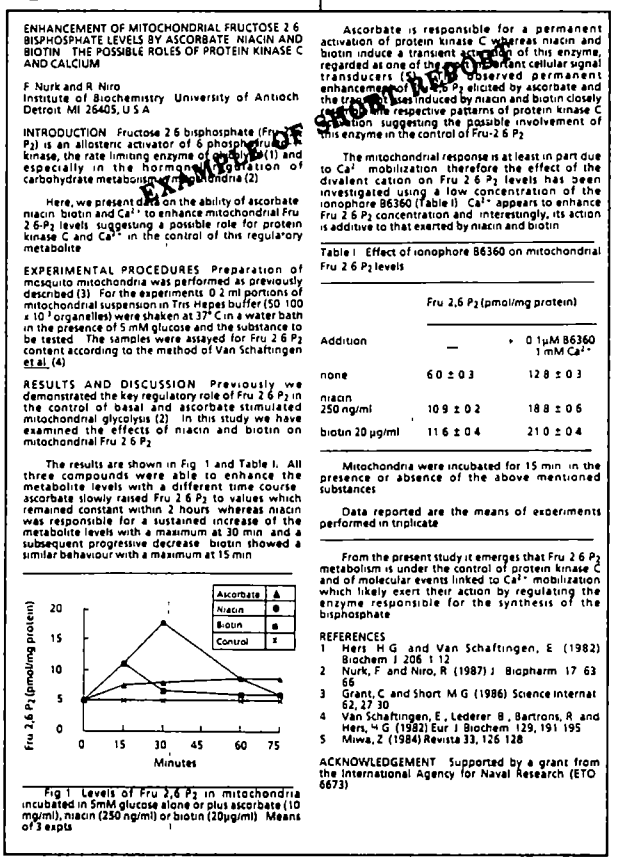
GUIDELINES FOR PREPARING SHORT REPORTS

To give your report the best chance of being accepted by the Symposia, try to follow these simple guidelines:

Legibility. The type style must be letter quality. Neatness counts.

Technical Specifications. Use the grid paper or type on two A4 or legal size sheets within a grid of 10 cm. wide and 28 cm. deep. Do not draw lines around your Report. Type size - 12 pitch Single space. Number the pages in pencil on the reverse.

Length of Report. Two columns (2 grids of 10 x 28 cm) equals one page. **You must occupy two (2) columns in order to be considered for publication.** Anything under or over will automatically be rejected.



Headings. Capitalize headings for major sections either by topic, or organizationally, e.g. INTRODUCTION, DISCUSSION, REFERENCES.

Subheadings. Use capitals for initials and underline the phrase

References. Cite these by number in the order in which they appear in the text. Collect the bibliography into a section at the end. **A bibliography is essential.**

Acknowledgements. These should appear last.

Make certain your work is represented at this important event. **Mail** your **UNFOLDED** Short Report to: MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA, P O. Box 016129, Miami, FL 33101, USA. (If using a courier service, to MIAMI BIO/TECHNOLOGY WINTER SYMPOSIA, Room 6054, Medical Research Building, University of Miami School of Medicine, 1600 NW 10th Ave., Miami, FL 33136, USA.)

ENHANCEMENT OF MITOCHONDRIAL FRUCTOSE 2 6 BISPHOSPHATE LEVELS BY ASCORBATE NIACIN AND BIOTIN THE POSSIBLE ROLES OF PROTEIN KINASE C AND CALCIUM

F Nurk and R Niro
Institute of Biochemistry University of Antioch Detroit MI 26405, U S A

INTRODUCTION Fructose 2 6 bisphosphate (Fru-2 6-P_2) is an allosteric activator of 6 phosphofructo-1-kinase, the rate limiting enzyme of glycolysis (1) and especially in the hormonal regulation of carbohydrate metabolism in mitochondria (2)

Here, we present data on the ability of ascorbate niacin biotin and Ca^{2+} to enhance mitochondrial Fru 2 6-P_2 levels suggesting a possible role for protein kinase C and Ca^{2+} in the control of this regulatory metabolite

EXPERIMENTAL PROCEDURES Preparation of mosquito mitochondria was performed as previously described (3) For the experiments 0 2 ml portions of mitochondrial suspension in Tris Hepes buffer (50 100 x 10^3 organelles) were shaken at 37° C in a water bath in the presence of 5 mM glucose and the substance to be tested The samples were assayed for Fru 2 6 P_2 content according to the method of Van Schaftingen et al (4)

RESULTS AND DISCUSSION Previously we demonstrated the key regulatory role of Fru 2 6 P_2 in the control of basal and ascorbate stimulated mitochondrial glycolysis (2) In this study we have examined the effects of niacin and biotin on mitochondrial Fru 2 6 P_2

The results are shown in Fig 1 and Table I. All three compounds were able to enhance the metabolite levels with a different time course ascorbate slowly raised Fru 2 6 P_2 to values which remained constant within 2 hours whereas niacin was responsible for a sustained increase of the metabolite levels with a maximum at 30 min and a subsequent progressive decrease biotin showed a similar behaviour with a maximum at 15 min

Fig 1 Levels of Fru 2,6 P_2 in mitochondria incubated in 5mM glucose alone or plus ascorbate (10 mg/ml), niacin (250 ng/ml) or biotin (20µg/ml) Means of 3 expts

Ascorbate is responsible for a permanent activation of protein kinase C whereas niacin and biotin induce a transient activation of this enzyme, regarded as one of the important cellular signal transducers (5) The observed permanent enhancement of Fru-2 6 P_2 elicited by ascorbate and the transient rises induced by niacin and biotin closely resemble the respective patterns of protein kinase C activation suggesting the possible involvement of this enzyme in the control of Fru-2 6 P_2

The mitochondrial response is at least in part due to Ca^{2+} mobilization therefore the effect of the divalent cation on Fru 2 6 P_2 levels has been investigated using a low concentration of the ionophore B6360 (Table I) Ca^{2+} appears to enhance Fru 2 6 P_2 concentration and interestingly, its action is additive to that exerted by niacin and biotin

Table I Effect of ionophore B6360 on mitochondrial Fru 2 6 P_2 levels

	Fru 2,6 P_2 (pmol/mg protein)	
Addition	—	+ 0 1µM B6360 1 mM Ca^{2+}
none	6 0 ± 0 3	12 8 ± 0 3
niacin 250 ng/ml	10 9 ± 0 2	18 8 ± 0 6
biotin 20 µg/ml	11 6 ± 0 4	21 0 ± 0 4

Mitochondria were incubated for 15 min in the presence or absence of the above mentioned substances

Data reported are the means of experiments performed in triplicate

From the present study it emerges that Fru 2 6 P_2 metabolism is under the control of protein kinase C and of molecular events linked to Ca^{2+} mobilization which likely exert their action by regulating the enzyme responsible for the synthesis of the bisphosphate

ONCOGENE

NEW JOURNAL

AN INTERNATIONAL JOURNAL

Editors: Graham Currie and John Jenkins, Marie Curie Research Institute, Oxted, Surrey, UK

Prem Reddy, The Wistar Institute, Philadelphia, USA

This new journal includes full and detailed papers as well as short communications relevant to all aspects of oncogene research, including the following topics: cellular oncogenes and their mechanisms of activation, structure and functional aspects of their encoded proteins, oncogenes in RNA and DNA tumour viruses, presence of oncogenes in human tumours, relevance and biology, cell cycle control, immortalization, cellular senescence, regulatory genes and "anti-oncogenes", growth factors and receptors.

The international editorial board draws upon a wide range of expertise from the UK, USA, USSR, Federal Republic of Germany, France, Canada and Israel.

INTERTEST-2

INTERTEST-4

FACTOR-TEST

N-TEST

INTERTEST-6

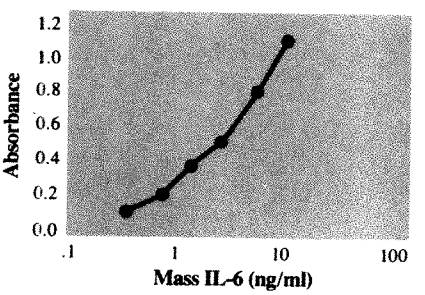
IL-6 ELISA Kit
A search made simpler.

The InterTest-6™ ELISA kit offers you a simpler method of measuring human Interleukin-6 (IL-6). For studying the role of IL-6 in the immune response, inflammation, or cancers, the InterTest-6 kit gives you everything you need and more:

Sensitivity: accurate IL-6 measurements in the range of 0.5–25 ng/ml.

Specificity: no detectable cross reaction with TNF-α, IFN-γ, IL-1, IL-2, IL-3, IL-4, G-CSF, M-CSF, or GM-CSF.

Time savings: results are ready within 24 hours—three times faster than bioassays.



Convenience: contains all necessary reagents including microtiter strip wells and easy-to-follow instructions.

InterTest-6 is the newest addition to Genzyme's innovative line of immunoassay kits for research use. And, like all of our cytokine products, it comes with technical support and our guarantee of performance. For more information or to place an order, call **1-800-332-1042** or outside the USA **1-617-876-9404.**

IL-6 Production in Cell Cultures as Determined Using InterTest-6

Cell Culture	Duration	IL-6 ng/ml
T-cell clone 1	24 hrs	< 0.3

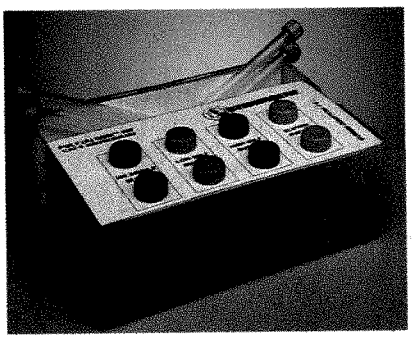
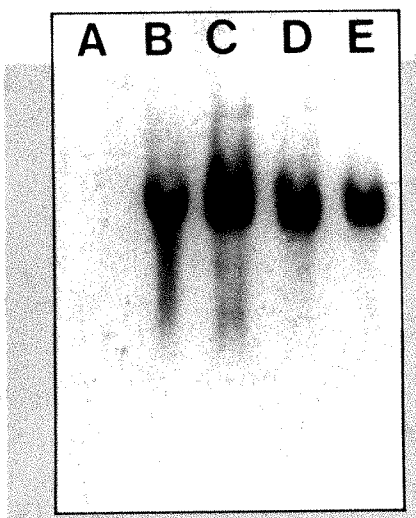
AND FAST.



Stratagene's Poly (A) Quik™ kit purifies polyA⁺ mRNA from total RNA in just minutes.



The ability to isolate messenger RNA molecules via polyA⁺ selection over Oligo (dT) cellulose has greatly facilitated the study of eukaryotic genes (1). Until recently, the protocol for Oligo (dT) cellulose chromatography involved the use of standard drip columns with a typical yield of only 1% mRNA (2).

Oligo (dT) spin columns were introduced to replace drip columns, reducing the total time required to 1 hour. Stratagene has now reduced that time to 15 minutes with the Poly (A) Quik™ push column.

Stratagene's new Poly (A) Quik™ kit allows rapid chromatography without the need for column preparation or centrifugation equipment. From start to finish, poly A⁺ RNA can be isolated from total eukaryotic RNA in less than 15 minutes with poly A⁺ yields equivalent to 2 to 3% of total RNA (3). Poly (A) Quik push columns and all of the necessary buffers are included within the kit.

For more info call Technical Services at 1-800-548-1113.

Total RNA was extracted from transgenic and non-transgenic mouse liver using the Stratagene RNA isolation kit. One mg of transgenic total RNA was passed twice over a Poly (A) Quik™ push column, and the poly A⁺ fraction was purified. Samples were electrophoresed on a VAGE™ vertical formaldehyde agarose gel, vacuum blotted, UV cross linked, and hybridized to a DNA probe to detect the presence of the transgene.

A: 5 μg non-transgenic mouse liver total RNA.
B: 5 μg transgenic mouse liver total RNA.
C, D & E: 500, 175 and 75 ng of poly A⁺ enriched RNA from the Poly (A) Quik™ push column.

Comparing the signal intensity in lane B with lanes C-E, shows that the Poly (A) Quik™ push column enrich RNA sample for poly A⁺ species over 50 fold.

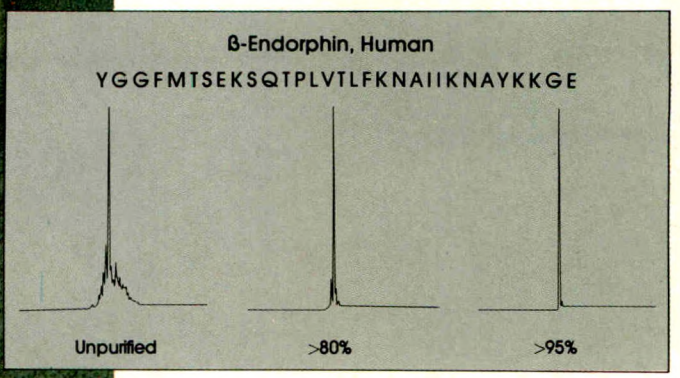
MYOSIN ISOZYMES IN DICTYOSTELIUM



NEW JOURNALS REVIEW

NOW Purified Peptides

MPS specializes in quality, custom peptide synthesis . . . so you don't have to!

In order to meet the differing needs of individual researchers, we are now offering three grades of peptides: unpurified, >80% purity and >95% purity. Additionally, for those using peptides to raise anti-peptide antibodies, MPS also provides a peptide carrier conjugation service. Call us with your questions or if you would like a complete price list.

COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

	Guaranteed Purity Level		
	Unpurified	>80%	>95%
Quantity	50-100 mg	30-50 mg	20-30 mg
10 mer	$400	$700	$1000
15 mer	$550	$850	$1150
20 mer	$800	$1200	$1600

CAN YOU SYNTHESIZE & PURIFY PEPTIDES FOR LESS?

Before you buy an automated peptide synthesizer, you should consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, purification, waste disposal, laboratory space, downtime and, of course, the initial cost of the synthesizer.

Multiple Peptide Systems
10955 John Jay Hopkins Drive, San Diego, CA 92121 USA

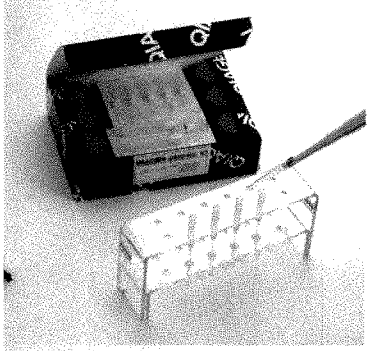
Hi purity >lambda< DNA

QIAGEN *Hi purity* >lambda< kits will dramatically change the way you isolate lambda DNA. The QIAGEN >lambda< kit series represents a complete purification system. Lambda kits are available for either Mini, Midi, or Maxi preps of lambda DNA, containing all buffers, reagents, protocols and the QIAGEN mini columns.

QIAGEN means:

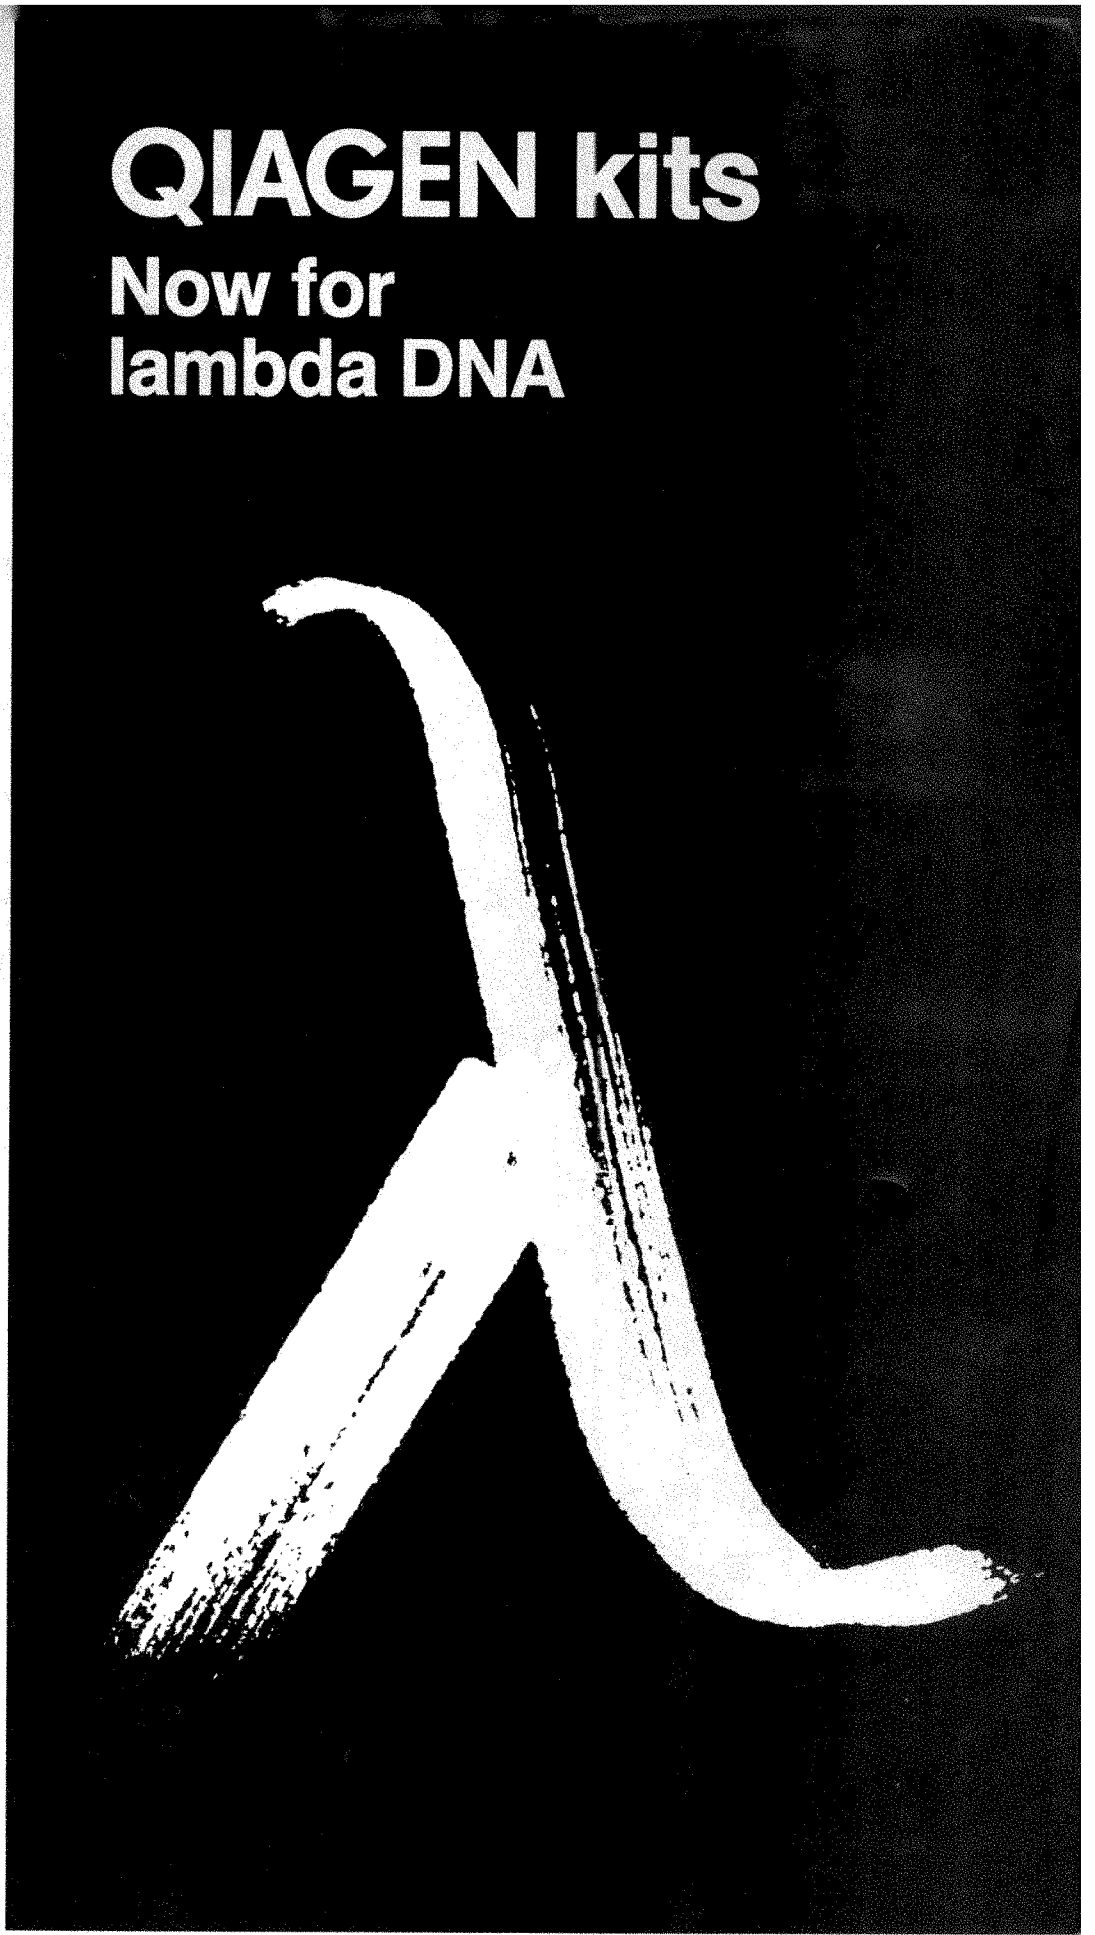
High Purity DNA
Speed and Convenience
No Phenol
No CsCl or Ultracentrifugation

With QIAGEN CsCl purity is equalled:



Pure lambda DNA can be isolated rapidly and economically using QIAGEN kits and easy-to-follow protocols. It is ideally suited for:

Cloning
Enzymatic processing
Sequencing



QIAGEN mini columns

contain our unique-anion-exchange resin QIAGEN that guarantees the selective isolation of different classes of nucleic acids, and the complete removal of proteins, polysaccharides and metabolites.

QIAGEN kits are now available for plasmid DNA and lambda DNA

- The Hardware Interface Card converts standard Hewlett-Packard Laser Printer output from 2 shades of gray to 225 shades of gray yielding Publication Quality Data.
- Print Text and Line Art at 300 Dots per Inch Resolution
- Output Ready for Journals, 35mm Slides, Overheads, Handouts
- Image Files Compatible with Linotronic Printers

U.S. Introductory Price Under $7,500.

System Includes:

- Scanner/Transilluminator
- Menu Driven Image Editing/Drawing/ Text Software
- Hardware Interface for Laser Printer
- Complete Instruction Manual

System Requirements:*

- 286 or 386 IBM-Compatible Computer with 4 Megabytes Additional RAM
- VGA Card and Compatible Monitor
- Mouse
- MS-DOS 3.0 +
- MS-WINDOWS 2.03 +
- Hewlett-Packard Laserjet II Printer

*Stratagene Cloning Systems offers these items separately or as a turn-key package.

Reader Service No.345

Announcing a unique RIA technology – it's in closer proximity than you think

- No liquid scintillation cocktails required
- Time saving
- Cost saving
- Increased safety
- High performance

Amersham introduces Scintillation Proximity Assays

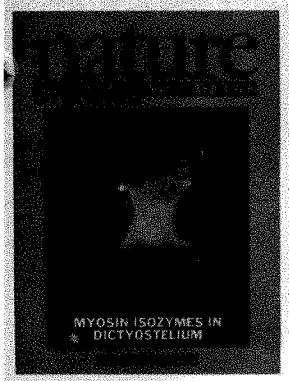
- No separation of bound from free required
- Simple to use; convenient protocol
- Readily automatable

Full details on the theoretical and technical aspects of scintillation proximity assays are given in our technical booklet 'Scintillation Proximity Assays — principles and practice', available on request.

Products available

- **Generic reagents** — for the development of in-house assays

	Ordering code
Scintillation Proximity Assay (SPA) reagent, anti-rabbit	RPN 140
Scintillation Proximity Assay (SPA) reagent, anti-mouse	RPN 141
Scintillation Proximity Assay (SPA) reagent, anti-sheep	RPN 142
Scintillation Proximity Assay (SPA) reagent, protein A	RPN 143



- **Assay systems**

6-Keto-prostaglandin $F_{1\alpha}$ [^{3}H] Scintillation Proximity Assay (SPA) system	TRK 952
Thromboxane B_2 [^{3}H] Scintillation Proximity Assay (SPA) system	TRK 951

Vol. 341 Issue no. 6240

◀ A double-stain immunofluorescence micrograph of a mitotic amoeba of the slime mould *Dictyostelium* shows filamentous myosin II (yellow) localized in the contractile ring, and myosin I (green) at the leading edges of the lamellipodia of daughter cells. Magnification X 80. See page 328

THIS WEEK

Underground map

The 'World Stress Map' is a project aiming to assemble a global database of *in situ* measurements of tectonic stress orientations in the Earth's crust. Such a resource will be of value in earthquake hazard studies, mining and petroleum exploration, and civil engineering projects. See this week's Review Article, page 291.

Taking the pulse

A technique for non-invasive measurement of vascular dynamics and elasticity would contribute to the understanding of diseases such as atherosclerosis and hypertension. On page 321, Behling *et al.* use stroboscopic NMR microscopy to produce the first microimages of a dynamic system,

Carotid artery in cross-section in systole (left) and diastole.

the carotid artery of the rat. This new method makes it possible to map the entire cardiac cycle, and also to examine the local activity of vasoactive drugs.

Mass X-rays

The X-ray emissions from supernova SN1987A pass through part of the Large Magellanic Cloud before reaching observatories on Earth, providing clues as to the properties of the interstellar medium in that region. Page 309.

Core curriculum

The cloning of the yeast protein that binds to the core eukaryotic promoter TATA sequence should lead to insights into the function of this important transcription factor. Pages 299 and 279.

Level of independence

The expression of exogenous genes in transfected cells and transgenic animals can vary with the chromosomal site of insertion. Sequences that have been defined as attachment sites linking genomic DNA to the nuclear scaffold are now shown confer an elevated level of expression on a reporter gene that is independent of the chromosomal site of insertion. Page 343.

Methane in the balance

Tropospheric methane levels are increasing by about 1 per cent a year — either because of increased production or decreases in global sinks. On page 314, Steudler *et el.* present measurements of methane uptake in aerobic temperate forest soils that suggest a greater role for nontropical forests in maintaining the methane balance than was previously suspected. In addition, nitrogen fertilization appears to reduce the effectiveness of this sink.

Filling the gap

During *Drosophila* embryogenesis, the first zygotic genes to be expressed are the so-called gap genes. The products of these genes are important in reading and interpreting positional information of maternal origin, and in determining the pattern of expression of other zygotic genes. On pages 331 and 335 it is reported that the protein products of the gap genes *hunchback* and *Krüppel*, are sequence-specific DNA-binding proteins involved in the zygotic gene regulation. On page 337, it is shown how three gap genes, *Krüppel*, *knirps* and *tailless*, interact during pattern formation in the posterior of the embryo, a process not directly instructed by maternal information. See News and Views, page 282.

Guide to authors

Facing page 291.

Nature® (ISSN 0028-0836) is published weekly on Thursday, except the last week in December, by Macmillan Magazines Ltd (4 Little Essex Street, London WC2R 3LF). Annual subscription for USA and Canada US$295 (institutional/corporate), US$125 (individual making personal payment). USA and Canadian orders to: *Nature*, Subscription Dept, PO Box 1733, Riverton, NJ 08077-7333, USA. Other orders to *Nature*, Brunel Road, Basingstoke, Hants RG21 2XS, UK. Second class postage paid at New York, NY 10012 and additional mailing offices. Authorization to photocopy material for internal or personal use, or internal or personal use of specific clients, is granted by *Nature* to libraries and others registered with the Copyright Clearance Center (CCC) Transactional Reporting Service, provided the base fee of $1.00 a copy plus $0.10 a page is paid direct to CCC, 21 Congress Street, Salem, MA 01970, USA. Identification code for *Nature*: 0028-0836/89 $1.00 + $0.10. US Postmaster send address changes to: *Nature*, 65 Bleecker Street, New York, NY 10012. NEW JOURNALS REVIEW

Publishing and perishing? John B Merriman 349

This issue contains *Nature's* annual review of new journals. The reviews begin on page 351, with an introduction and index on page 350. ▶

NEW DNA PROBES

(From the people who gave you Designer Genes™)

Human G-CSF

G-CSF stimulates neutrophilic granulocyte colony formation in semi-solid agar. Probes are available to exon 2, 3, 4 and 5.

Human GM-CSF

GM-CSF stimulates the proliferation and differentiation of specific bone marrow precursor cells. Probes are available to exon 1, 2, 3 and 4.

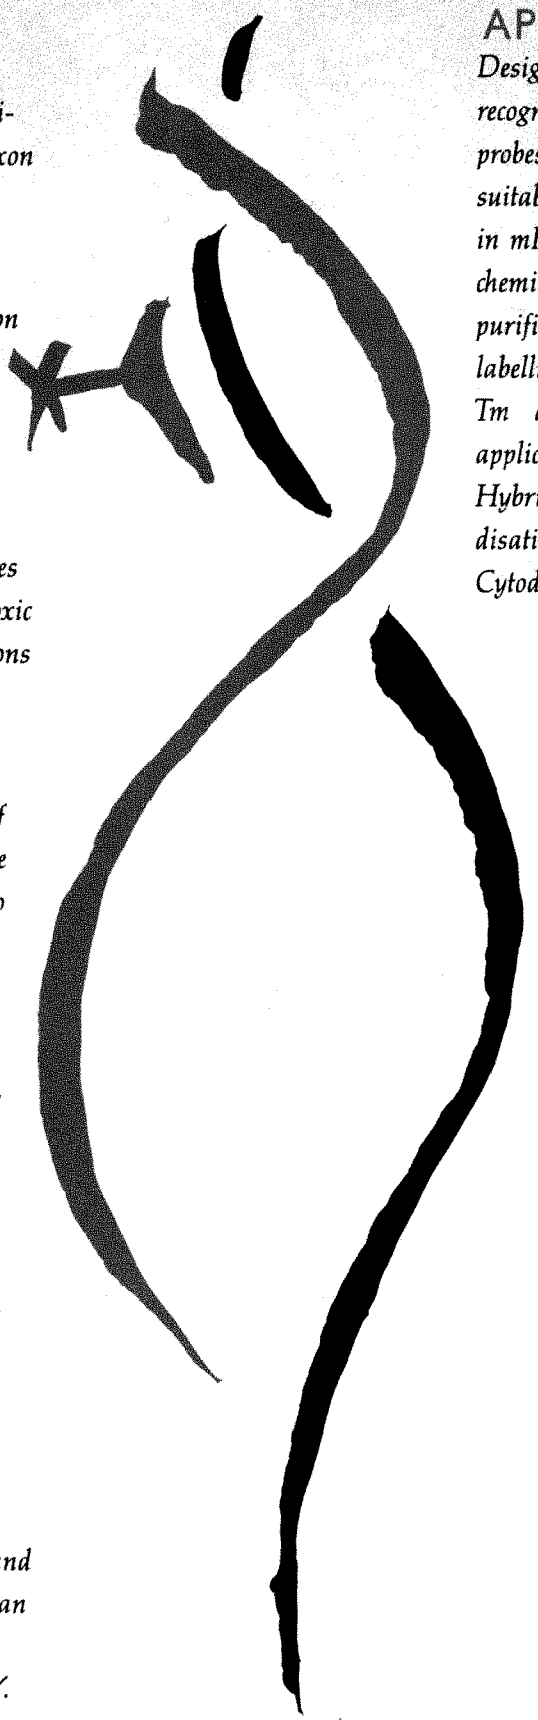
Human TNF ∝

TNF∝ has a wide range of activities on various cell types including cytotoxic functions. Probes are available to exons 3, 4A and 4B.

Human TNFß

TNFß shows most of the activities of TNF∝ and is thought to act via the same receptor. Probes are available to exon 3, 4A, 4B and 4C.

Rat c-fos



The c-fos protein may play a role in nuclear events associated with signal transduction. The probe hybridises to the 5′ region of the gene.

Rat Somatostatin

The somatostatin peptides inhibit the secretion of many different hormones. The probe hybridises to the SS-14 portion of the gene.

Rat Neuropeptide Y

NP-Y is one of the most abundant and widespread peptides in the mammalian nervous system. The NP-Y probe hybridises to exon 1 of mature NP-Y.

APPLICATIONS

Designer Probes™ from British Bio-technology recognise certain unique exons of genes. As the probes are antisense sequences they are also suitable for detecting the corresponding regions in mRNA. These probes are single-stranded, chemically synthesized and supplied ready purified with recommended protocols for labelling. The probes are of defined length and Tm and are suitable for the following applications. •Northern and Southern Hybridisation •Colony & plaque Hybridisation •In situ Hybridisation •Dot-blot & Cytodot Hybridisation.

PROBE COCKTAILS

Exon specific Designer Probes™ allow the identification of particular gene regions The exons selected are all contained in the region coding for the mature forms of the proteins. Also available are Probe Cocktails which consist of an equimolar mixture of exon specific probes. Probe Cocktails will pick up a combination of different regions of the gene and therefore show a higher level of sensitivity than individual probes. Probe Cocktails can be used for all the applications listed above.

Premiering January/February 1990!
A long-awaited unifying medium for virtually any practitioner of conjugation chemistry

Bioconjugate Chemistry

Editor: Dr. Claude F. Meares
Dept. of Chemistry, Univ. of California, Davis
Davis, CA 95616 (916/752-3360)

Centralized Access Is Here!

In *bimonthly* issues, **Bioconjugate Chemistry** will bring together important research findings in the fast-developing discipline of conjugation chemistry. Now—*in a single, time-saving source*—you'll find information which otherwise might be scattered throughout broader-focus scholarly journals.

The central theme of **Bioconjugate Chemistry** *is the joining of two different molecular functions by chemical or biological means.* This includes:

Conjugation of . . .
antibodies (and their fragments)
nucleic acids and their analogs (α-anomers, phosphonates, . . .)
liposomal components
other biologically active molecules (receptor-binding proteins, hormones, peptides, . . .)

with each other or with any molecular groups that add useful properties . . .
drugs, radionuclides, toxins, fluorophores, photoprobes, inhibitors, enzymes, haptens, ligands, etc.

There is *no* journal with this precise focus published today.

The Leading Edge In Biomedical Advances

Bioconjugate Chemistry will publish research at the core of many biotechnology enterprises, as well as of specific interest to biomedical firms, drug companies, and chemical laboratories.

Topics will emphasize the *chemical* aspects of *conjugate preparation and characterization . . . in vivo* applications of conjugate methodology . . . *molecular biological* aspects of antibodies, genetically engineered fragments, and other immunochemicals . . . and the relationships between conjugation chemistry and the biological properties of conjugates.

Guided by a "Who's Who" in the Field

Engineered to outlast the Great Pyramid

When the ancient Egyptians built their pyramids they had to take the long term view, and so engineered on a massive scale. Their engineers understood the objectives, and worked out the solutions from there. The results are plain to see thousands of years later. ☐ The engineers from UK Nirex Ltd. also have to take a long term view and engineer on a huge scale to make sure Britain's low and intermediate-level radioactive waste is kept safely out of man's environment while it fades away. ☐ Although the pyramids have stood for thousands of years we need to do even better, and so will put all our impressive engineering deep underground, at a thoroughly researched and understood site, where our technology will be backed up by the natural barrier of hundreds of metres of solid rock. ☐ This project will cost at least £1.6 billion and will serve the country's needs for 50 years. ☐ For further information write to The Information Office, UK Nirex Ltd., Curie Avenue, Harwell, Didcot, Oxfordshire, OX11 0RH. Or telephone Peter Curd on 0235 833009.

2. Associate Registration $_____
☐ Associate $25
Associates do not attend conference sessions, but may participate in receptions, tours, and other social and recreational activities

Associate name(s)

3. Placement Service $_____
☐ Employer—$100 ☐ Candidate—$10

Total Registration Fee (sum of 1, 2 & 3) $_____

Payment:
☐ Check enclosed (payable in U.S. $ only to Miami Bio/Technology Winter Symposia)

☐ Please bill my credit card. (Credit-card users may telefax this form to the Symposia at (305) 324-5665)
☐ American Express ☐ Visa ☐ Mastercard

Card number Expiration date

Signature as appears on card

You may pre-register until January 5, 1990. After that date, registrations will be taken on-site.

Sponsor's liability: Should this conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee.

Cancellation policy: All cancellations must be received in writing. Cancellations received on or before December 31 will be subject to a service charge of $25. No refunds will be made after that date. Registrants who are unable to attend may, if they choose, send a substitute.

NEW JOURNALS *From Alan R. Liss, Inc.*

Bimonthly beginning in September/October 1989

GENES CHROMOSOMES & CANCER

Felix Mitelman and Janet D. Rowley, Editors-in-Chief

Genes Chromosomes & Cancer offers rapid publication of original full-length research papers, short communications, concise invited reviews, as well as editorial commentaries on all aspects of genomic abnormalities related to neoplasia. Particular emphasis is placed on work combining molecular and cytogenetic analyses of the acquired genetic alterations of cancer cells. While preference is given to research utilizing analytical approaches, descriptive studies and case reports are welcomed, particularly when they offer insights regarding basic biologic mechanisms or the clinical management of neoplastic disorders.

Subscription information: Volumes 1 and 2, 1989/1990 as follows: Institutional rate, $180.00, Personal rate, $90.00. For all subscriptions outside the United States add $32.00 postage. Subscriptions outside North America will be sent by air. Subscriptions at the personal rate must be paid by personal check, bank draft, money order, or credit card.

Volume 2, 6 issues, 1990
Official Journal of the Human Biology Council

AMERICAN JOURNAL OF HUMAN BIOLOGY

Francis E. Johnston, Editor-in-Chief

The **American Journal of Human Biology** provides an international forum for the publication of papers furthering our knowledge of human population biology. In particular, the journal seeks consciously to integrate research in specialized scientific disciplines with issues of relevance to all who are interested in the biology of human variation.

ISSN 1042-0533

Subscription information: Volume 2, 1990, bimonthly: $96.00. For all subscriptions outside the U.S. please add $51.00 postage. Subscriptions outside North America will be sent by air. Members of the Human Biology Council receive the journal as part of their membership.

Indexed by: BIOSIS Data Base, Cambridge Scientific Abstracts

Volume 2, 4 issues, 1990

CHIRALITY

The Pharmacological, Biological, and Chemical Consequences of Molecular Asymmetry

Irving W. Wainer, Editor-in-Chief

Chirality is an international journal devoted to the study of molecular asymmetry and its role in both biologically and non-biologically active molecules. This authoritative publication emphasizes the pharmacological, biological, and chemical properties of chiral molecules with a focus on drugs, pesticides, and other xenobiotics. **Chirality** presents original papers reflecting recent research on the various aspects of chiral molecules, including their pharmacology, clinical pharmacology, toxicology and chemistry.

ISSN 0899-0042

Subscription information: Volume 2, 1990, four issues at the rate of $128.00. For all subscriptions outside the U.S. please add $34.00 postage. Subscriptions outside North America will be sent by air.

Indexed by: Chemical Abstracts, Excerpta Medica

Volume 3, 6 issues, 1990

Alan R. Liss, Inc. in cooperation with The University of Texas M.D. Anderson Cancer Center

MOLECULAR CARCINOGENESIS

Thomas J. Slaga and Stuart H. Yuspa, Editors-in-Chief

Molecular Carcinogenesis is a vital new journal devoted to the study of the molecular aspects of mechanisms involved in chemical, physical, and viral (biological) carcinogenesis.

ISSN 0899-1987

Subscription information: Molecular Carcinogenesis Volume 3 (6 issues, 1990): Institutional Rate: $190.00 U.S.; $241.00 outside U.S. Personal Rate: $90.00 U.S.; $120.00 outside U.S.

Indexed by: BIOSIS Data Base, Cambridge Scientific Abstracts, Excerpta Medica, ISI-Soviet Union

What in the world are you looking for?

In many fields of science and technology, people have learned to trust the quality and consistency of our products and services.

High-purity chemicals and reagents produced by BDH are a vital safeguard for the accuracy of work by those involved in advanced research and routine analysis alike.

The famous BDH AnalaR range of chemicals and reagents is recognised internationally: exceptional standards of purity are assured through our sophisticated production procedures, quality control and advanced testing techniques, which include inductively-coupled plasma emission spectroscopy.

New electrophoresis reagents have been introduced and a special range created for molecular biologists.

But while high-purity chemicals are a strong suit of BDH Limited we have other areas of specialisation – as you can see here.

These, too, can involve provision of modern materials, tools and products giving assistance to those involved in advanced analytical work, environmental testing, and scientific investigation at the frontiers of human knowledge.

BDH is a supply source for almost every kind of laboratory equipment. Our Advanced Materials Division produces monocrystals used for particle detection in high energy physics projects investigating the structure of the atom. We supply test systems to warn of pollution or unsafe inclusions in drinking water, rivers and reservoirs. Medical laboratories and hospitals are supplied with diagnostic materials and equipment, including those to aid early diagnosis of cancer, thereby assisting effective treatment and cure.

So BDH is a company that may well have exactly what you're looking for.

BDH Limited, Broom Road, Poole, Dorset BH12 4NN, England. Tel: (0202) 745520 Fax: (0202) 738299. Telex: 41186 or 418123 TETRA G.
A member of the **MERCK** group.

NEW JOURNALS FROM PERGAMON PHYSICAL AND ENGINEERING

Engineering, Materials Science & Energy

ADVANCED MATERIALS ABSTRACTS

1990: Volume 2 (12 issues) (878)
Will provide a comprehensive abstracts service for all advanced materials scientists covering areas such as polymers, composite materials, high technology ceramics etc. Also available on-line via ORBIT Search Service.

COMPUTER OPTICS (USSR)

1990: Volume 2 (2 issues) (912)
The first two issues will cover the following themes: Issue 1 - Fundamental physical principles of computer optics; Issue 2 - Software Terminology.

COMPUTING SYSTEMS IN ENGINEERING

1990: Volume 1 (4 issues) (916)
Communicates recent and projected advances in computational technology in engineering fields. Includes hardware, software, models and strategies, and applications to problems of analysis and design.

EXPERT SYSTEMS WITH APPLICATIONS

An International Journal
1990: Volume 1 (4 issues) (939)
This journal will focus on the exchange of information relating to expert systems applied in industry, government, and universities worldwide. The articles will discuss the design, development, testing, implementation, and/or management of expert systems, and also provide practical guidelines in the development and management of these systems. Of interest to engineers, developers, researchers, scientists and consultants involved with artificial intelligence.

MECHATRONICS

1990: Volume 1 (4 issues) (933)
Mechatronics is the much expanding field of engineering which integrates mechanical and electronic principles. The journal seeks to publish research progress in this field with an emphasis on the applied rather than the purely theoretical, it will also serve the dual role of bringing greater recognition to this important area of engineering.

NONWOVENS ABSTRACTS

1990: Volume 2 (12 issues) (921)
A new abstracts service for the expanding nonwovens industry produced by PIRA. Also available online via ORBIT Search Service.

WELDING ABSTRACTS

1990: Volume 3 (12 issues) (934)
Over 500 abstracts are produced each month, written especially for the needs of the welding community. The abstracts are added to WELDASEARCH, the welding institute's database, available online exclusively via ORBIT Search Service.

WORLD CERAMICS ABSTRACTS

1990: Volume 2 (12 issues) (879)
Provides the fastest abstracts service available on ceramics research. Also available online via ORBIT Search Service. Coverage will include all raw material processing, plant development, ceramic processing and applications.

Physical Sciences

ASTRONOMY QUARTERLY

1990: Volume 7 (4 issues) (938)
Examines the role of astronomy, with an emphasis on cosmology, in natural philosophy and in culture in general, as well as astronomy's influence upon the intellectual atmosphere of the epoch. *Astronomy Quarterly* features in-depth, non-technical articles written by professional scientists for the educated layman and student.

IN THE SCIENCES

QUATERNARY INTERNATIONAL

The Journal of the International Union of Quaternary Research
1990: Volumes 5 - 8 (4 volumes) (865)
A high quality scientific publication under the auspices of the premier Quaternary Association, which will reflect the interdisciplinary nature of INQUA and records recent advances in Quaternary Science that appeal to a wide audience. Will publish collected research papers from symposia, workshops and meetings sponsored by INQUA's Commission, Sub-Commission and working groups.

TETRAHEDRON: ASYMMETRY

1990: Volume 1 (12 issues) (937)
Tetrahedron: Asymmetry will publish experimental or theoretical research results of outstanding significance and timeliness in the field of asymmetry in organic, inorganic, organometallic and physical chemistry and its application to related disciplines, especially bio-organic chemistry. Topics include the physio-chemical and biological properties of enantiomers, asymmetric synthesis, resolution, chirality recognition, analytical techniques for determination of absolute configuration, and molecular graphics and modelling methods.

GENE MANIPULATION IN BIOLOGY AND HUMAN DISEASE

9–10 November at the Cavendish

BOOK NOW WHILE PLACES REMAIN

How readily can the genes responsible for predisposition to conditions such as ischaemic heart disease or schizophrenia be identified? What are the prospects of human gene therapy? Are transgenic animals the key to understanding the precise genetic control of development? How much more sophisticated can methods of genetic manipulation and gene identification become?

These are among the major questions that will be addressed by the distinguished speakers at Nature's 1989 conference. A chairman will outline the context and aims of each session, the speakers will review their area of expertise and report the latest advances, and a rapporteur will draw out the implications of each session. There will be a panel discussion of the ethical and legal problems raised by human gene research and therapy. For the convenience of delegates, the second day of the conference will finish in mid-afternoon, whereas the first day will be extended by the panel session followed by a wine and cheese reception.

We expect the conference to sell out well before opening, so urge you to make sure of your place now by returning the form below.

CONFERENCE SESSIONS

1 HUMAN GENETIC DISEASE

James Crow, U. of Wisconsin (chairman)
Louis Kunkel, Harvard Medical School
Gerd Utermann, University of Innsbruck
Kenneth Kidd, Yale University
Eric Lander, Whitehead Institute (rapporteur)

2 PROSPECTS FOR GENE THERAPY

Leon Rosenberg, Yale (chairman)
Irving Weissman, Stanford University
Richard Mulligan, Whitehead Institute
French Anderson, NIH
David Baltimore, Whitehead (rapporteur)

3 HUMAN GENE RESEARCH: PANEL DISCUSSION

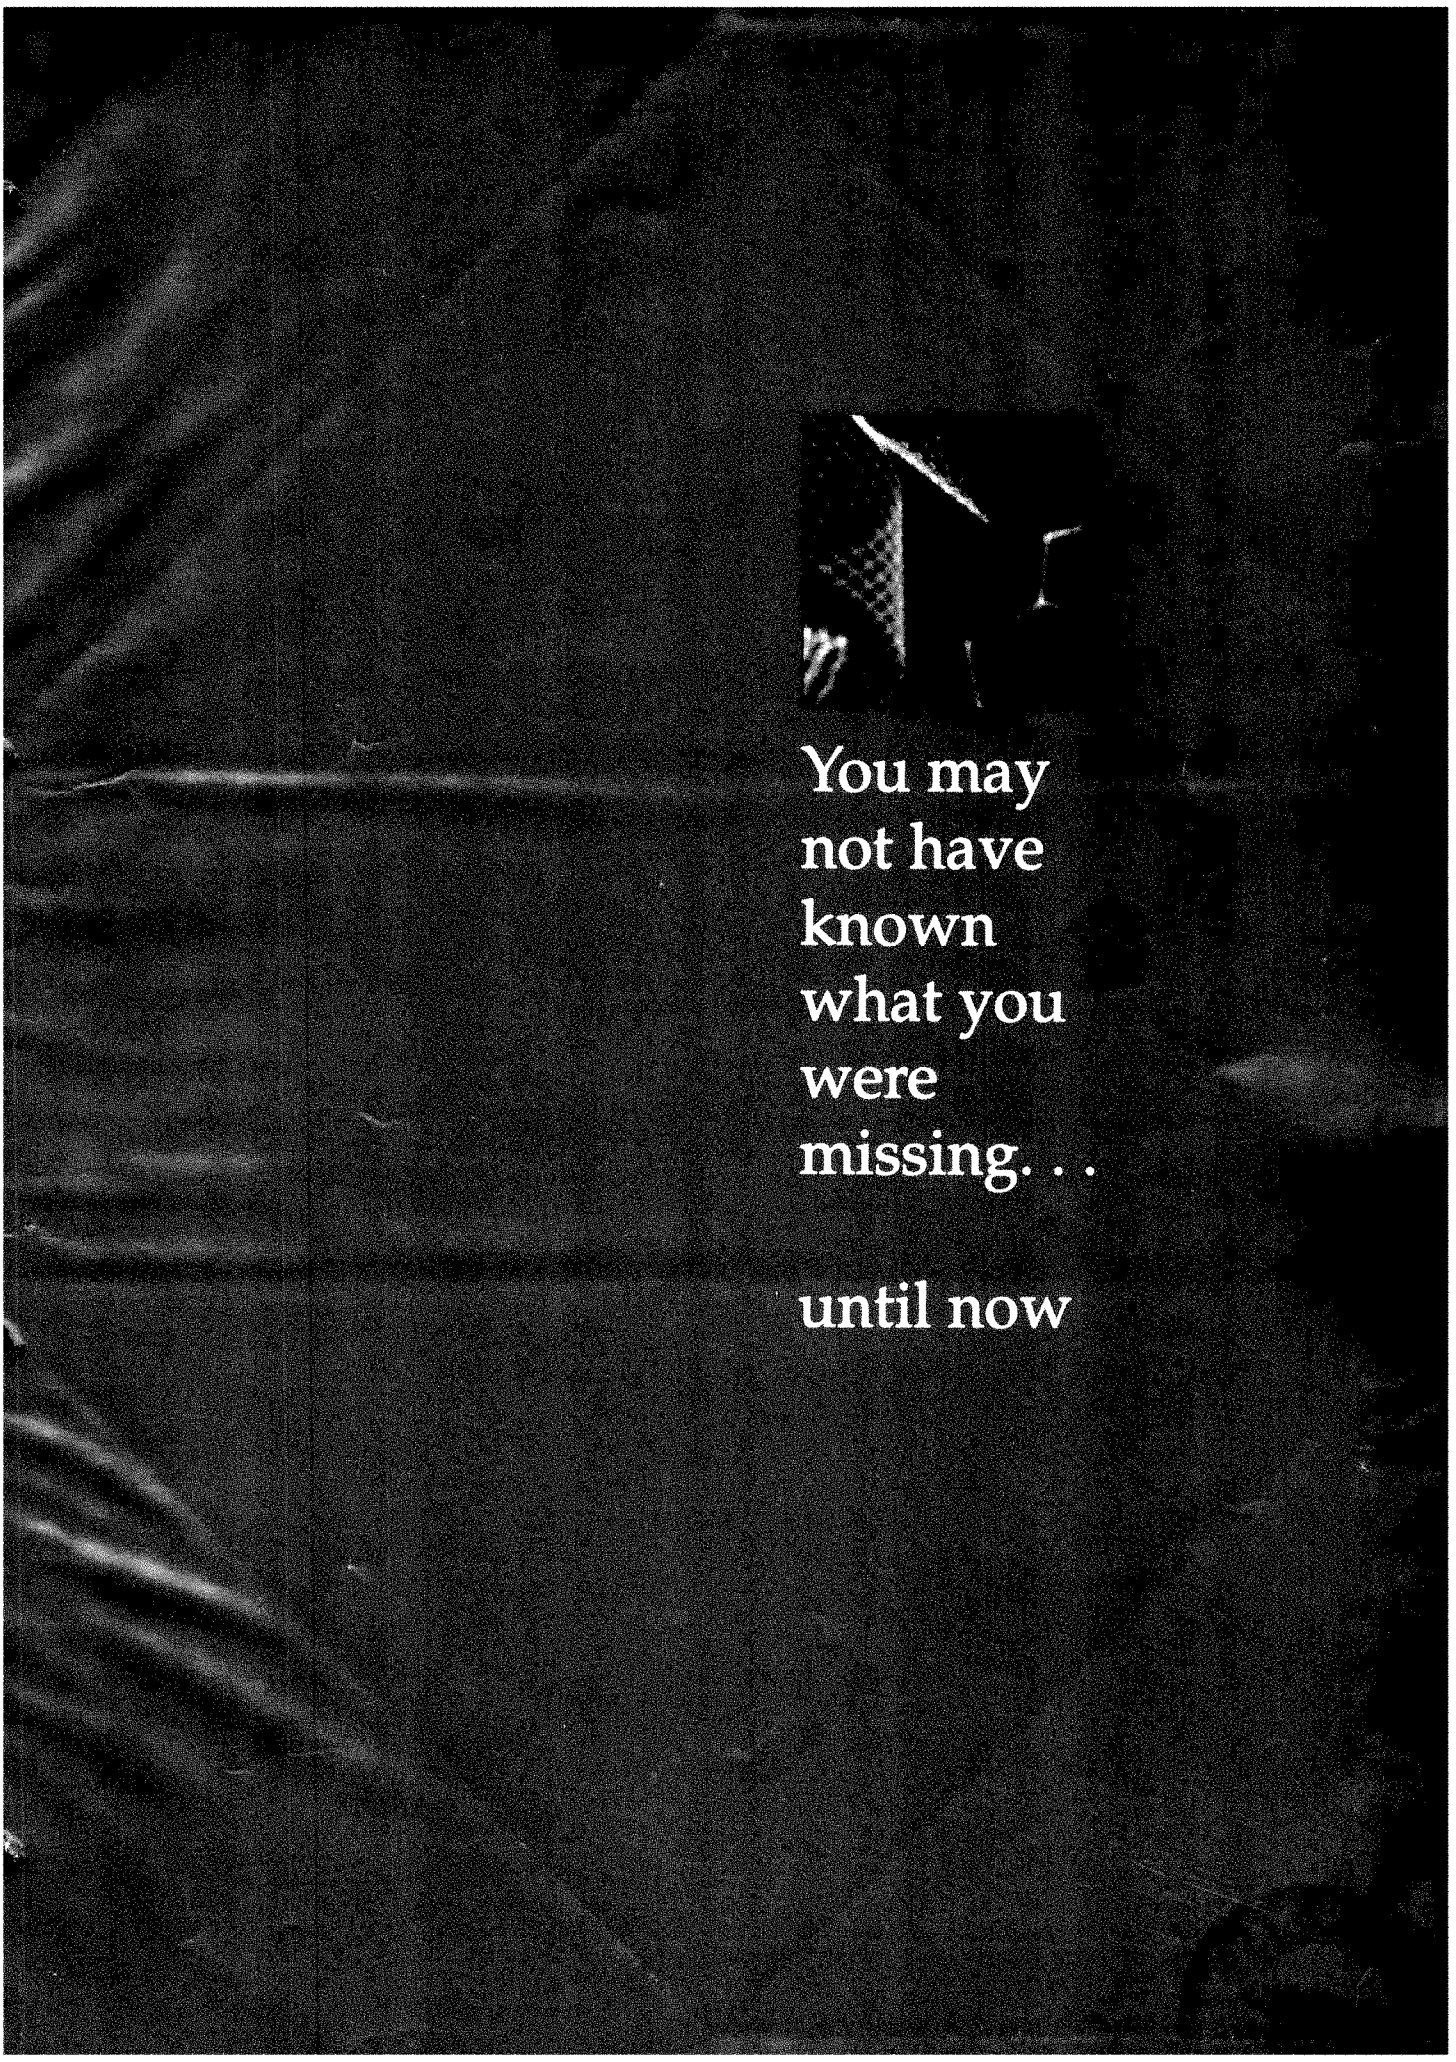
4 TRANSGENIC MOUSE MODELS

Richard Palmiter, Washington U. (chairman)
Douglas Hanahan, University of California SF
Erwin Wagner, IMP Vienna
Ron Evans, Salk Institute
Brigid Hogan, Vanderbilt U. (rapporteur)

5 GENE DISRUPTION AND DEVELOPMENT

Mario Capecchi, U. of Utah (chairman)
Fred Alt, Columbia University
Janet Rossant, University of Toronto
Peter Gruss, Max Planck Institute Gottingen
Bruce Alberts, U. of California SF (rapporteur)

GENE MANIPULATION IN BIOLOGY AND HUMAN DISEASE: 9–10 November 1989



REGISTRATION FEES
Standard rate including reception $350
Special rate for full-time academics and government employees only $300

Sponsor's liability: should the conference be cancelled or postponed for any reason, the sponsor's liability is limited to the return of the registration fee. Cancellation policy: all cancellations must be received in writing. Cancellations before 30 August will be subject to $25 service charge. No refunds will be made after that date. Registrants unable to attend may send a substitute.

BIOCHEMISTRY

Mathews and van Holde

Clear, current text that places chemical processes in biological context.

A new generation of art that shows original views as well as classic ones.

Special sections called "Tools of Biochemistry" that explain experimental techniques.

Christopher K. Mathews is Professor and Chairman of the Department of Biochemistry and Biophysics at Oregon State University. He holds a B.S. from Reed College (1958), and a Ph.D. from The University of Washington (1962). Dr. Mathews was an Eleanor Roosevelt International Fellow at the Karolinska Institute in Stockholm in 1984-85. Dr. Mathews has published over 100 scientific papers dealing with molecular virology, metabolic regulation, nucleotide enzymology, and biochemical genetics. He is the author of **Bacteriophage Biochemistry** (1971) and coedited **Bacteriophage T4** (1983). He and K. E. van Holde have taught the DNA-Protein Interactions course together at Oregon State University for 8 years.

K.E. van Holde is Professor of Biochemistry and Biophysics at Oregon State University. He earned his degrees from The University of Wisconsin (B.S. 1945, Ph.D. 1952). Dr. van Holde's major research interest is the structure of chromatin; his work resulted in the award of the American Cancer Society Professorship in 1977. He was named Distinguished Professor in 1988. He is a member of the National Academy of Sciences, and has received Guggenheim, NSF, and EMBO fellowships. He is the author of over 150 scientific papers; two books, **Physical Biochemistry** (1971, 1985), and **Chromatin** (1988); and the coeditor of **The Origins of Life and Evolution** (1981).

Poster: Dimer of *trp* repressor protein, with bound tryptophan (in blue). The protein binds to DNA and regulates expression of the *trp* genes. Crystal structure by Paul Sigler et al.; image by Jane and David Richardson.

Quantikine™

For the Precise Quantitation of Cytokines.

ELISA Kits for TNF-α, IL-1β*, IL-4*, IL-6

R&D Systems' Quantikine series of cytokine assays provides a sensitive, extremely accurate determination of the amount of a given human cytokine in cell culture media, sera and other fluids.

Each Quantikine kit features:

- A 96 well, 12 strip plate, *pre-coated* with a monoclonal capture antibody.
- A directly conjugated detection antibody.
- Complete reagents for testing of serum and tissue culture samples.

FOR RESEARCH USE ONLY
NOT FOR DIAGNOSTIC OR THERAPEUTIC PROCEDURES
*Available October 30, 1989

Sensitive: linear in the range of 20-2000 pg/ml; minimal detectable amount <10 pg.

Precise: well-to-well CV <8%

Specific: results not influenced by the presence of other cytokines.

Accurate: eliminates the inherent imprecision of bioassays.

Rapid: simple 7 step procedure, data in <4½ hours from receipt of kit.

Add sample...Incubate (2 hours)...
Wash...Add Detection Antibody...
Incubate (2 hours)...Wash...
Develop...Read Results.

The most accurate and up-to-date guide to the status and development of human therapeutic proteins . . .

Genetically Engineered Human Therapeutic Drugs

D. Copsey and S.Y.J. Delnatte, *Pantech Partners*

Genetically Engineered Human Therapeutic Drugs is a comprehensive reference source that provides up-to-date information on human therapeutic proteins in a convenient, logically organized format. Based on evidence from clinical studies reported in the academic, clinical and biological research journals, the information provided in this work is among the most accurate and objective information available.

PART I: Clinical Drug Development
Part I consists of reviews of 77 proteins under 18 therapeutic categories. These reviews examine the clinical research being undertaken in the major unsatisfied therapeutic areas. Where available, each review provides information on: Therapeutic Indications • Clinical Research Background • Clinical Studies.

PART II: Commerical Drug Development
Part II examines 90 proteins under 25 therapeutic categories currently being developed for their commercial potential as therapeutic drugs. It is organized alphabetically by generic rDNA protein. Following the introductory section for each protein, are tables organized by stage of development: Launched Products • Registered / Approved Products (Not yet launched) • Products in Clinical Trials • Products in Research or Pre-Clinical Development • Products under Clinical Agreements

How to manage a peaceful world?

With luck, and chiefly because of Mr Mikhail Gorbachev's persistence, there is now a chance that peace will break out. Will the United States, the Soviet Union and their allies be able to manage the transition?

WYOMING, a remote but attractive state, has been in its time one of the most substantial bases for US ballistic missiles, but last weekend's meeting there between the US Secretary of State, Mr James Baker, and his opposite number from the Soviet Union, Mr Eduard Shevarnadze, could well hasten the end of the state's strategic importance. The crucial development is the Soviet Union's now-declared willingness not to make the abandonment of the Strategic Defense Initiative (SDI) a condition of a treaty to limit the deployment of strategic weapons, while insisting that the United States must agree to the strict interpretation of the Anti-Ballistic Missile (ABM) Treaty by which the two superpowers undertook not to "develop, test or deploy" ABM systems based at sea or in space. On the face of things, the US administration is prepared to accept this limitation; Baker would have said so were it not. So there is a substantial prospect of an agreement at some stage next year that Soviet and US forces of strategic weapons will be reduced by half. By any tests, that will be well worth waiting for.

But that seems not to be the end. President George Bush's plan to announce this week a new development towards a treaty to ban the manufacture of chemical weapons has been well flagged, and could imply more good news ahead (see page 271). And the British government, among others, has been making cheerful noises about the likelihood of reasonably quick progress in the negotiation at Vienna of a treaty on conventional weapons in Central Europe. The only obviously missing ingredient is a test-ban treaty. Only a little reflection will conclude that there has not so far this century been a time when there was such a substantial promise that arms-control agreements would not be ends in themselves but means towards the more enduring end of reducing, perhaps even eliminating, the risk of another world war. Even the rash of treaties agreed between 1968 and 1972 could not be said to have accomplished that.

Most of the credit for these developments must go to Mr Mikhail Gorbachev, who has often bemused his counterparts in the West with proposals for arms-control agreements at once daring and challenging. It is easy to forget that it is only a few years since Gorbachev at Helsinki almost persuaded his US counterpart, President Ronald Reagan, that the time had come to get rid of strategic weapons altogether. But, recognizing that it takes two (at least) to reach an agreement, Gorbachev might have talked until he was blue in the face. What has made the difference, this time, is *glasnost*, conceivably conceived of as an instrument of social equity (free speech) or, more deviously, as a means by which local and regional party chiefs within the Soviet Union might be confronted with their constituents' complaints, which has turned out to be a way of signalling that the superpower Soviet Union has paid a bankrupt's price to remain a superpower: there are missiles in the bunkers, but there is no butter in the shops.

Soviet citizens (in whichever Soviet republic they live) should acknowledge how temperate has been the response. At no stage in the four months just past, made particularly informative by the first session of the new Supreme Soviet (otherwise the Congress of People's Deputies), has there been a Western voice of substance demanding armed incursion (or even subversion) of the East; the flimsy doctrine that it is safest to attack an adversary when he says he is flat on his back appears to have been forgotten. There are two explanations, of which the full bunkers are the most immediate. The other is that the West is genuinely at a loss to know how to accommodate the certain prospect of fluidity in the East. Of course, it is no surprise that even Western sophisticates have lost the habit of living without national chauvinism.

Euphoria, the known enemy of realism, must also be contained. What this weekend's meeting in Wyoming confirmed is simply that the US administration is prepared to let SDI wither on the vine; the research will continue, but under other line items of the US defence budget. It will probably be the same in the Soviet Union, empty supermarket shelves notwithstanding. But both superpowers will be helped if the cost of military procurement can be reduced. That is Gorbachev's declared intention, but Bush should have similar objectives. Both should also acknowledge that their agreement, by proxy, in Wyoming does not legislate for other governments, those of South-east Asia, the Indian subcontinent and the Middle East (not to mention China and even Latin America). Who will be allowed to inspect those missile sites and weapons production plants?

There is also a more subtle social difficulty to be resolved: people in the West may welcome, for example, Moldavian linguistic nationalism as a sign that the empire in the East is in the process of collapse, just as people in the Soviet Union may applaud the Irish Republic Army

(which killed eleven British Marine bandsmen last week) as a bunch of freedom fighters. But, in reality, neither side would welcome the reality of those movements in the world that the arms-control agreements now in prospect are likely to create. The trick they must next pull off is to share the other's view of what constitutes good government. Necessarily, that will be more difficult than mere arms control. □

Defensive business

The failure of a British company's investment in a US business should be followed by more general reform.

SINCE the beginning of the year, the British Ministry of Defence has been brooding on the question of whether the General Electric Company (no relation of GE) and Siemens of West Germany should be allowed to buy the electronics, telecommunications and defence company called Plessey. Throughout, the ministry has been comforted by knowing that even if two of its chief electronics contractors merged, competition would remain because of the continued independence of Racal and Ferranti, the second of which, despite its reputation for daring, has a solid reputation in avionics. But no longer. Hardly had Plessey been taken over than Ferranti was in trouble.

The circumstances are bizarre, but also raise important questions about the role of modern contractors. Ferranti's troubles stem from its purchase more than a year ago (for £360 million) of the US defence contractor International Signal and Control (ISC). Ferranti's objective was to buy its way into a more substantial (and presumably more profitable) defence business than the British government offered. Eighteen months went by before it emerged that ISC does not, as it had claimed, enjoy the benefits of contracts worth between £150 million and £200 million with governments outside the United States. Ferranti's bankers have bridged the gap, but only temporarily; eventually, it will probably be sold.

The important public issue is that ISC appears not to have been one company, but two. Like all other public companies, it had a publicly acknowledged board of directors. But because much of its work was technically secret, there was a parallel 'proxy' board, one of whose members was (and still is) the much-respected ex-admiral "Bobby" Inman. The idea seems to have been that the latter, with the benefit of the appropriate security clearances, would talk technicalities to the Pentagon and other customers, presumably directing technical operations as well, while the public board would worry about matters that more usually concern directors — cash flow, the share price, corporate and public relations. Nobody (not even Ferranti) seems to have appreciated that such a division of responsibility, itself a violation of the principles of a joint-stock company, is also a recipe for not being able to tell who is responsible when things go wrong. It is a pity that Ferranti should have had to pay such a heavy price for demonstrating such a simple truth. □

We're all Greens now

If British Greens in conference last week are anything to go by, the Green movement has a problem of consistency.

LARGELY because of the continuing schism between the two British centre parties, the British Green party did better than anybody (itself included) expected at the British elections to the European Parliament in the summer. It is, of course, a familiar *canard* to say that Greens do not know what they want: the truth is that their wants are clearly articulated. But the British Green party's conference last week at Wolverhampton (a distant north-western suburb of Birmingham) seems merely to have confirmed that Greens' wants are a self-contradictory collection of yearnings for a different world that cannot constitute a political programme, but which may yet win votes.

Last week's conference reached largely predictable decisions. Nuclear power stations, for example, were condemned. So, too, was nitrate in drinking water, as were pesticides anywhere. Congestion on the roads could be made to disappear by levying sufficiently heavy charges on the vehicles using them. And so on. As the week went by, it became plain that it is unfair to call the British Green party a single-issue party; rather, it is a multi-issue party, an umbrella beneath which the discontents of all individual members can be accommodated. It is a party of the malcontent. Comparisons with the defunct French Poujadistes (who wanted not to pay taxes) are natural, and not misplaced.

It will be a great misfortune if the new 1990s' wave of environmentalists is too much enmeshed in doings such as these. In an environment more beneficent (at least for people) than ever before, there remain a few important environmental problems (such as AIDS and the possibility that the greenhouse effect will take effect) and a multitude of environmental threats less damaging to people (but not necessarily less threatening to other species), most of them consequences of human activities made possible by increased prosperity. Last week's Greens seem not to have bothered with the distinction.

In reality, all electable political parties have to square a tricky circle: they have to persuade those who vote for them that certain goals (AIDS and the greenhouse effect, say) are paramount and that others are matters on which people must be prepared to compromise. It is, for example, entirely possible that future governments in Europe and North America will find themselves having to relax drinking water standards so as to pay for capital investments needed to combat the greenhouse effect. And how much will Greens be prepared to pay to buy out last week's declaration by four southern African governments that they will continue to allow the trade in elephant ivory? Faced with such dilemmas, on last week's showing, the British Green party would promptly fall apart. □

Row over controversial new AIDS drug

■ Doctors enraged by *ad hoc* trial
■ Benefits claimed by patients

San Francisco

A HIGHLY controversial 'clandestine' study indicates that the promising AIDS drug Compound Q is not the cure many had hoped but, rather, one potentially useful — but extremely toxic — weapon in the growing arsenal being brought to bear against the disease.

The San Francisco advocacy group Project Inform established the trial last May after *in vitro* studies showed that Compound Q selectively killed cells infected with HIV, the virus causing AIDS. Organizers argued that patients had already begun to taking the drug on their own initiative and that federal safety and efficacy trials were proceeding too slowly. The *ad hoc* trial outraged many doctors and researchers, who felt that it undermined traditional science. And last week's announcement of the first results further emphasized the split over the issue.

Project Inform co-director Martin Delaney received a standing ovation when he proclaimed at a public meeting: "We have reported faster over this protocol than any research in the history of the epidemic". But Professor Jerome Groopman of Harvard Medical School condemned the effort. "This is an important and a very bad precedent", he said. "This is not the way we are going to identify effective treatments for AIDS." The trial's most conclusive data concerned the toxicity of the drug, which is derived from a cucumber-like plant and which has been used in China to treat cancer and induce abortions. Almost all the 51 patients in San Francisco, New York and Florida developed side-effects, ranging from fever and rash to violent dreams and coma. Three patients died after taking Compound Q, but researchers said all were in advanced stages of the disease and that no direct relationship could be established between their deaths and the drug.

On the positive side, many patients showed signs of benefiting from Compound Q. The Florida group was dropped from all except the toxicity data because doctors there used a wide range of dosages and administration methods that made comparisons impractical. But the 34 patients in San Francisco and New York generally showed an increase in the count of CD4 cells, which are depleted by HIV infection. Researchers were encouraged by several other findings. One involved P24 antigens, high levels of which are typically associated with an advanced stage of AIDS. Results of this test were announced only for the 19 San Francisco patients: 15 showed a decline and nine showed a sustained drop averaging 50 per cent. In addition, 12 of the San Francisco patients reported feeling more energetic than they had in months.

Nine gained weight and seven said they were mentally sharper. While trial organizers stressed that Compound Q is not a cure for AIDS, they insisted that it shows promise — especially if used with other drugs, such as AZT, which interfere with HIV's ability to infect new cells. Dr Alan Levin, who helped to organize the trial, said, "I believe that in combination with other drugs it has the potential for cure". Soon after the trial became public, the US Food and Drug Administration (FDA) launched an investigation, which is still continuing. Delaney claims that the trial is legal because it was established as a "treatment protocol" between doctors and existing patients, rather than a clinical study. Nevertheless, Project Inform took elaborate precautions to warn patients of the risks involved, both to assuage FDA fears and to avoid lawsuits.

A lawyer and a patient advocate were on hand as each subject signed the informed consent agreement — and the entire process was videotaped.

But opponents were unconvinced. "Martin Delaney and Al Levin are not competent to do experimental drug trials", said Groopman, who said he supports community-based research but not when it involves a highly toxic drug used for the first time in humans against a particular disease. He added: "It's quite likely patients unnecessarily suffered". Groopman attacked the trial on other grounds, challenging the protocol and criticizing the absence of a neutral third-party review. Delaney said trial results will be independently evaluated. But, in general, project organizers took a hard line with critics. Levin noted that patients often experience severe side-effects during FDA-approved trials. The difference, he said, is that the Compound Q results were quickly made public.

Besides, community physicians know best what is good for their patients, "Academic physicians are not qualified to care for the chronically ill", he added.

While the debate is yet to be resolved, more traditional work continues. An FDA-approved Phase I trial of Compound Q began in May at San Francisco General Hospital. And the National Institute of Allergy and Infectious Disease (NIAID) will soon announce funding awards under its new Community Program for Clinical Research in AIDS, designed to bolster community involvement in research. Said Daniel Hoth, director of NIAID's Division of AIDS, "Our view is that there's enormous energy and enthusiasm among community physicians to do clinical trials, and we want to help them channel that to productive research that can help find out which drugs work and which don't".

RADIOCARBON LABORATORIES

Blind dating exposes UK weakness

London

BRITAIN'S radiocarbon-dating laboratories are to launch an international project to try to overcome a lack of consistency in their results. A workshop held at the National Engineering Laboratory (NEL) in Kilbride, Scotland, heard last week that a comparison of 40 radiocarbon-dating laboratories in Britain found a disturbing pattern of errors.

Three Scottish laboratories, the Statistics Department of the University of Glasgow, the Natural Environment Research Council (NERC) Radiocarbon Laboratory in East Kilbride and the Scottish Universities Research and Reactor Centre, had collaborated to design, execute and interpret a "blind intercomparison exercise" supported by the Science and Engineering Research Council (SERC).

In the trials, 38 laboratories were asked to date samples of wood, peat and carbonate. Professor Murdoch Baxter of NEL said the results were "gloomy". He said that only seven out of 38 laboratories had met the three desired performance criteria — negligible bias, high internal precision and negligible external variation. Radiocarbon dates were "two to three times less accurate than implied by their error terms". He said most laboratories produced differing dates when they analysed similar objects of the same age.

Baxter said that although delegates were "disappointed" by the results, there was a "positive determination to work together and improve the situation" and the carbon-dating community "would adopt quality assurance principles and practice". Each laboratory will improve monitoring and build up a "record of regular essays of in-house and externally supplied reference standard materials". The International Atomic Energy Authority will supply samples of wood, sediment and carbonate on request from 1990 with given dates to provide reference materials. "There are a lot of good laboratories and a lot of poor ones", Baxter said. "It is important there is more cooperation to allow the good laboratories to help the others." To monitor improvements, a second blind check will be carried out in two years with the help of the NERC.

SCIENTIFIC FRAUD

False accusations at London hospital

London

FALSE accusations of fraud have been levelled at a British medical scientist at a London teaching hospital, apparently in an attempt to damage his reputation. The person accused (whose name is being deliberately withheld) holds appointments as a lecturer at the Royal Postgraduate Medical School (RPMS) and as a registrar at the Hammersmith Hospital, London, where the school is based.

One bizarre feature of the case is that letters to the school and to the Wellcome Trust, from which the scientist is seeking a scholarship, said that *Nature* had been conducting an investigation of several improprieties, including the forging of references in an application for registration to the General Medical Council and plagiarism of the work of other researchers in scientific papers submitted for publication. The letters are signed "John Dickson, for the Vanguard Detective Agency", and are constructed so as to suggest that the detective agency is employed in the investigation.

But in a letter to *Nature*, "John Dickson, PhD" merely suggests that an investigation should be carried out on the basis of the same and further allegations, including collusion with a travel agent to convert overseas travel funds into cash. There is no record of Vanguard Detective Agency, but the address in suburban west London from which the letters were sent is adjacent to an engineering workshop labelled "Vanguard Engineering Company".

Further allegations include the assertion that the accused scientist may have "fraudulently obtained his medical degree, that he was dismissed from a PhD course at Brunel University and that "the testimony of his fellow-workers" reveals that his conduct as a scientist is unethical. But the records office at Brunel University says there is no record of the accused scientist ever having been a student there.

Officials of the RPMS say they have the highest regard for the person accused, believing that he is at the start of a distinguished career. A senior member of the staff there says he has known the person's family for 30 years, and that the letters concerned must be a cruel hoax.

In the event, the author of the letter appears to be somebody who also holds an appointment at the Hammersmith Hospital. Earlier this week, he was under pressure to resign. An official of the Wellcome Trust said that the accusing letter might have been taken seriously, "and we might have found ourselves writing an unfortunate letter", had it not been for the "fishy" coincidence that the address given for the Vanguard Detective Agency is in the street in which the accused scientist lives.

JOURNAL COSTS

Battle over value of words

Washington

THE law courts of France, West Germany, Switzerland and the United States will provide the unlikely setting next year for a battle between two US publishers over the value for money offered by scholarly journals in physics. The battle began with a survey of the cost-effectiveness of physics journals published in the *Bulletin of the American Physical Society* and, in shortened form, in *Physics Today*. The commercial publisher Gordon and Breach, which emerged as the least cost-effective of those surveyed, claims that Henry Barschall, the author of the survey, was biased and the methodology was flawed. It is taking legal action against the American Physical Society (APS) and the American Institute of Physics (AIP) — the parent organizations of the two journals which published the survey — and against Barschall, in European countries where relevant laws are strict.

Barschall, a retired professor of physics at the University of Wisconsin in Madison, was prompted to examine the value for money of physics journals because their rising costs were forcing the university physics library to cancel subscriptions (see this issue page 349). He surveyed more than 200 physics journals, rating them according to cost and impact. Journals of both the APS and the AIP emerge among the most cost-effective.

Barschall measured cost-effectiveness as the ratio of the cost per printed character of a journal to the frequency with which it is cited, and found dramatic variations in the results. In the field of condensed-matter physics, for example, he reports that the cost-effectiveness varies by a factor of 200. "All the publishers whose journals have low average costs per character or low ratios of cost to impact are scientific societies or associations, while the publishers whose journals have high costs per character or high ratios of cost to impact are commercial firms." Barschall concludes that a solution to the present financial "crisis" in libraries caused by increasing costs of journals might be for authors to publish their papers in journals with low cost per character. In the survey, Gordon and Breach had the highest average ratio of cost to impact: 29.5 compared to 0.28 for the APS and 1.1 for the AIP, one of its member societies.

The lawyer representing Gordon and Breach in Switzerland, Alfred Gilgan, says this gives the impression that Gordon and Breach is a company of "crooks who are extorting their subscribers". The company has filed suits against APS, AIP and Barschall, seeking retraction, damages and an injunction preventing further articles comparing the physics journals of both publishers until the dispute is resolved. AIP offered to settle the dispute by publishing a response from Gordon and Breach in *Physics Today*, but this was rejected because the response was to be published along with a letter from Barschall.

Gilgan maintains that the article in *Physics Today* is a "disguised" advertisement for AIP and APS. "Barschall is not an independent scientist who conducted a survey in the interest of the science community", he says, claiming that Barschall is biased because of his links with AIP. For two years before he wrote the article, he was on the governing board of AIP. When he wrote the article, Barschall was still a member of the publishing policy committee of AIP, as was declared in a footnote to the article. Barschall denies the accusations of bias, saying that APS and AIP "had nothing to do with" the survey, and that he had no financial links with AIP or APS.

Gilgan also accuses Barschall of making "outrageous errors" in his calculations and using "misleading" methodology. The cost-per-character measure is too simplistic and "unjustly prejudices journals with a high content of formulae, graphs and charts", he says. Richard Meserve, one of the lawyers for AIP in the United States, disputes the claims, but admits that any method "is necessarily going to be imperfect". But Gilgan also argues that the costs calculated by Barschall for the Gordon and Breach journals were between 10 and 50 per cent too high, and accuses Barschall of choosing to survey the most expensive journals published by Gordon and Breach.

The measurement of 'impact' by a citations score is also criticized by Gilgan as a measure only of the circulation figure of a journal, not of its value to a subscriber. Highly specialized journals, such as those published by Gordon and Breach, have smaller circulation figures and thus higher production costs and subscription prices, he says, than general physics journals such as those of AIP. But "the characters that are actually useful to the subscriber are cheaper at Gordon and Breach than at AIP", he claims.

Barschall says that he used "standard" methodology and that he did not claim it was "the sole determinant as to what is a useful journal"; he wrote the article "from the point of view of a librarian" and "librarians need to know how much they have to pay to get a page of a journal". He also disputes that the journals of Gordon and Breach are more specialized than those of AIP and APS and that he selected those which are the most expensive. He surveyed, he says, all the physics journals to which he had "easy access" in the library.

Christine McGourty

SOVIET ARMED FORCES

Military hit by brain drain

London

THE Soviet armed forces are suffering from a temporary but acute brain-drain, Defence Minister General Dmitrii Yazov told an *Izvestiya* interviewer last week. The shortage, he said, is due to the early demobilization of students who had been called up for military service. Since for the most part student-draftees were assigned to jobs requiring a high level of technical expertise, their premature departure leaves serious gaps. More than 700 tanks and 900 infantry combat vehicles will be left without crews, and the rocket forces will have to go on to a watch-and-watch system instead of the present watch in three. It will take at least a year for the army and two years for the navy to make up the deficit.

The decision to release the students ahead of time came after several years' campaigning from rectors and faculty members of universities and higher education institutes who pointed out that national service interrupted a young man's career just when he was at the peak of intellectual creativity. Army service, they maintained, spoiled him for a scientific career, without for the most part making a good soldier out of him. The early demobilization of the students was widely hailed as the first step in the plan to reduce the Soviet armed forces by 500,000 men. Yazov now says, however, this is not so. The cuts, he explained, are being made by reducing the annual size of the draft intake. During the past six months, since the announcement of the cuts, the armed forces have been reduced by 148,900 men.

This figure does not include the 175,700 students, of whom some 168,000 have already returned to their studies. Yazov did not specify the criteria for reducing the intake. Possibly it is being done by raising health requirements. During the past few years, there have been frequent complaints about the physique of recruits, of whom almost one in ten fails the medical examination.

The gaps left by the students must once again raise the question of whether it would be more efficient to replace compulsory military service by a smaller, highly trained, professional army.

In the meantime, while the politicians and high command argue costs, much of the Red Army and Navy's most sophisticated equipment is apparently lying idle.

Vera Rich

HIPPARCOS

Rescue nearly over

Munich

PRELIMINARY results obtained last week demonstrated that the European Space Agency (ESA) astrometry satellite Hipparcos will yield some data, if not as much as originally planned. The perigee of Hipparcos's still very elliptical orbit (see *Nature* 341, 3; 1989) has been increased to 526 km above the Earth's surface, and its rotation has been stopped. ESA was intending to remove the protective baffles from the telescope aperture on 26 September.

On-board tests have indicated that the telescope and its instrumentation appear to be working. Except during the satellite's passage through the Van Allen radiation belts, 5,000 km above the Earth, the telescope's response was as expected, suggesting that Hipparcos will be able to return useful data 90 per cent of the time. Once the baffles are removed, it will be four weeks before ESA can gauge accurately the length of the mission. The current best estimate is that Hipparcos will survive six months, compared with the planned duration of two years.

Steven Dickman

PRIZES

USA, Japan and UK share research award

Washington

Four scientists share this year's Albert Lasker Basic Medical Research award, which recognizes their four individual discoveries of intracellular signalling pathways. Edwin G. Krebs, of the University of Washington, discovered protein phosphorylation, a fundamental biochemical reaction responsible for the progress of many enzyme reactions; Michael J. Berridge, of the University of Cambridge, was responsible for understanding the importance of calcium in cell growth, and its regulation by inositol triphosphate; Yasutomi Nishizuki, of Kobe University, elucidated the role of the enzyme protein kinase c, important in the regulation of both normal and abnormal cell growth; and Alfred G. Gilman, of the University of Texas, discovered G-proteins, a class of proteins that convey information from cell-surface receptors to internal cell processes.

The 1989 Clinical Research Award goes to Etienne-Emile Baulieu of the University of Paris, for his lifelong studies of the biological synthesis and functions of steroid hormones. Baulieu is publicly known for his discovery of the abortifacient drug RU486, which works by blocking the receptors for progesterone.

Lewis Thomas, of Cornell University, adds the 1989 Lasker Public Service Award to a number of book awards, for *The Lives of a Cell* and *The Medusa and the Snail*, and numerous honorary degrees. The Lasker citation recognizes Thomas for his promotion of biomedicine and public health not only through his popular writings but also by his activities as an administrator and teacher. Above, from left to right: (top) Edwin Krebs; Michael Berridge; Yasutomi Nishizuki; (bottom) Alfred Gilman; Etienne-Emile Baulieu and Lewis Thomas. **David Lindley**.

BLOOD PRODUCTS

Avoiding imports in Japan

Tokyo

PLANS are afoot to drastically re-structure the blood-product industry in Japan to reduce dependence on imported blood products which were the main source of AIDS infection. But the re-structuring could result in increased prices for blood coagulants for haemophiliacs, the main victims of AIDS in Japan.

A report released this month by an advisory body to the Ministry of Health and Welfare, the New Blood Business Promotion Study Council, recommends that all production of blood coagulants should be transferred from the private sector to the Japan Red Cross by 1991 and that coagulants should be made only from domestic blood. Until now, all coagulants have been made by private companies using mostly cheap US blood plasma. The report also recommends that more domestic blood should be used in the production of other blood products, such as albumin and globulin, and a new public organization should oversee the blood business in Japan.

Japan has come under international criticism for its excessive imports of blood products. In 1975, the World Health Organization (WHO) recommended that blood products should be made from domestic blood supplies. But by the mid-1980s, Japan's imports of blood plasma had grown to occupy about a third of the world market, and domestic blood supplied only a few per cent of demand. Coincident with this surge in the use of imported blood, AIDS was introduced to Japan in non-heat-treated blood coagulants made from US plasma and more than 90 per cent of AIDS carriers in Japan are haemophiliacs who were treated with such products.

The Ministry of Health and Welfare has tried to reduce consumption of blood products by discouraging unnecessary prescription by doctors. Consumption of blood plasma dropped from a peak of 3·8 million litres in 1985 to 2·7 million litres in 1987 but has since risen to 2·8 million litres in 1988. On a *per capita* basis, this is still more than twice the consumption of the United Kingdom and France, for example (see *Nature* **322,** 193; 1988).

The driving force behind blood consumption in Japan is huge discounting by pharmaceutical companies. The health and welfare ministry sets 'official' prices for drugs in April each year. But by using cheap imported blood plasma and blood products, companies have been selling blood products at far below the official price. Hospitals, which charge patients and the national health insurance system the official price, have been able to reap enormous profits by prescribing more and more blood products. The council report calls for production of cheaper domestic products to compete with imports. But experts express scepticism about the ability of the Red Cross to take over the blood coagulant business and produce cheap products.

A recent report in the Japanese newsletter *Nikkei Biotechnology* points out that the cost of blood plasma produced by the Japanese Red Cross (¥45 or out $0·3 per millilitre) is five times that of imported plasma and about seven times the price of plasma in the United States. Part of the reason for the high cost is that about 80 per cent of the blood is collected by mobile blood donation vans which are not cost effective. Unless the efficiency of blood collection is improved, the cost of domestically produced blood products is unlikely to fall.

The *Nikkei Biotechnology* report also doubts whether the Red Cross will be able to produce all blood coagulants by 1991. Although Japan has one of the highest blood donation rates in the world, most of the blood is used for transfusions, leaving little for production of blood-plasma products. The council report calls for blood donations to be increased from about 1·9 million litres in 1988 to 2·3 million litres in 1991 to supply the blood-plasma necessary for domestic blood-coagulant production.

But this target is insufficient if conventional methods of blood-coagulant production are used. A new monoclonal-antibody technique developed by Baxter pharmaceutical company in the United States gives a higher yield of blood coagulant and could perhaps meet Japan's domestic needs. The council report calls

IVORY IMPORTS

Japanese importers slide under the wire

Tokyo

IT seems to be impossible to stop Japan's ivory importers. In June, the Ministry of International Trade and Industry (MITI) announced a partial ban on ivory imports in the face of international criticism and concern about dwindling populations of elephants in Africa (*Nature* 340, 85; 1989). But no sooner was the partial ban announced than Japanese importers began stockpiling imported ivory on a large scale.

The stockpiling came to light after MITI announced on 13 September a "temporary" total ban on imports as part of a new import quota system intended to prevent exactly what has happened.

The earlier ban, affecting all imports of worked ivory, also banned indirect imports of raw ivory from suppliers in places such as Hong Kong and Singapore. Announced by MITI on 16 June, it took effect only three days later, but in the interval Japanese importers had placed orders in Hong Kong for about 20 tonnes of raw ivory, or about 20 per cent of Japan's annual use in recent years, according to Toru Takimoto of MITI's International Trade Administration Bureau.

Even after the partial ban took effect, direct imports from Africa continued, reaching by this month about 100 tonnes, or about as much as for the whole of last year. This stockpiling seems not to have been affected by the undertaking on 15 June to show "self-restraint by the several Japanese organizations involved in the import of ivory" (Japan General Merchandise Importers' Association, Japan Ivory Fine Arts and Crafts Cooperation Federation, Tokyo Ivory Fine Arts and Crafts Association and Osaka Ivory Fine Arts and Crafts Association).

The stockpiling has not yet shown up in import statistics because the ivory has been deliberately held in bonded warehouses so as not to appear in customs-cleared trade statistics. But international embarrassment will be unavoidable when the trade figures for August appear any day now, according to a well-informed source.

Japan imports almost half of the world's ivory. The industry is worth about ¥20,000 million ($140 million) a year and supports about 30,000 employees. Over half of the imports go into the manufacture of pencil-sized personal seals that can cost as much as ¥80,000 ($550) for a set of three. When the various ivory trade organizations pledged to show "self-restraint" in June, they also expressed their hope to continue their business no matter how "frugal" it might be.

The United States, European nations and several other countries have imposed total bans on ivory imports. And there are strong international pressures to impose a total import ban under the Convention on International Trade in Endangered Species (CITES) to which Japan is a party. A CITES meeting to vote on the issue will be held next month in Switzerland.

MITI said in July that while, "in principle", Japan favours a total ban, there are some countries (notably South Africa, Zimababwe and Botswana) that wish to continue trade on a sustainable basis and "it is not proper to disregard their intention and deprive them of economic resources unilaterally". Takimoto says MITI will decide on the length of its present temporary total import ban after next month's CITES meeting. But critics say the temporary ban is just a "cosmetic" measure for the meeting in Switzerland.

David Swinbanks

CHEMICAL WEAPONS

International forum backs ban

Canberra

A PROPOSED international ban on the production and stockpiling of chemical weapons could push up the worldwide price of chemicals by one-quarter per cent. According to Tom Reynolds, head of Australia's industry delegation to the international Government–Industry Against Chemical Weapons Conference held in Canberra last week, consumers would have to bear the $1,000 million cost to industry of the new treaty.

The ban received the unanimous support of representatives of 95 per cent of the world's chemical industry, including those from Iraq and Iran, which were accused of using chemical weapons during the Gulf War. The aim of the conference was to bring government and industry together to discuss the practicalities of an international ban on chemical weapons.

Much of the proliferation in chemical weapons seen in the past decade has been linked to the production of chemicals by private industry, without governmental control. The chemicals that provide precursors to those used in weapons have a wide range of civilian applications.

Chemical weapons have been on the agenda in the Geneva arms-control negotiations since 1968. In Paris earlier this year, 149 nations met for a conference on the prohibition of chemical weapon use.

Four hundred delegates from 60 countries, excluding Libya and Syria which chose not to attend, were present in Canberra. The Soviet Union and the United States are the only two countries to admit to having chemical weapons, although another 20 countries are believed to have the capability to produce them. The United States is the only country that admits to producing chemical weapons.

The conference agreed to the formation of an industry forum to lobby in Geneva for an early signing of a treaty. Signing is unlikely to take place before 1992, but there was general agreement that political and technical issues could be worked out by the end of 1990.

Important elements of the proposed treaty will be a combination of regular and impromptu inspections of each participating nation's chemical plants. Concern over commercial confidentiality was partially allayed by a call for amendments to the treaty protecting the confidential transfer of data between industry and the national governments of the inspectors. "This will give industry some confidence that their trade secrets won't suddenly come out in the public domain", said Reynolds.

Challenge inspections would be conducted by an agency similar to the International Atomic Energy Agency, a multilateral organization that inspects nuclear power plants worldwide. Such a secretariat would cost $100 million a year.

There was little agreement, however, on how to deal with countries that break the treaty. "In the end there is no international police force; if a country is determined to break its obligations, it can. If a signatory does not comply with the verification procedures outlined in the treaty, then it is no longer a party to it, and industry would suffer if it dealt with that country," said Michael Costello, delegation leader for Australia.

Both the Soviets and the Americans were eager to be the first to announce initiatives. The Soviets claimed to be the first to agree to the challenge inspections "anytime, anywhere". The US delegates countered with then-Vice President George Bush's 1984 speech urging impromptu inspections.

Nikita Smidovich, head of the Soviet arms control and disarmament section called the Americans "double-faced" because of their continued production of chemical weapons while advocating non-proliferation and an eventual ban. The United States ceased production of chemical weapons in 1969 and resumed in 1988, because its stockpile was no longer considered a credible deterrent to the Soviet Union, which did not cease production until 1987.

With the world's chemical industries opposing all "diversion of industry's products for the manufacture of chemical weapons", the US government may have to make its own chemicals to avoid forcing its industry to break the agreement. According to Kyle Olson, one of the US industry representatives, the Americans are getting at least some of their chemical-weapon products on the open market. The US ambassador to the Geneva weapons talks, Max Friedersdorf, said that as chemical weapons were being produced with congressional approval, the use of commercial products in chemical weapons did not constitute a "diversion of industry products."

Tania Ewing

---

for import of the latest foreign technology and, according to *Nikkei Biotechnology*, the Red Cross has already approached Baxter.

But in the United States, blood coagulants produced by the monoclonal-antibody technique are much more expensive than conventional coagulants and are beyond the reach of many haemophiliacs. Given the high price of blood plasma in Japan, it seems certain that the price of domestically produced coagulants will be high. Seizo Murakami, chairman of the blood business promotion council, says the council has "no idea" what the price of Red Cross coagulants will be.

Blood-product manufacturers refuse to comment on the report. But a representative of the Chemo-Sero-Therapeutic Research Institute (Kaketsuken), a manufacturer in Kyushu, at a press conference last year, complained bitterly that the Red Cross had made requests for transfer of its blood-product manufacturing technology. And, according to a reliable source, Kaketsuken is "furious" about the council's recommendations.

Mitsuru Miyata, editor of *Nikkei Biotechnology*, says that Japan's four blood-product manufacturers (Kaketsuken, Midori Juji, Fuji Rebio and Nihon Seiyaku) realize that blood products are unlikely to be profitable and are diversifying into new areas. But it seems unlikely that the Red Cross will be able to replace their expertise in research and development.

David Swinbanks

. . . and so does Bush

Washington

IN his first speech before the United Nations General Assembly last Monday, US President George Bush proposed steps towards a worldwide ban on the production and stockpiling of all chemical weapons. The proposal followed a successful weekend meeting in Jackson Hole, Wyoming, between Secretary of State James Baker and Soviet Foreign Minister Eduard Sheverdnadze, at which the United States and the Soviet Union agreed to provide information on their chemical-weapons arsenals and allow mutual inspection of storage sites.

Bush said that the United States is ready to destroy "98 per cent" of its chemical weapons stockpile in the first eight years of a new treaty, provided the Soviet Union joins the ban, and to destroy "every one" of its chemical weapons within ten years once all nations capable of producing chemical weapons sign the treaty.

A major new element of the proposal is the willingness of the United States to begin chemical weapons cuts before an international treaty is concluded. "The United States is ready to begin now", said Bush, and is prepared to eliminate "more than 80 per cent" of its chemical weapons before a treaty is signed, provided only that the Soviet Union reduces its stockpile to an equal level and there is agreement on the conditions, including inspection, under which stockpiles are to be destroyed.

The Bush proposal is partly seen as an attempt by the United States to regain the momentum lost to the Soviet Union in global arms-control negotiations. But the willingness of the United States to begin making cuts immediately is clearly intended to have a wider effect, pushing forward the 40-nation negotiations at Geneva on a chemical-weapons ban.

Alun Anderson

BRAZIL'S ELECTIONS

Candidates' science lessons

São Paulo

THE support of science and technology has not been a conspicuous topic in speeches by candidates in the Brazilian presidential election, due on 15 November. But several national institutions have submitted to the candidates a 45-point document reminding them of the importance of science to Brazil's development, and making suggestions for the future.

Although it is meant to be optimistic, the tone of the document gives a measure of the despair felt by the scientific community. It tells the candidates, for example, which government bodies deal with research funding, as if George Bush or Michael Dukakis had had to be told in last year's US election campaign what the National Science Foundation is and what it does.

The report comes from the federal government's Special Secretariat for Science and Technology, with the support of the Brazilian Academy of Science, the Council of Rectors of Brazilian Universities and the influential Federation of Industries of the State of São Paulo, the country's most industrialized state.

Notably absent from the signatories was the Brazilian Society for the Progress of Science (SBPC), the biggest association of scientists; its president, Ennio Candotti, said that even though he agrees with most of what the report says, it was not "politically convenient" to sign it, because of its governmental origins.

SBPC is unhappy with the present government's treatment of science. At the beginning of President José Sarney's term, a new Ministry for Science and Technology was created, and there was a promise to increase research and development spending to 2 per cent of gross national product (GNP). But with Sarney's term due to expire in March 1990, spending on research and development stands at only 0.7 per cent of GNP, and the Science and Technology Ministry has been replaced by the Special Secretariat for Science and Technology, a body with cabinet rank, but without the status of a ministry. But SBPC's criticisms are partially echoed in the document, which is why Candotti has not condemned it.

Thus the report admits some problems that scientists have been complaining of for years. Bureaucratic complexity in foreign currency exchange, along with laws restricting the import of items for which a Brazilian equivalent exists, have made it almost impossible to make use of foreign funds for research. Brazil is now negotiating the second phase of a World Bank loan that would provide $330 million for research, with an equal sum to be provided by the federal government, over the next five years. This would be an enormous boost for university research, but only if the money actually reaches scientists.

The suggestions in the document include new tax incentives for private companies investing in research and development, and better integration of university research with industry. This is a theme particularly dear to the secretary of science and technology, Décio Leal de Zagottis, former director of the Escola Politécnica, São Paulo's engineering school.

The initiative now rests with the presidential candidates. According to press reports, the leading candidate, Fernando Collor de Mello, plans to reduce the number of ministries from 23 to 10, but has apparently decided to retain the Special Secretariat for Science and Technology, rather than merging it with a bigger ministry. But Brazilian scientists will not lose sleep over the fate of a government department: what they fear most is Brazilian politicians' habit of dismantling the work of their predecessors, making empty any pretence of a long-term policy for research. **Ricardo Bonalume Neto**

Correction: German telescopes

There have been no funds set aside for the building of a large new telescope in West Germany, contrary to the first paragraph of an article in *Nature* last week (*Nature* **341**, 177, 1989). One of the telescope designers mentioned is Gerhard Schnur of the University of Bochum. □

INDIA

Restriction venture

New Delhi

INDIA has launched its first venture capital company to make restriction enzymes. Bangalore Genei Private Ltd has been set up by Dr P. S. Babu, a theoretical physicist-turned-molecular biologist, and Dr K. Prasad, an immunologist, both of whom have been associated with the Indian Institute of Science, Bangalore. A large part of the funding for the company comes from the Technology Development and Information Company of India.

The new company will obtain the know-how for the manufacture of the enzymes from Astra Research Centre, Bangalore, which carries out research in medical biotechnology and is developing diagnostic kits for a variety of tropical diseases. The Centre for Genetic Engineering will also assist the new company.

Restriction enzymes are currently being imported by individual laboratories and in bulk quantities by the CSIR Centre for Biochemicals, New Delhi. The new company will initially make the more important and commonly used restriction enzymes. K. S. Jayaraman

EUROPEAN SPACE AGENCY

Observation satellite flies first hurdle

Paris

DESPITE financial worries within the member states of the European Space Agency (ESA), the next-generation European remote-sensing satellite (ERS-2) last week survived an early round of discussion of its fate. There was concern within ESA that the satellite would have to be cancelled or postponed, as its major backers — Britain, France and West Germany — were rumoured to be unenthusiastic. The three nations are expected to provide about 65 per cent of the costs. But at the Earth Observation programme board meeting last week, member states supported a recommendation that the satellite programme should begin.

In the corridors of ESA, reactions to the news are restrained, as the go-ahead for ERS-2 (or EEMS — European environment monitoring satellite as it is known within ESA) now depends on the decision of the ESA council at its October or December meeting. And it is only then, if a decision to proceed is agreed, that member states will be asked to commit themselves to a budget.

The uncertainty over ERS-2 has nevertheless emphasized budget difficulties within ESA. Having committed themselves in November 1987 to the costly Columbus programme, the Hermes space shuttle and Ariane-5 launcher, member states have little money left for the optional 'user programmes', such as Earth observation, and microgravity research. France, having agreed to finance its own Spot remote-sensing programme to the end of the century (see *Nature* 340, 583; 1989), was expected to give ERS-2 only a lukewarm reception. Similarly, West Germany agreed only a third of the increase requested in next year's space budget (see *Nature* 340, 179; 1989), putting both ERS-2 and the data-relay satellite, DRS, under threat.

The US Landsat and French Spot remote-sensing satellites do not have the same goals or capabilites as ERS, whose synthetic aperture radar allows images to be collected at night and through cloud cover, while a radar altimeter measures peaks and troughs in the ocean surface to within a few centimetres. ERS-2 should cost "about 51 per cent" of the total costs of ERS-1, according to a discussion document, and is needed to provide data continuity between ERS-1, due for launch in October next year and the polar platform scheduled for 1997. If ERS-2 does not go ahead immediately, say sources within ESA, not only will this continuity be lost, but the satellite will become more difficult and expensive to build if existing teams disband. A novel global-ozone measuring experiment it is to carry will also be threatened.

ANTARCTIC SCIENCE

Women accept polar challenge

Munich

IGNORING the example set by the US Antarctic research station and others, West Germany has always refused to send women to spend the winter at its own Antarctic station. Nine all-male teams in a row have overwintered at the station.

This autumn, that will change, when nine women will make the long trip from Bremerhaven to the Georg-von-Neumayer-Station on the Ekström shelf ice. The women, trained in survival skills, have important scientific tasks to perform during their 320-day period of isolation from February to December 1990.

Frailty was not the problem for German women researchers eager for duty in the Antarctic. Gotthilf Hempel, director of the West German polar research institute in Bremerhaven, never wanted to send a mixed team because of the risk of pregnancy.

For years, the leader of the current expedition, Monika Puskeppeleit, was frustrated by this rule. Ever since finishing her medical degree at Heidelberg in 1984, she had been prodding Hempel to let her join the West German team. In 1987, when she was about to give up and ask the Australians if she could join their team, Hempel agreed to consider another solution — sending a women-only team. "I am a biologist and I believe in fecundity", explained Hempel. "A pregnancy in the isolation of the Antarctic can be fatal for both mother and child."

The Neumayer Station is equipped with a makeshift operating room for emergency procedures such as appendectomies. But help from the outside would be impossible during most of the winter, when temperatures reach −46 C°. Would Hempel not trust the researchers to avoid pregnancy in the Antarctic? "No", he said, "I do not trust [birth-control] procedures completely." Puskeppeleit and two geophysicists found two like-minded meteorologists and four technicians to complete the team. The team will measure seismic disturbances, as well as observing the Earth's magnetic field as part of the international project Intermagnet and collect data on the weather for global climate studies.

Puskeppeleit will gather data for a joint project with the German Aerospace Research Establishment (DLR). She will see if the bacterium *bacillus subtilis* is suitable as a "living sensor system" for measuring the effects of the seasonal stratospheric ozone deficiency in the Antarctic. Similar experiments with the bacterium have been carried out in space.

Unlike the larger US base at McMurdo, the German station is a temporary structure, consisting primarily of two large steel pipes. West Germany plans to invest in a permanent station to be built by the early 1990s. The German station is located at 70′37″ south latitude, 8′22″ west longitude off the Weddell Sea. The nearest other station belongs to South Africa and is 200 km away.

Hempel said that if he had reservations about sending the all-female team, "I would not have let them go". They are not going purely for the adventure of it or just to show off, he said. Instead, "they take it as a natural right" that women should have an equal opportunity.

Steven Dickman

The nine West German women due to leave for a 14-month stay in the Antarctic this autumn.

France asks for advice

Paris

FRANCE, which is to host a meeting of Antarctic Treaty signatories on 19 October, is looking at alternatives to ratification of the Wellington Convention on the Regulation of Antarctic Mineral Resource Activities (CRAMRA). With only a few weeks left before signatories to the treaty have to make up their minds, the Parliamentary Office of Evaluation of Technological and Scientific Choices was asked to give its advice and organized a 4-day series of hearings open to the press.

The parliamentary office was set up in July 1983 and consists of eight senators and eight deputies whose task is to advise parliament on the consequences of scientific and technological policies. Their decision to invite a string of experts — from marine biologist, Commander Jacques Cousteau, and the ecology group Greenpeace to senior civil servants and the head of the national petrochemical institute — to state their points of view in front of the press had no precedent.

CRAMRA aims to close a legal loophole in the existing treaty by limiting mineral exploration on the continent (see *Nature* 341, 93; 1989). Until the convention comes into force, all 16 signatories are bound by a moratorium on mineral exploration, which expires in November. So far, France and Australia have refused to ratify CRAMRA, saying that it will encourage, rather than simply limit, commercial exploration. Instead, they suggest that the Antarctic continent should be designated a world nature reserve, with only research activities authorized.

This position was last week endorsed by Remy Parmentier, of Greenpeace, and Cousteau, even though a ban on mineral exploration is unlikely to receive a unanimous vote by treaty signatories. The argument that the ban would be difficult to enforce, they say, also applies to the current moratorium. Lucien Montadert, director of the Institut Français du Pétrole, told the office that a search for oil in the Antarctic would not be technically feasible for 30 years, but added that, "if the possibility exists to look for oil, some day someone will look for it". Even if, for safety reasons, scientific geological surveys are carried out precisely where there is little likelihood of finding gas or oil, said Admiral Corbier, administrator of the French Antarctic Territories, the boundary between research and prospecting is often ill-defined.

Last Thursday, at the end of the session of expert testimony, it seemed likely that the office would recommend that France adopt a compromise position. Instead of ratifying CRAMRA, France will probably call for the existing moratorium to be extended until a competent authority is found to administer the Antarctic as a world nature reserve.

AGRICULTURE

Time for another change

Washington

US and world agriculture is ready for its third major change this century acccording to a report released by the US National Research Council, the research arm of the National Academy of Sciences. After the mechanization of agriculture, which began early in the century, and the introduction of chemical fertilizers, pesticides and high-yielding crop varieties which produced the 'green revolution' of the 1960s, will come 'alternative' farming that uses skilful management to take advantage of the biological relationships that occur naturally on the farm.

Alternative Agriculture is a 450-page report produced by a committee of 17 researchers from 11 US universities and is based on detailed studies of 14 US farms where alternative farming practices were being tried out. Although the title of the report suggests an association with the 'alternative society' of the 1960s, the report makes plain that "the hallmark of an alternative farming approach is not the conventional practices it rejects but the innovative practices it includes".

The overall objective is said to be to enhance and sustain useful biological relations rather than to reduce and simplify them through conventional monocultures and blanket application of pesticides and herbicides. As examples of the alternative approach the report notes:

- Genetic improvement of crops to resist pests diseases and drought, and to use nutrients more effectively.
- The planting of a diversity of crops rather than a single one. Crop rotation can reduce problems from weeds, disease and pests and cut fertilzer use and soil erosion.
- Reliance on the prevention of disease in animals rather than frequent use of antibiotics.
- Integrated pest control methods.

Integrated pest control uses ecological principles to capitalize on natural pest mortality, predator–prey relations, genetic resistance and the effect of the precise

timing of tilling, cropping, pruning and pesticide application. Typically, integrated pest management requires fields to be 'scouted' to determine pest and disease levels before deciding what form of minimal intervention is best. The overall effect can be to reduce pesticide use and to make the farm more productive.

John Pesek, chairman of the NRC committee and head of the department of agronomy at Iowa State University, argues that alternative agriculture is economically successful chiefly because it reduces the cost of "off-farm inputs" such as fertilizers and pesticides, while maintaining productivity.

"Successful alternative farmers do what all good managers do. They apply management skills and information to reduce costs and improve efficiency while maintaining yield levels", he says.

The report's good news is that alternative methods work and through reduced pesticide use and better soil management, could help to ameliorate conventional agriculture's problems — 3,000 million tons of topsoil erode from US farms each year, and pesticides and fertilizers in agricultural run-off, when added to the silt, are major causes of water pollution. But the bad news is that federal farming programmes make it very difficult to deviate from conventional farming practices. Seventy per cent of US cropland is covered by commodity programmes designed to shield farmers from fluctuating prices. One effect is that any practice that reduces acreage planted to a programme crop reduces the acreage eligible for subsidies for the next five years. Thus, if a farmer switches from corn to alfalfa for one year to increase nitrogen in the soil, he will incur an extended loss of subsidies.

Commodity programmes also base future payments on past production. While this system has helped to push up US agricultural production, it has also encouraged farmers to cultivate marginally productive land and to use levels of fertilizer and pesticide that would make little sense without incentives. The result, the report says, is that many farmers simply aim to "maximize present and future program benefits".

Other programmes encourage massive use of pesticides by setting cosmetic standards for fruit that have little bearing on nutritional quality. Tolerance of minor surface blemishes would permit major reductions in pesticide use.

The committee recommends that federal commodity programmes, which cost $14,000 million a year, be restructured "to help farmers realize the full benefits of the productivity gains possible through many alternative practices". At a minimum, the programmes should be changed to encourage crop rotation.

The US Department of Agriculture (USDA) has generally welcomed the report and accepted that change is needed. But the challenge will be to provide farmers with the much higher level of training and information they need to adopt new practices. That help is not available from traditional sources such as USDA, extension agents or agricultural supply dealers. The report calls for a new $40 million competitive grants programme for alternative agriculture research, along with increased funds for demonstration and implementation of the research results.

Pesek says he cannot predict the precise economic effects of the widespread use of alternative agriculture. But he says the committee is convinced the methods work, and that they would produce an ample food supply while reducing environmental problems. The potential benefits, he says, are "too attractive to continue to lie fallow". **Alun Anderson**

BIOTECHNOLOGY LICENSING

EC announces bovine hormone moratorium

Munich

In the middle of this month, European Agriculture Commissioner Ray McSharry made the long-expected announcement of a 15-month moratorium on the use of the genetically engineered hormone bovine somatotropin (BST). The moratorium is to allow for further study of the product. McSharry had been expected to propose a ban in August, but the Commission of the European Communities (EC) shied away in the face of pressure from the United States (see *Nature* 340, 415; 1989).

The moratorium (which the EC prefers to call a "period of evaluation") must still be approved by the Council of Ministers, which will meet soon to discuss the matter. The European Parliament has also been asked to comment. The commission will issue a report based on the studies by October, 1990. A decision on licensing is expected to follow.

Clayton Yuetter, the US Secretary of Agriculture, has backed away from the threatening position he took in July when the moratorium was first discussed. He said he accepted the EC proposal as long as it was linked to scientific studies. But "a delay of 20 years" would not meet that criterion, he said.

US and EC officials are struggling to avoid a trade war over BST, which is expected to set a precedent for the licensing of other biotechnology products in Europe. Yuetter said that if the EC wants to reject BST on grounds other than efficacy, safety and quality — for example on economic grounds — then it should say so in the GATT international trade negotiations.

Steven Dickman

PhDs and the ESRC

SIR—Good graduate students publish — and the earlier they do so the better for science and themselves. Yet one public body in Britain, the Economic and Social Research Council (ESRC) has a policy which in effect prevents this.

The ESRC will not fund postgraduate studentships for academic departments where 60 per cent of PhDs are not completed within three years. (A year's grace is allowed for examiners to read the thesis and to arrange to meet.) The threat of blacklisting puts departments under strong pressure to discourage graduate students from publishing lest this delay them in finishing their theses.

In its evaluation, ESRC take account of all PhDs done in a department, so that its policy affects students who are self-financed or supported by other research councils The policy is justified on grounds of increasing "productivity" of post-graduate education, but there is no evidence that its policy will increase the production of better scientists. Indeed, in its search for an adminstratively recognizable measure of the efficient use of resources, ESRC's policy may have the opposite effect. Creative scientists will be penalized in two ways. First, activities unrelated to PhD work, however important to later work, will tend now to be seen negatively

Second, individuals showing traits of individuality and nonconformity at their interviews may be judged unlikely to complete in three years and so be denied admission

Peer review

SIR—Heartened by the recent comments on the role of journals in science (*Nature* **339,** 657, 1989) and on anonymous peer review (*Nature* **340,** 424; 1989) I would like to add the following points. They are not intended to be generalizations without exception, rather their validity depends on individual manuscripts

The editor should check that the comments of the reviewers are based on a thorough examination of the manuscript This is reasonable because the decision to publish rests solely with the editor and presumably is based largely on the reviewers' comments. Furthermore, the authors of the submitted manuscript should be informed of the reasoning behind the editor's decision, including which of the reviewers' comments were agreed or disagreed with and the relative importance given to these assessments. This will enable the authors of the manuscript to judge whether the editor's decision to accept or reject has been based on an acceptable level of knowledge of the results and understanding of the interpretations.

Should there be any statements in a manuscript supported by 'data not shown'? Would it not be better for the excess data to be placed in an appendix which is subject to review and, after publication, available on request?

Although reviewers have a selfless, charitable and onerous task, they receive in return knowledge of results, techniques and concepts well in advance of others. To a reviewer who is a competitor of the manuscript's authors, this can be a very big advantage over the other, less privileged, competitors. This is particularly true for reviewers who are in charge or part of large groups.

PO Box No. 123,
Lincoln's Inn Fields,
London WC2A 3PX, UK

SIR—One step towards a solution of the problem of peer reviews is for referees to volunteer their identities to authors Surely any referees who feel they are being fair-minded and objective have nothing to fear from such a disclosure?

Another step might be for manuscripts to be sent to a first referee for comment, then for the first referee's remarks as well as the manuscript to be sent to a second referee. In this way, the second referee would make a judgement not only of the manuscript but also of the first referee's comments

AIDS in Bulgaria

SIR—A recent article in *Nature* discussed the necessity of Bulgaria's mandatory programme for identifying people seropositive for the human immunodeficiency virus (HIV)[1] So far, more than two million people have been tested in Bulgaria, including so-called 'high-risk' groups (homosexuals, prostitutes, citizens who have spent time abroad and foreigners, including students who are long-term residents), as well as members of the general population aged 16–65 years.

To determine previous exposure to HIV, individuals are screened with an enzyme immunosorbent assay (EIA), and reactive samples are confirmed by the Western blot (immunoblot) procedure Confirmed positive results usually indicate the presence of virus in the body. On the other hand, negative results by EIA do not necessarily indicate the absence of HIV-1 infection, as virus can be isolated and proviral sequences detected in infected individuals who remain seronegative for prolonged periods[2,3]. By 7 July 1989, 77 Bulgarian citizens and 72 foreigners, 59 of whom were students, chiefly from Africa, were reported to be seropositive for anti-HIV by EIA (data supplied by Ministry of Health, Sofia). The seropositive students were sent home. Of the 77 EIA-positive samples from Bulgarian nationals, 53 were classified as indeterminant by Western blot[4]. Current experience indicates that virus will not be recovered from these people. So far in Bulgaria, only three people have been reported to the World Health Organization as definite AIDS cases[5].

Mandatory serological testing is not unique to Bulgaria For example, in Illinois, where mandatory premarital testing of 70,846 applicants for marriage licences was enforced, eight seropositives were obtained at a cost of $312,000 per identified individual[6]. The screening data from Bulgaria, revealing 1 2 confirmed seropositives per 100,000 Bulgarian nationals, indicate that HIV is confined chiefly to certain high-risk groups. It is noteworthy that the three specimens positive for virus were from members of such groups. The overall results are most encouraging from a public health point of view and suggest that there should be a reevaluation of the mandatory programme. In arriving at a decision, financial considerations must be weighed against possible benefits.

It would be desirable, particularly for countries such as Bulgaria where the HIV epidemic is at a very early stage, to have international reference laboratories to turn to in order to verify the presence of HIV-1 by isolation or by determination of proviral sequences.

Sunset for dangerous chemicals

SIR—Work on existing chemicals that are dangerous to man and/or the environment tends to focus on one issue at a time, at present chlorofluorocarbons (CFCs). For many years, polychlorinated biphenyls have been given the same intense attention. Plans to phase out these chemicals are under way. But such plans take a long time to develop, are very resource-demanding and may lead to development of alternatives that pose other threats.

In my view, however, the number of chemicals that need to be phased out is too large to allow time to proceed case by case. My suggestion is that we try to establish a process, nationally or, preferably within some international organization, such as the Organisation for Economic Development (OECD), whereby chemicals that need to be phased out (sunset chemicals), are identified according to generally accepted criteria.

The procedure might be as follows.

(1) Identify, according to set criteria, a number of chemicals (say 50 or 100) that should be phased out.

As a basis, lists of 'priority' chemicals, or of chemicals with specific hazardous properties — carcinogenic, mutagenic, teratogenic or hazardous to the environment — could be used. Criteria should be established whereby 'multiproblem' chemicals are distinguished. Step 1 would involve setting-up expert committees to develop criteria and the chemicals to be selected.

(2) Advertise the list, giving a proposed date for the phasing out of each chemical. At this stage, industry must be allowed to argue why a certain chemical should not be phased out. In Sweden this means that industry has to prove beyond reasonable doubt that the chemical in question is not a candidate for a sunset list.

(3) Once the list has been agreed to, nationally and/or internationally, companies could be obliged to report annually on the development of the phase-out. There should be a rule that no company must report a figure similar to or higher than that of the year before.

It is important to stress the quantitative aspect of the process because these are chemicals we want to get rid of. Companies may of course also report on protective measures, but this must not confuse the goal. The Swedish experience, for example with the Halving of Pesticides Programme, shows that such quantitative goals promote incentive and ingenuity.

(4) Results should be published regularly. On a national level, companies could compete, for example, for the title 'Company of the year'.

(5) The process should end with a ban, the sunset. Such a ban should be inherent in the process from the start. Responsible companies will have developed alternatives or closed processes, while less responsible companies will be punished for not having done so. Discussions and agreements between governments and industry will be a normal part of the process.

Such a process may be started at a national level and implemented by national legislation and regulation. As most chemicals move extensively in international trade and thus appear in, for example, many OECD member countries, the process needs to be internationalized. And a common understanding of the process within the international community would be an important step towards greater co-operation and harmonization between countries. The OECD could set an example to the rest of the world and take a strong lead on the road to a sustainable future.

Academic boycotts

SIR—Distinguishing academic from sports boycotts of South Africa ("Academics, cricket and apartheid" *Nature* **340**, 413; 1989) does seem appropriate in the light of the vital need for Great Britain and other nations steadfastly to support the academic institutions in South Africa that will be so essential in buttressing a post-apartheid society. In modern history, universities have generally outlasted the institutions of government, but that trend is likely to continue only if international support for a university's programmes is maintained in all but the most extraordinary circumstances, such as those now existing in China, where such support requires a degree of cooperation with the home government that is squarely inconsistent with the home government's actions against university welfare. Even in the case of China, international support should be eagerly reinstated as soon as conditions become acceptable, because, as with South Africa, the ability of the nation to make a transition toward a more open society depends, in part, on the vitality of the university. The university, much like the church, should be boycotted only when the institution itself cannot serve its universal mission under government stricture. A foreign government's displeasure can, in most situations, be conveyed by less injurious means.

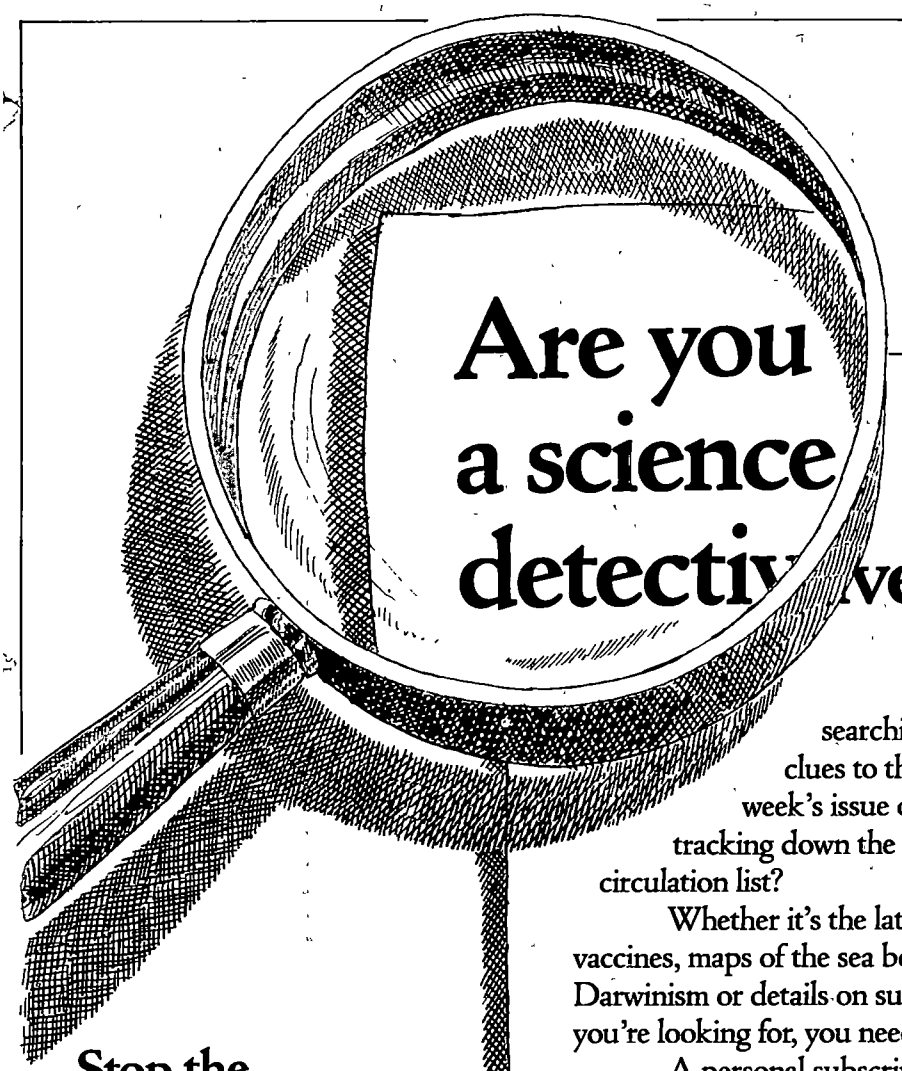
Journal costs

SIR—My mail this morning contained no fewer than half-a-dozen announcements of journals to which my poverty-stricken library was invited to subscribe. In every single case, the subscription costs quoted included both an 'individual rate', and an 'institutional rate' of anything up to twice as much. As medical staff in this country have received pay awards at least in line with official inflation figures, whereas my library budget has remained the same for the past three years, this seems unfair and ultimately self-defeating.



The problem lies in the fact that the production of new journals is, on the whole, supply-led rather than demand-led. Scientists are not so eager to learn of new developments in their specialized sub-fields as to be willing to put their hands in their pockets and pay for the knowledge contained in new journals. Rather, it seems to be the case that scientists are well aware that appointment, tenure, promotion and grant-awarding go by the number of papers published, and so are keen to find new outlets to publish in. I have heard rumours of one who boasted of having managed to publish 16 papers based on the same set of data. Although this is, I hope, an extreme case, it is undoubtedly common to find that several parts of what is clearly the same study have been published, under different permutations of authors' names, in different journals, thus making it impossible for an individual with a personal subscription to one relevant journal to cover the study adequately.

The solution seems to me to be to find some other way of selecting candidates for appointment, tenure and so on. Surely the best and brightest minds of the scientific world, currently fully engaged in making sure that their names are somewhere in the list of authors of anything their graduate students publish, could find some better method of assessing each other? If the only scientific papers published were those needed to inform other scientists of new developments, a considerable proportion of these new journals would die of inanition.

If your own publication, Sir, was genuinely devoted to maximizing the distribution of scientific information, I am sure that you would admit that handling institutional subscriptions is less work for you than handling individual subscriptions, and would be offering institutional subscriptions at half the price of those of individuals, rather than the other way round.

MOLECULAR AND CELLULAR NEUROSCIENCES

Editor

P. MICHAEL CONN
The University of Iowa, College of Medicine Iowa City

Molecular and Cellular Neurosciences publishes manuscripts describing novel and original results in the areas of molecular neurobiology, neuropharmacology, neuroendocrinology, neurochemistry, and neuroanatomy (at the molecular, cellular, and tissue levels). Studies may be performed in animal and human model systems so long as the fundamental observations relate to basic science (as contrasted with clinical science).

Volume 1 (1990), 3 issues ISSN 1044-7431

Making good databanks better

Like motherhood before Green considerations made it unfashionable, the scientific community's databanks enjoy the presumption of virtue. But there remain important problems to be solved.

It is splendid, and entirely consonant with the doctrine that the scientific enterprise is a communal enterprise, that data arising in the course of discovery should be generally available. Access is especially important when a claim can be checked only by reference to the original data, but it must often be that data gathered from several investigators is more valuable in a common databank than if separate parcels remain where they arise

So why does *Nature* not make it a precondition of publication that experimental data should be submitted to the appropriate databank? The question is more often asked as databanks proliferate, and as compliance with the pleadings of the databanks becomes more common. What follows is an explanation both of this journal's continued caution and of why that diffidence does not imply dissent from the objectives of the databanks.

The sheer number of databanks now extant is part of any explanation. The days have gone when the Crystallographic Data Centre at the University of Cambridge, created in the 1930s by the International Union of Crystallography, was the chief organization of its kind, but that has been the model for several more recent creations, notably the nucelotide sequence databanks operated in concert at the European Molecular Biology Laboratory (EMBL), Heidelberg, the Los Alamos National Laboratory and at the Riken Laboratory at Tokyo in Japan. Now, largely on the initiative of Dr Fred Roberts at Yale University, an international network (centred on the Brookhaven National Laboratory) is also being formed to collect three-dimensional structure data on proteins and other structures.

Such databanks function on common principles. The submission of data is voluntary, but access is general. Organization is often a formidable undertaking, as the nucleotide sequence databanks have discovered in the past five years. Compilations of data are available to all, usually at the modest cost of the magnetic tape or compact disk that carries them. They are a considerable public service.

Other databanks function differently. Part of the legacy of international projects such as the International Geophysical Year is the network of data repositories scattered about the globe, while particular Earth satellites have led to the creation of their own data repositories whose value persists — data from the Einstein X-ray satellite, launched more than a decade ago, are still being used, for example (see page 309, this issue). Cores drilled in the ocean floor are similarly available, while it is intended that data collected by the Hubble Space Telescope will be open to all once the principal investigators have had a crack at them. These are sensible ways of making information generally available, but because these databanks are created by the voluntary acts of single projects, they pose no difficulties for researchers or for journals.

Problems of principle do arise when success rests on the willingness of individual researchers to submit their data. This is the case with the internationally integrated nucleotide sequence databank — but nothing in what follows implies that the objectives of that enterprise are anything but excellent.

One difficulty is geographical As things are, the three collaborating centres have divided the world between them, preferably taking in data electronically from individual researchers, but otherwise undertaking to type in manually data appearing in journals. Access to this databank will soon be possible by computer. One obvious difficulty is that access is patchy. People in, say, India have less easy access than those elsewhere, and may feel doubly injured by demands that the contribution of their data to the common pool from which others will benefit most should be a precondition of publication.

The Soviet Union is in worse shape; the Soviet Academy of Sciences buys an updating tape from Heidelberg each month, but has been told that it cannot be a full partner in the collaboration for many different reasons — that full membership would entail information about the operation of computers covered by the strategic embargo, that three partners are a sufficient headache for the time being and that, in any case, the Soviet Union does not produce many nucleotide sequences. Even allowing that the task of accumulating sequences is herculean, an enterprise that seeks to be international and comprehensive could have spent more time worrying about equality of access.

Commercial difficulties also arise. Academic researchers may regard submission as the rule, but those working for commercial organizations will be more restrained. Sequences published *in extenso* will be available, but what about the rest? Commercial organizations are notoriously unwilling to let their competitors know what interests them, and may legitimately claim the right to secrecy while enjoying free access to what academics publish. That is why the databanks have been reduced to pleading with commercial companies at least to keep their sequences securely.

Still more worrying is the commercial use of nucleotide sequence data. Already there are several small companies selling packages of proprietary interpretive software together with the contents of the databanks. It is not difficult to think that there will soon be consultancy firms offering to interpret the contents of the databanks for the benefit of commercial clients. The development of such services shows a need for them, but their equitability as it affects the providers of the data and even the databanks themselves has been inadequately explored.

The three-dimensional structure databank raises another difficulty. The case for it is strong: the publication of a molecule's structure may be useless to others without more detail, atomic coordinates for example. But it may be easier (and quicker) to reach broad conclusions than to refine the atomic coordinates, making them unambiguous. So authors will enjoy a moratorium between publication and the submission of data that will no doubt also ensure that no "sharpshooting theorist" (one researcher's phrase) is the first to interpret the structure.

The moral for journals such as this is plain. Their first duty is to speed the process of publication but also to ensure (as far as possible) the integrity of what they publish, which gives them a right to ask for supporting data (sequences, atomic coordinates) even when they have no space to publish them. They should do that more often, and should also arrange to provide access to them. But journals have no right to adjudicate upon a contributor's subsequent conduct — and have few sanctions, anyway. If there must be policemen, grant-making agencies are better placed. But there is a prior need — that the unanswered questions of access and equity should be tackled energetically by some body such as the International Council of Scientific Unions. Meanwhile, *Nature* will continue to urge on its contributors the importance of submitting their data to the databanks, but will not exact unenforceable promises to do so.

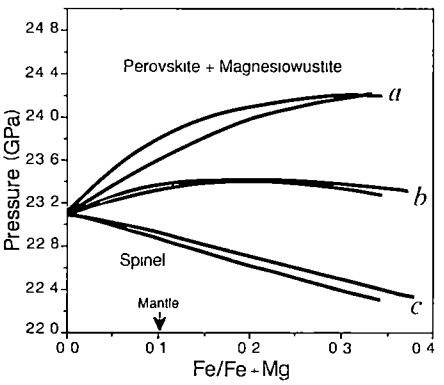
MANTLE GEOPHYSICS

Mineralogical phase change at the 670-km discontinuity



Bernard J. Wood

THE boundary between the upper and lower portions of the Earth's mantle is generally taken to correspond to the worldwide seismic discontinuity at 670 km depth, at which the seismic-wave velocity increases by a few per cent[1] and the density of the silicate minerals increases. The simplest explanation, that the discontinuity is due to an isochemical phase transformation in a mantle of uniform composition, is disputed in the light of incompatible experimental data[2] on the thermodynamic and elastic properties of high pressure phases. An alternative model is that the mantle is chemically stratified with at least one major compositional discontinuity at 670 km and possibly other distinct layers at shallower depths[3]. But in a new experimental study[4], Ito and Takahashi show that an isochemical transformation in $(Mg,Fe)_2SiO_4$, the dominant component of the upper mantle, has many of the properties required to explain the 670-km discontinuity. Their results would thus be consistent with both upper and lower parts of the mantle being peridotitic in composition.

The question of whether the mantle, which is convecting vigorously, is chemically layered is crucial to understanding its dynamics and its chemical and physical history. Numerical simulations[5] indicate that even small compositional differences, equivalent to a 3-per-cent change in density, would be sufficient to inhibit convective exchange between the upper and lower mantle and hence to isolate the lower mantle from most plate-tectonic processes. Many geochemists have argued that such isolation occurs, on the grounds that it explains the apparent depletion of the source region of oceanic basalts in lithophile elements such as K, Rb, Cs, U and Th relative to the inferred composition of the bulk Earth. Modelling[6] of the isotopic evolution of this source region implies that it corresponds to about 30 per cent of the volume of the mantle, which happens to equal the volume of the mantle above 670 km.

Seismologically, the 670-km discontinuity is extremely sharp, giving rise to underside primary-wave reflections that require[7] the velocity increase to take place over a depth interval of less than 4 km. Isochemical transformations in complex systems are generally continuous and spread out, however, implying that they cannot, in general, give rise to reflections at the wavelengths of concern. Chemical stratification, on the other hand, would give a true discontinuity.

The experiments of Ito and Takahashi[4] relate to the conditions under which $(Mg,Fe)_2SiO_4$ in the spinel structure transforms isochemically to $(Mg,Fe)SiO_3$ perovskite plus (Mg,Fe)O magnesiowustite at high pressures. The authors show that the transformation is extremely sharp for compositions with upper-mantle ratios of $Fe^{2+}/(Fe^{2+}+Mg)$ of about 0.1 and that it takes place under pressure conditions—23 gigapascal (GPa) at 1,600 °C—that closely approximate those present at the 670-km discontinuity. For these low iron contents, the experimental data indicate that there exists a narrow transition interval of coexistence of high- and low-pressure phases and that the transformation pressure may either increase slightly or decrease as Fe is substituted for Mg (see figure). But even if we assume large uncertainties in the partitioning of Fe and Mg between low- and high-pressure phases, it is virtually impossible to generate an interval wider than 0.2 GPa (6-km depth interval) and values less than 0.05 GPa (1.5 km) are most likely. This leads to the unexpected conclusion that the isochemical transformation of $(Mg,Fe)_2SiO_4$ spinel to perovskite plus oxide is essentially discontinuous and is thus capable of acting as a seismic-wave reflector.

The breakdown of $(Mg,Fe)_2SiO_4$ spinel to perovskite and magnesiowustite at 1,600 °C (after ref. 4). Note that the transition interval of coexistence of all three phases has a maximum width of 0.2 GPa (6 km) if we use possible geometry *a*. The most likely geometries, however, are *b* or *c* which give extremely narrow transition intervals for upper-mantle values of $Fe^{2+}/(Fe^{2+}+Mg)$.

The phase transformation may exhibit one of the main features of the 670-km discontinuity, but is it consistent with other geophysical and geochemical data? Jeanloz and Knittle argue in another new paper[8] that the density of the lower mantle (known to an accuracy of about 0.5 per cent) is too high for it to be compositionally equivalent to upper mantle peridotite. From their measurements of the compressibility and thermal expansion of the perovskite phase, they infer that the lower mantle is enriched in iron relative to the upper mantle and hence, by implication, that the 670-km discontinuity corresponds to both a chemical boundary and a phase transformation. This argument depends, however, on measurements of the thermal expansion of perovskite at low pressure, well outside the perovskite stability field[2], that gave a high coefficient of thermal expansion. There is doubt about the applicability of these data, collected on a metastable phase and requiring much extrapolation in pressure and temperature, because measurements of other perovskite-like phases[9] yield lower thermal expansions. Adoption of a smaller thermal expansion coefficient brings the density of lower mantle into approximate agreement with that expected for peridotite compositions (C.R. Bina and P.G. Silver, personal communciation).

Although geochemical data clearly show long-term segregation of the mantle into regions distinct in isotope and trace-element evolution, there is no requirement that these reservoirs exhibit gross differences in major-element composition or that they be radially distributed above and below 670 km depth. Furthermore, there is increasing seismological evidence that, at plate boundaries, subducting slabs penetrate into the lower mantle[10], implying that there must be at least limited chemical interchange across the 670-km discontinuity. Although chemical stratification at 670 km provides a convenient explanation for the isotope data, mixing of the upper and lower mantle would also be inhibited, but not completely stopped, by a phase transition with a slightly negative pressure–temperature dependence. The transformation studied by Ito and Takahashi fulfils this requirement. Thus the new experimental data indicate that a simple phase change explains the discontinuity. Measurements of the density of perovskite plus magnesiowustite under actual lower-mantle conditions are required to refute or confirm this. □

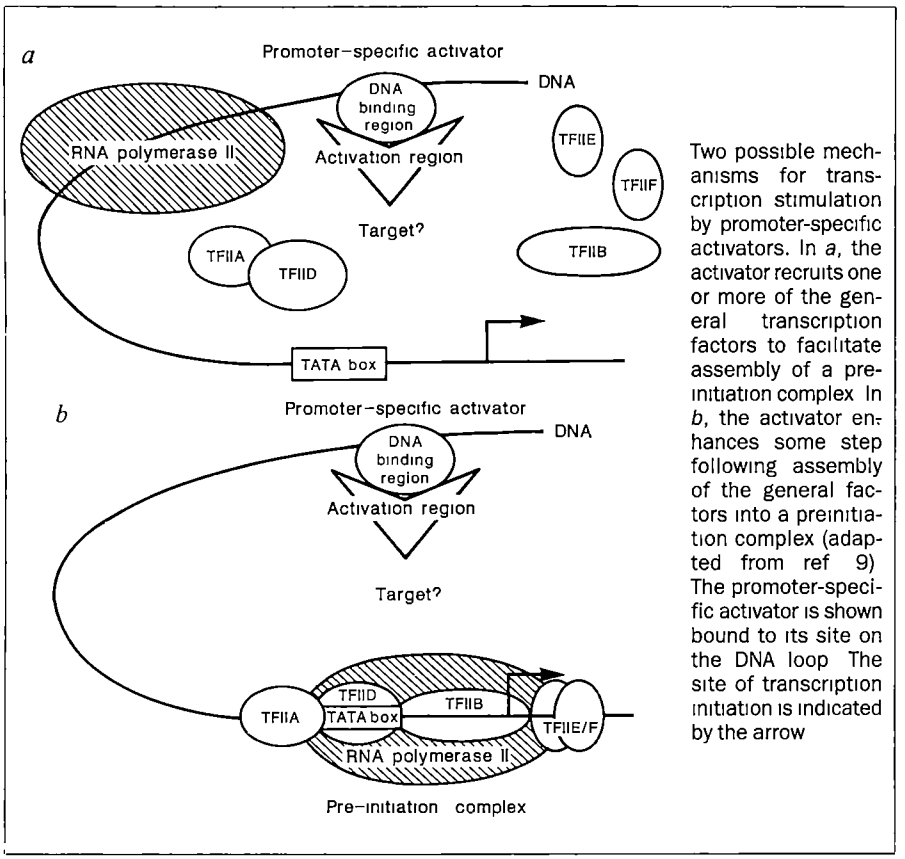
GENE TRANSCRIPTION

Activator's target in sight



James W. Lillie and Michael R. Green

ALTHOUGH accurate transcription of a eukaryotic protein-coding gene was first reconstituted in a cellular extract ten years ago[1,2], we do not yet know what the components of these extracts are nor how they are regulated. In the interim, we have stockpiled the genes of many promoter-specific activators, which augment the transcription of particular genes, and several subunits of RNA polymerase II, the enzyme that transcribes all protein-coding genes. But most basic components of the transcription machinery remain elusive. It is therefore exciting that two genes encoding basic transcription factors have been cloned as reported in refs 3–6 and on page 299 of this issue[7], and that the cloning of other general components seems at hand. Once these basic factors are identified, we may better ask how transcription is regulated.

Crude extracts of mammalian cells have been broken into at least five fractions (originally TFIIA through TFIIE) that are required by RNA polymerase II for the accurate transcription of a DNA template (reviewed in ref. 8). As TFIIC has become a relic and the original TFIIE has been split into IIE and IIF, we are left with TFIIA, IIB, IID, IIE and IIF. But what are these factors and how do they work? We do not know how many polypeptides comprise each factor nor which of the polypeptides are normally associated with one another in the cell. Have natural complexes been disrupted by chromatography and do other, unrelated proteins remain unseparated?

Progress has been slowed by the difficulty in obtaining a pure, concentrated supply of each factor. The purification of mammalian transcription factors is expensive and arduous. To make matters worse, the least abundant and most labile factor — TFIID — is required for the first step leading to transcription initiation (see ref. 9). Without TFIID, no transcription event can be studied. For this reason, the discovery that yeast contain a readily purified substitute for the mammalian TFIID fraction was a major breakthrough[10–12]. It then became feasible to sequence a piece of the purified protein and construct a probe to clone the gene[4,5,7]. Meanwhile, the *in vivo* experiments required to authenticate the cloned gene had been completed independently. Yeast geneticists, also working to identify genes encoding basic transcription factors, simultaneously identified this locus as one important for regulating transcription[3].

In a separate development, biochemists working to identify proteins that stick to RNA polymerase II, cloned a gene encoding another basic factor, RAP30, a subunit of the TFIIF fraction[6]. RAP30 comes bound tightly to another polypeptide, forming a heteromeric complex called RAP30/74 (ref. 13). This complex is required for the final stages of transcription initiation and for chain elongation. Besides binding tightly to RNA polymerase II, RAP30/74 is an ATP-dependent DNA helicase[6].

Two possible mechanisms for transcription stimulation by promoter-specific activators. In *a*, the activator recruits one or more of the general transcription factors to facilitate assembly of a preinitiation complex. In *b*, the activator enhances some step following assembly of the general factors into a preinitiation complex (adapted from ref. 9). The promoter-specific activator is shown bound to its site on the DNA loop. The site of transcription initiation is indicated by the arrow.

Sigma homologue?

It is the implicit hope of all gene cloners that the amino-acid sequence deduced from the gene sequence will provide a clue to how the protein works. The cloners of both TFIID and RAP30 claim their protein is similar in sequence to bacterial sigma factor[6,7]. Sigma, the most loosely associated component of bacterial RNA polymerase, is required for accurate initiation of transcription. There has been much speculation that one of the eukaryotic transcription factors is the sigma homologue. Although TFIID and RAP30 cannot both be *the* sigma homologue, perhaps each represents one portion of sigma.

The diverse activities of sigma, which include RNA polymerase binding, promoter recognition and DNA melting (see ref. 14) may be distributed among several eukaryotic factors. If so, it would seem reasonable that TFIID, which recognizes the TATA box, an AT-rich sequence upstream of the start site of transcription, has homology to a sigma region that is thought to contact the TATA-like sequence (−10) of prokaryotic promoters[7]. And it would not be surprising if RAP30, which binds to RNA polymerase II, is similar to a sigma region believed to bind bacterial RNA polymerase[6]. To extend the analogy, we may find that RAP74, the other subunit of TFIIF and a probable ATP-dependent helicase, is similar to the region of sigma posited to melt the DNA base pairs spanning the transcription initiation site[6]. In this light, we note a precedent for a fragmented sigma factor: a bacteriophage SPO1 sigma factor is composed of two proteins (see ref. 14).

Multiple TFIIDs?

Prokaryotes have multiple sigma factors, and different sigma factors direct RNA polymerase to different promoters[14]; do eukaryotes have more than one TFIID? Among eukaryotic promoters there is a wide spectrum of TATA-box sequences, and some promoters appear entirely to lack a TATA box. But as purified TFIID, from either mammalian cells[15,16] or yeast[17], binds to and acts upon all promoters tested, the existence of different TATA sequences may not necessitate multiple TFIID factors. Similarly, the widespread notion of 'TATA-less' promoters may be incorrect. At the very least, the cloned TFIID is the predominent TATA box

binding protein of yeast: all laboratories have cloned the same yeast gene and none has detected a related sequence or TATA-binding activity.

There are, however, two promoters that may have no requirement for TFIID: the yeast HIS4 T_c[18] and the mammalian U2 snRNA[19] promoters. These two promoters lack a canonical TATA box, and, in contrast to most genes, they are neither activated nor repressed by typical promoter-specific activators. Perhaps these promoters lack the target of the activator. Is the target TFIID?

Promoter-specific activators

Transcription by basic transcription factors is augmented by promoter-specific activators. These bind to short specific sequences within the vicinity of the gene. Genes encoding yeast activators have been cloned by classical genetics; but the strategies used to clone the genes encoding mammalian activators take advantage of the activator's affinity for a specific DNA sequence. In addition to the DNA-binding domain, activators contain an 'activating region', which is required for transcriptional activity (reviewed in ref. 20). Its name is testimony to how little we know of its structure or function. The sequence of an activator is of little help in deducing the position of the activating region; so far, activating regions are characterized primarily by a preponderence of a particular amino acid (for example, glutamine or proline, or acidic amino acids in general; see refs 20 and 21).

Activators enhance one or more steps leading to transcription initiation or elongation. Presumably this is due to direct interaction between the activating regions of these proteins and some component of the basic transcription machinery. General transcription factors interact with the promoter in a step-wise fashion to form a preinitiation complex (a cartoon of which is shown in the figure). In principle, any rate-limiting step in this assembly could be regulated by activators. One potential rate-limiting step is binding of TFIID (or a complex of proteins including TFIID) to the TATA box, the first step in complex formation.

Several lines of evidence suggest that TFIID is the target of the activator. A viral activator, the pseudorabies virus immediate–early protein, facilitates TFIID–promoter interactions: preincubation of the DNA template with purified TFIID obviates the need for the viral activator[22]. Also, TFIID affects the off-rate of a cellular activator, USF[23]. In addition, two cellular activators, mammalian ATF and yeast GAL4, alter the DNase I footprint of partially purified mammalian TFIID and increase protection over the TATA box[24,25]. Although these experiments are suggestive, there is no direct evidence linking the interaction of an activating region and TFIID to transcription activation.

Interactions between highly purified yeast TFIID and the activator Sp1 have not been detected[26]. This does not necessarily contradict the GAL4 and ATF studies, as the target of the Sp1's glutamine-rich activating region may be different from that of GAL4 and ATF. Comparison of these studies is further complicated by the different preparations of TFIID used The purified yeast TATA-binding activity of the Sp1 experiments has M_r of 27,000 (27K). The less purified mammalian TFIID used in the GAL4 and ATF experiments seems to be much larger[27] and protects a more extensive promoter region[15] than the yeast 27K protein[10] Perhaps the 27K protein is only one component of a larger complex, which may be the actual target of the activator. Such a complex could be disrupted during purification and then reassembled when the purified 27K protein is added back to the other relatively impure fractions. In fact, there is evidence that TFIID interacts with TFIIA[9]. Not all investigators require or use a separate TFIIA fraction[24,25], perhaps because the TFIIA polypeptide(s) remain associated with the TATA-binding activity.

Multiple targets?

While much effort has been expended in detecting interactions between gene-specific factors and TFIID, other possibilities remain to be explored. Given the apparent diversity of activating regions[21], it would be surprising if they all worked identically. There is evidence that some activators interact with RNA polymerase II, in particular its tail — the phosphorylated carboxyl-terminal repeat structure of the largest subunit. Removal of the polymerase tail eliminates transcription[28,29], and the effects of partial tail deletion can be compensated by a strong activator[30]. In addition, a column containing the activator GCN4 retains RNA polymerase II[31]. Furthermore, some activators may recruit basic transcription factors to the promoter, whereas others may function only after all the basic factors have been assembled (see figure); prokaryotic activators, for example, either recruit RNA polymerase to the promoter or act after RNA polymerase has bound (see ref. 32).

Other eukaryotic activators are implicated in regulating the elongation of the RNA transcript. The uninduced *hsp70* gene of *Drosophila* has a transcriptionally engaged RNA polymerase that forms a 25-nucleotide nascent RNA. RNA polymerase II is arrested at this position in the absence of heat induction[33]. And the transcription of c-*myc* may be down-regulated by retinoic acid in HL60 cells through premature termination[34].

Clearly there is still a great deal to be learned. But the cloning of TFIID and RAP30 provides two more important reagents to understand eukaryotic transcription regulation Ultimately, the reconstitution of transcription from purified components will be required to understand how activators interact with basic transcription factors. This may happen sooner than originally anticipated. The other subunit of TFIIF, RAP74, should soon fall to the cloners. More RNA polymerase II subunits are in the process of being cloned from yeast. The recent finding that yeast contains an equivalent to TFIIA (ref. 35) will undoubtedly facilitate cloning of the TFIIA gene. Finally, the power of yeast genetics will lead to the cloning of other genes. Understanding the exact assembly of the transcription complex and the role of each factor is a target in sight. □

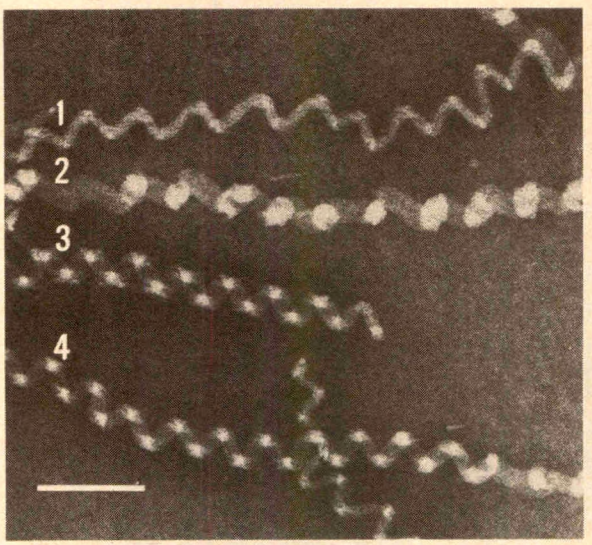
ASTRONOMY

Faint active galaxy puzzle

Lance Miller

ALMOST by definition, one would expect an active galactic nucleus to be bright. Yet A. V. Filippenko and W. L. W. Sargent report (*Astrophys. J.* **342**, L11–L14; 1989) that they have identified such a nucleus that is exceptionally dim. They recognized the active nucleus by its spectral features, but note that its optical luminosity is 10^5 times less than is usually associated with its type — indeed, it is less luminous than the brightest supergiant stars in our own Galaxy. Furthermore, the host galaxy is very unusual — a nearby dwarf that is a factor of about 10 less luminous than the galaxies in which active nuclei are usually found. The new results, thus, seem to follow in a frustrating tradition in research on active galaxies, whereby important new data confuse rather than clarify the issue.

Active galactic nuclei are extraordinarily bright regions at the heart of host galaxies, and are often termed Seyfert galaxies. Most commonly, it is supposed that their great luminosity is generated by the vigorous heating of gas and dust being accreted onto an extremely massive object, probably a black hole in their centre (see the recent News and Views article by Cedric Lacey, *Nature* **340**, 675–676; 1989). The new active nucleus appears as a faint star-like knot close to the centre of the galaxy NGC4395. Previously, it was assumed to be an H II region, a site of active star formation, although it was recognized as being extremely unusual (M. L. McCall, P. M. Rybski & G. A. Shields *Astrophys. J. Suppl.* **57**, 1–62; 1985).



Filippenko and Sargent have now obtained high-quality spectra of the knot, and these have the main characteristics of more luminous active nuclei; they identify the object as having the spectral features of a type-1.8 Seyfert nucleus. The profiles of the spectral lines due to hydrogen Balmer emission have strong narrow cores, indicating that the internal motion of the gas is largely negligible, but faint broad Doppler wings indicate the presence of some gas moving as fast as 3,500 km s^{-1}. Other emission lines indicate that the gas is present in a wide range of ionization states, for example both Fe^{9+} and neutral oxygen being detected. Filippenko and Sargent argue that the ionization is caused by a continuum of high-energy radiation, not by shock heating of the gas which would give different emission-line intensities.

The optical continuum underlying the atomic line emission is featureless, there being no absorption lines attributable to the presence of late-type stars. The relative strength of the emission lines and the continuum is in the range expected for Seyfert nuclei. Nevertheless, the spectrum does have some unusual features: despite the broad wings on 'permitted' lines, such as the Balmer lines, lines due to 'forbidden' transitions are extremely narrow, corresponding to a spread in atomic velocities less than 60 km s^{-1}, considerably below the value usually found for Seyfert galaxies, 300 km s^{-1}; and it seems from the line spectrum that the abundance of nitrogen relative to that of oxygen is anomalously low.

The principal puzzle concerns the source of the ionizing radiation. Because the spectrum looks like that from a normal active nucleus, it is reasonable to suppose that accretion onto a massive object is responsible. If this turns out to be the case, it would highlight how little we know of the origin of the activity. The brightest active galaxies include extended, powerful radio sources and are all massive elliptical galaxies. One can infer that the central object in these sources must contain at least 10^6 solar masses, as this is the minimum amount of material that must have been accreted to account for the energy stored in the radio lobes. Lower-mass, radio-quiet active nuclei are found mostly in lower-mass spiral galaxies, but even these are 10 times as massive as the dwarf galaxy containing the nucleus studied by authors. This most basic of observational trends relating the host galaxy to the active nucleus is not understood at all.

The authors put forward an alternative (hypothetical) source of the ionizing radiation, which would also account for

Self-assembling lipid helices

HELIX formation, it seems, is not the exclusive privilege of biopolymers. For the helical structures shown in these electron micrographs are formed not by continuous strands of nucleic acids folding to form internal networks of hydrogen bonds, but by the spontaneous self-assembly of chemically modified phospholipids, the principal constituents of biological membranes. In aqueous media, natural phospholipids have a tendency to aggregate forming micelles, monolayers and bilayer vesicles. But Hiroshi Yanagawa and co-workers at the Mitsubishi Kasei Institute of Life Sciences in Tokyo have discovered that simply by attaching the nucleoside cytodine, which contains one of the four bases responsible for helix formation in DNA, to the hydrophilic ends of phospholipids, they endow the molecules with the ability to form helical rather than layered structures.

Although the precise arrangement and degree of ordering of the modified phospholipids within the helices is not yet clear, it seems likely that the helical nature of the aggregates is a consequence of stacking and hydrogen bonding between nucleoside bases. Following their first report (Yanagawa, H., Ogawa, Y., Furuta, H., Tsuno, K. *Chem. Lett.* 269; 1988) describing the circular and linear helical strands formed by the phospholipid–nucleoside conjugates dipalmitoyl–5′–phosphatidyl cytidine and dipalmitoyl–5′–phosphatidyldeoxycytidine, Yanagawa and colleagues tested the effect on helix formation of shortening the alkyl chains of the lipid. They found that in contrast to the modified phospholipids of longer chain length, which form simple helices, dimyristoyl–5′–phosphatidyldeoxycytidine forms superhelices — helices of helical strands — examples of which are shown above. Strand 1 is a right-handed duplex with a diameter of about 110 Å and helical pitch of about 240 Å whereas strands 2–4 consist of a double duplex with similar diameter and helical pitch. The superhelical pitches of each of these strands are about 1,000 Å.

Commenting on these findings in a recent issue of the *Journal of the American Chemical Society* (111, 4567–4570; 1989), the authors propose a structural model for the single-stranded helix in which the conjugates are arranged in the form of a twisted micellar lipid bilayer — a kind of molecular spiral staircase in which the nucleoside groups frustrate the natural tendency of the lipids to stack side-by-side. David Concar

the low optical luminosity — a 'warmer', which is a cluster of highly evolved, hot, massive stars. R. Terlevich and J. Melnick suggested (*Mon. Not. R. astr. Soc.* **213**, 841–856; 1985) that such an object, in which stars could have effective temperatures as high as 100,000 K, could easily be mistaken for a Seyfert nucleus, having the same characteristics of ionizing radiation. The positive identification of one warmer would greatly support the hypothesis that many other galaxies have mistakenly been identified as Seyferts. The biggest problems in applying the warmer model to the nucleus of NGC4395 are accounting for the high velocities seen in the permitted lines, which imply extremely energetic outflow, for which no mechanism seems to be available, and the lack of spectral features seen in Wolf–Rayet stars, thought to be akin to the stars in a warmer.

Finally, if the nucleus studied by Filippenko and Sargent is in the family of accretion-driven Seyfert galaxies, it implies that even low-mass galaxies can be hosts to active nuclei, and that such faint nuclei may be common and are unknown because they are apparent in only the nearest dwarf galaxies. It is hoped that further studies of the nuclei of similar galaxies will clarify the relationship between galaxy type and activity. □

DROSOPHILA DEVELOPMENT

Making stripes inelegantly

Michael Akam

A STRIKING feature of *Drosophila* embryogenesis is the early appearance along the antero–posterior (A–P) axis of a precisely repeating pattern, the stripes of expression of the pair-rule genes[1,2] (see figure). This pattern depends upon the earlier expression of the segment gap genes, but these do not provide periodic cues; different gap genes are expressed in zones of varying width along the axis of the embryo. Periodicity might be generated in one of two ways. An elegant mechanism, favoured by model builders[3,4], would use an intrinsically periodic pattern-generating system, comprising the pair-rule genes and their products. This would only need to be triggered by local stimuli from the gap genes. Alternatively, unique instructions could be generated by the gap-gene proteins to define the position of each pair-rule stripe. Analysis of the interaction between gap and pair-rule genes seems to favour the less elegant 'specific instruction' process. Discrete elements within promoters for the pair-rule genes contain specific targets for the binding of one or more gap-gene proteins. These elements direct the expression of single stripes along the A–P axis[5–8].

Stripes on a *Drosophila* embryo — in this case somewhat abnormal *ftz* stripes (from ref. 22).

The expression of three gap genes spans the greater part of the segment pattern. The *hunchback (hb)* gene is activated in the anterior half of the embryo by direct interaction with a gradient of the protein expressed from the *bicoid* gene; successively more posterior regions of the embryo express *Krüppel* (*Kr*), then *knirps* (*kni*)[2,9]. When the distribution of transcripts from these genes is analysed, the region expressing each appears to be sharply bounded, defining abutting[10] or slightly overlapping[11] zones of expression. But the protein products of the gap genes are not so precisely localized. Antibodies reveal that the hunchback and Krüppel proteins accumulate in broader domains with no well-defined boundaries (see Fig. 4 of Stanjovec *et al.* on page 334 of this issue[8]). The apparent limits of these domains depend considerably on the sensitivity of the antibody staining techniques used[11]. Even so, it is clear that they overlap substantially. Within these regions of overlap, the relative concentrations of two gap proteins change continuously over a distance of at least 8–10 nuclei (about 2–3 segment primordia). It seems very likely that these graded changes in concentration and/or ratios of the gap gene products are providing cues for subsequent pattern generation.

Genetic studies indicate that all of the pair-rule genes are dependent on the gap-proteins for normal patterning, but that only three 'primary' pair-rule genes, *hairy*, *runt* and *even-skipped* (*eve*), are absolutely required to generate the periodic pattern[2]. Two of these primary pair-rule genes have now been shown to contain discrete promoter elements that mediate the generation of different parts of the stripe pattern. The first hint of this came from the study of mutations at the *hairy* locus[5]. Whereas most *hairy* mutants display segment fusions throughout the whole embryo, a subset of mutants causes segment fusion only in particular regions of the embryo. These mutants turned out to have deletions of different parts of the 5′-regulatory region of *hairy*. This implied the presence of region-specific promoter elements, in marked contrast to the organization of the promoter for the 'secondary' pair-rule gene *fushi-tarazu* (*ftz*)[12]. At *ftz*, promoter deletions generate either the complete set of stripes, or no stripes. This different organization supports the view that *hairy* responds directly to signals from the gap genes, whereas *ftz* responds only to periodic signals, generated by the pair-rule genes themselves.

A series of papers dissecting the regulation of the *eve* locus have amplified and confirmed this model[6–8,13]. The *eve* promoter proves to be particularly complex, in that it has both gap-response elements that mediate its initial activation, and a functionally independent element that responds to the accumulating products of the pair-rule genes. The pair-rule element becomes active somewhat later than the gap-response elements, and directs a distinct pattern of slightly narrower stripes.

So far, the gap-response elements have only been defined by deletion: regions of 1–2 kilobases of DNA within the 5′-regulatory region of *eve* specifically activate either stripe 3 or stripes 2 and 7 of the *eve* expression pattern. When truncated promoters containing the gap-response elements, but not the pair-rule response element, are re-inserted into embryos, they mimic very precisely the early expression of the endogenous *eve* gene in stripes 2, 3 and 7 (ref. 6). This activity remains dependent on the gap-gene products, but is unaffected by mutations in the pair-rule genes, implying that input from the gap genes alone can specify the location and width of the initial *eve* stripes.

It has been postulated for some time that the three gap genes, *hb*, *Kr* and *kni*, may be acting directly as transcription factors. Each encodes a putative zinc-finger protein[14–16] consistent with that notion. Strong evidence for this view is provided by three papers in this issue[8,17,18]. These demonstrate that the hunchback and Krüppel proteins bind to specific DNA targets. One of these studies examines the binding of these gap proteins to the *eve* promoter. Using footprinting techniques, Stanjovec *et al.*[8] find multiple binding sites for both proteins. Most of these are clustered within the elements that direct specific stripe formation.

The two other papers examine binding of the gap proteins to different potential target sequences. Treisman and Desplan[17] identify hunchback and Krüppel binding

sites upstream of the *hb* promoter; Pankratz *et al.*[18] define Krüppel binding sites upstream of the *kni* promoter. In each case, a very similar DNA sequence characterizes the Krüppel binding site, although *Kr* has been implicated as a negative regulator of *hb*, but a positive regulator of *kni*. The proposed hunchback binding sequences are more divergent. (It should be noted that there is no evidence that the hunchback protein binds to its own promoter, so the sequences defined by Treisman and Desplan[17] need not be functional.)

If Krüppel is acting directly by binding to the promoters of *kni*, and of the pair-rule genes, as these results suggest, then it must be functional at concentrations where the protein is barely detectable by present techniques. Pankratz *et al.* point out that an effect of Krüppel is observed throughout the zone of *kni* transcription, even though part of this lies beyond the detectable limits of Krüppel protein. *Kr* mutants alter the pattern of *eve* transcription in a region spanning *eve* stripes 2–6 (ref. 13), again suggesting that Krüppel is effective at, or beyond, the apparent limits of its distribution. This evidence for the action of the gap proteins at low concentrations throughout relatively large numbers of segment primordia, raises the intriguing possibility that the gap genes are effectively generating secondary gradients within the egg, extending from the boundaries of their zones of transcription.

The gap genes have been implicated in the primary regulation of the homoeotic genes, as well as in the segmentation hierarchy[1,19,20]. If the gap proteins are functional over a wide concentration range, they could provide positional information for the definition of precise segment identities, as well as for the positioning of the pair-rule stripes. Such information must be available within the blastoderm, but the discrete domains of gap-gene expression do not appear to provide sufficient resolution for this purpose. Local gradients of gap protein concentration could, however, provide the needed resolution.

If each pair-rule stripe is generated by the interpretation of a unique instruction, then the apparent simplicity of the repeating segment pattern is deceptive. A 'specific instruction' mechanism could generate an arbitrarily complex set of uneven stripes. The simplicity of the natural pattern must then be attributed to a process of selection needed to produce a set of evenly sized segment primordia.

Where does this leave spontaneous pattern-generating mechanisms? One very likely role for these processes is to amplify the initial discontinuities in pair-rule gene expression, and to sharpen the boundaries between stripes[21]. In this respect, the feedback circuits of the pair-rule genes act as bistable, or perhaps multi-stable, switches, forcing cells into one of a few preferred states. But it seems that they do not define periodicity. □

ATMOSPHERIC OZONE

Ultraviolet levels down not up

Stuart A. Penkett

Most people are familiar with the danger of ozone depletion in the upper atmosphere, and its probable consequences. Fewer are aware that the concentration of ozone in the lower atmosphere may be increasing. According to C. Brühl and P. J. Crutzen, in a recent issue of *Geophysical Research Letters* (**16**, 703–706; 1989), this increase could counteract the effect of the stratospheric depletion on the amount of ultraviolet radiation reaching the Earth's surface, especially in the Northern Hemisphere. This could mean that the increased incidence of skin cancer that many fear will follow stratospheric depletion, may not materialize. Instead, the effect in the changing concentrations would be seen most in atmospheric temperatures, with a warming of the troposphere and a cooling of the stratosphere.

Interest in the behaviour of tropospheric ozone is growing strongly, because it is an efficient greenhouse gas, it probably causes damage to vegetation at elevated concentrations and it has a large influence on the chemical reactivity of the troposphere through its ability to generate hydroxyl radicals on photolysis. It is now becoming accepted that the quantity of ozone is increasing in much of the troposphere. According to reports at a recent meeting*, ozone levels are increasing over both the continents and the oceans in the Northern Hemisphere. Also, it seems, the various chemical precursors of ozone — hydrocarbons and nitrogen oxides — are now spread throughout the troposphere. Observations of substantial concentrations of hydrogen peroxide, whose precursors react with nitrogen oxides to give ozone, underline this view of tropospheric ozone.

Brühl and Crutzen's new work concerns the different effect that tropospheric and stratospheric ozone have on the biologically active ultraviolet radiation (UVB) from the Sun. They argue that the path of light is less direct through the troposphere than it is through the stratosphere: this is because molecules, cloud droplets and aerosols, which are present in greater density in the lower atmosphere, scatter the light rays. The path length through the troposphere is thus relatively increased and each ozone molecule is more likely to intercept and absorb light.

The authors calculate the effect of this mechanism using data from the Hohenpeissenberg Observatory in Bavaria on the ozone concentration from 0–10 km (the troposphere) and above 10 km (the stratosphere). They find that between 1968 and 1982, the UVB reaching the Earth's surface actually decreased by 0.9 per cent at noon and by 0.5 per cent throughout the day. If a weighting factor is applied to the proportion of the UVB that interacts with DNA, the decreases calculated for noon and the whole day at the summer solstice become 1.7 and 0.9 per cent, respectively. This occurs in spite of an overall decrease in the ozone column density of 1.5 per cent, attributable to stratospheric depletion, over the same period. The contribution made by ozone in the troposphere is much more effective at lower solar zenith angles. At high solar zenith angles, which is the case for the winter months at high latitudes, the scattering of UVB mostly occurs in the traverse through the extended path length in the stratosphere.

Brühl and Crutzen emphasize the role played by increased absorption of ultraviolet by ozone throughout large parts of the remote troposphere. Its effect will be much more pronounced in the Northern Hemisphere where ozone concentrations have increased substantially over the past 50 years (S.A. Penkett in *The Changing Atmosphere* (eds F.S. Rowland & I.S.A.

* *Tropospheric Ozone*, Norwich, 3–7 July 1989.

Isaksen) 91–103 (John Wiley, Chichester, 1987)). Their paper also counters suggestions that measurements indicating a decline in UVB in urban areas of the United States during 1974–1985 were unrepresentative because of the large scattering caused by aerosols in local pollution. In my opinion, sulphate aerosol concentrations (the principal scatterer) are unlikely to have increased in the urban United States during the past 20 years. It is more likely that they will have remained constant or declined as they have in the United Kingdom (L. Salmon *et al. Sci. tot. Env.* **9**, 161–200; 1978) because of the increased use of cleaner fuels. □

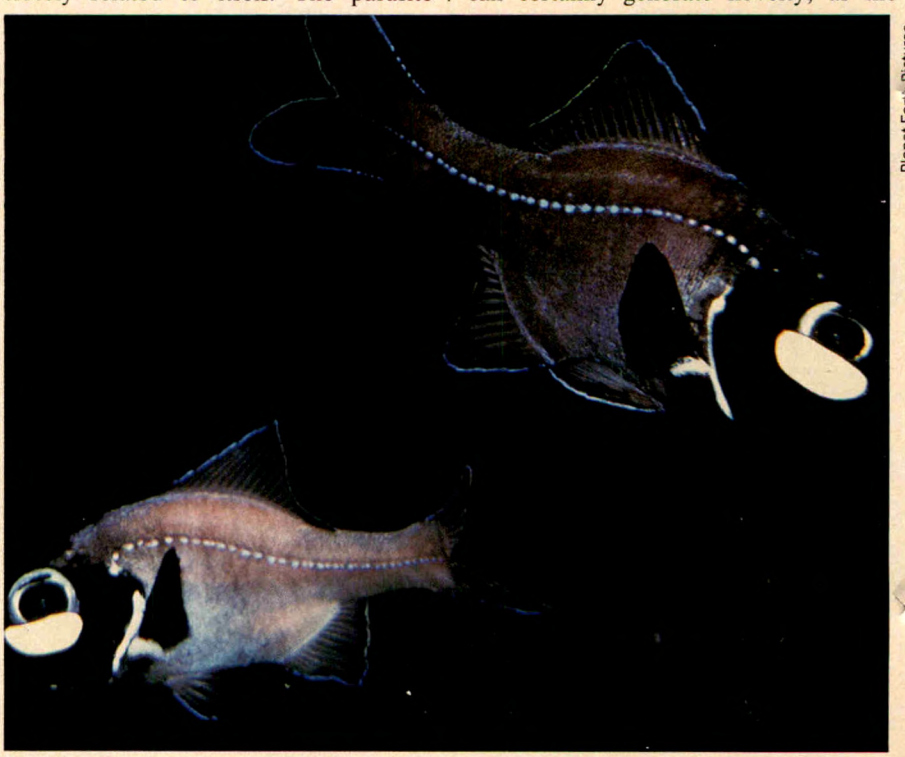
EVOLUTION

Generating novelty by symbiosis



John Maynard Smith

Most biologists now accept that the evolution of eukaryotes from prokaryotes involved the symbiotic union of several previously independent ancestors: a host cell, a mitochondrial ancestor, a chloroplast ancestor and, more controversially but more importantly, a prokaryote that brought with it the structures that today provide cell motility — undulipodia — and that move things around inside cells — microtubules, centrioles and the spindle. We are also uncomfortably aware that the success of bacteria in defeating our attempts to kill them with antibiotics depends on their ability to acquire the necessary genes from elsewhere, usually on plasmids. What these two processes have in common is that genetic material from two very different ancestors is brought together in a single descendent. Did some, or even most, other major novelties in evolution arise in an analogous way? A number, at least, of those attending a recent conference* on symbiosis would answer in the affirmative. As one who was invited as a potential critic of this view, I will first summarize some of the facts that were reported, and then give my own opinion of their significance.

On a number of occasions, plants and animals have acquired important metabolic capacities through symbiotic union with prokaryotes, or with fungi. Termites digest cellulose with the help of a diverse population of protists and bacteria in their gut. Ericaceous plants are dominant on acid peat soils because of their relationship with a single species of mycorrhizan fungus, which makes available nutrients inaccessible to other plants. Aphids and leaf-hoppers can live on plant phloem because their cells contain bacteria able to perform syntheses that their hosts cannot (T. Tiivel, Estonian Acad. Sciences, Tallin): a similar relationship exists between some weevils and their intracellular bacteria (P. Nardon, Laboratoire de Biologie Appliquée, Villeurbanne), but in this case the insects can survive, albeit with reduced fertility, in the absence of the bacteria. The Leiognathid fishes use light organs to assist vision, and to give signals (M. J. McFall-Ngai, U. Southern California, Los Angeles) and the light is generated by potentially free-living luminescent bacteria, although some other fishes generate light using enzymes programmed by their own chromosomal genes. Finally, the Pogonophoran worms that inhabit deep-sea vents (and also the Lucinid bivalves that live, less romantically, in the sewage outflow from Los Angeles) do not feed as adults, but rely instead on the energy supplied by endosymbiotic bacteria that oxidize hydrogen sulphide and use the energy to fix carbon (R. Vetter, Scripps Institute Oceanography).

This list, although incomplete, is impressive. Of course, not all symbiotic relationships are mutualistic. The most remarkable parasitic relationship described occurs in red algae (L. J. Goff, U. California, Santa Cruz). Often, a host species of red alga is infected by a parasite closely related to itself. The parasite transfers a nucleus into the host cell, where it undergoes DNA synthesis and division, and in effect takes over from the host nucleus. It is tempting, but still speculative, to suggest that this situation has evolved from normal fertilization, with the male nucleus becoming parasitic on the female cytoplasm. However, it is the mutualistic cases that seem to offer the best hope of evolutionary novelty, and it is these that I shall discuss.

The first issue concerns 'gradualism', and the contrasting possibility of relatively sudden innovation by symbiosis. Here I see no serious contradiction. I am a gradualist because I do not believe in miracles. A single mutation can produce a large morphological effect, but it would be a miracle if it were to give rise to a complex adaptation. If I were told that a fish had acquired, in a single mutational step, the five genes that code for the enzymes that generate bioluminescence, I would not believe it. But I see no difficulty with the idea that a fish could acquire luminescence by symbiosis with a bacterium that already possessed the necessary genes. The problem of miracles, however, does not disappear. The bacterial genes themselves had to evolve, and they presumably did so by mutation and selection. Similarly, the complex light organs of the fish, with their reflectors and movable shutters, had to evolve, and again they presumably did so by mutation and selection: it would be a miracle if the mere presence of the bacteria induced, at a stroke, a complex structure of benefit to the fish. Nevertheless, the bringing together of genetic information from two unrelated sources can certainly generate novelty, as the

Planet Earth Pictures

Flashlight fish (*Photoblepharon palpebratus*) of the Comores Islands, illuminating symbiosis.

*Symbiosis as a Source of Evolutionary Novelty, Bellagis, 25–30 June, 1989.

examples listed above illustrate.

A second question concerns the kinds of novelty likely to arise in this way. Prokaryotes and fungi are good at metabolic tricks that animals and plants have lost, or never had — an obvious example is vitamin synthesis. Symbiosis with them may provide new metabolic abilities, but is less likely to be relevant in the evolution of new modes of locomotion or feeding, which is what palaeontologists tend to have in mind when they talk of macroevolution. I therefore doubt whether symbiosis has been important for the morphological evolution of plants and animals, except in so far as it may generate selection for morphological change, as in the example of luminescent organs in fish. Even if a symbiont induces a morphological change in its host (and examples of this were reported), the host response, if adaptively complex, has to evolve by natural selection.

A final problem concerns the selective mechanisms responsible for the origin of symbioses. Parasitic interactions present no special difficulty, but mutualism is more puzzling: why should a symbiont benefit its host if it could gain immediate advantage by injuring it? The decisive questions concern methods of transmission and multiplicity of infection. The bacterial endosymbionts of weevils and of plant-sucking bugs can live only in their hosts, and are transmitted in the host eggs. Hence a symbiont that damages its host reduces its own chances of leaving descendants. But most symbioses probably passed through a stage in which the association had to be re-established in every generation. This is still the case for the other examples listed above. Larval Pogonophora have a mouth, and swallow their future symbionts Young fish swallow luminescent bacteria, young termites must acquire their gut symbionts, usually through the rear end — this may be one reason why they become social — and seedling plants re-establish contact with mycorrhiza in every generation.

With this life history, the spread of selfish mutations, converting a mutualistic relation into a parasitic one, is always a possibility. Yet all the above examples are ancient. One possible explanation for their stability is that few selfish mutations are possible. For a fungus, a heather plant is an excellent supplier of fixed carbon, and it may be better to keep alive the goose that lays the golden eggs than to kill it. But this argument depends on the assumption that, if you do not kill the golden goose, no one else will either: that is, it assumes that the host is infected by a single clone of symbionts. The same argument applies to the evolution of parasites from greater to less virulence.

Further work is needed on the origin and maintenance of symbiosis, but it is already clear that, by bringing together genetic material from distantly related ancestors, symbiosis provides a source of evolutionary novelty that is additional to mutation and homologous genetic recombination. □

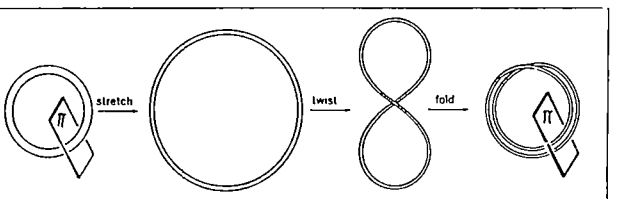
ASTROPHYSICAL MAGNETISM

Stretch, twist and fold

H.K. Moffatt

Dynamo action, in astrophysical contexts, is the spontaneous growth of magnetic fields caused by the motion of electrically conducting fluids. That fluid motion can sustain a magnetic field against its natural tendency to decay is well-established, but there are doubts about the rates at which magnetic fields grow when the conditions for dynamo action are satisfied. It appears still to be an open question whether there can be a smooth velocity field capable of generating a fast dynamo action, in the sense of the distinction[1] between 'fast' and 'slow' introduced by Vainshtein and Zeldovich[2] in 1972. That question, and the surprising connections that have emerged recently with the theory of iterated maps, were explored at a recent workshop*.



Dynamo theory is important in planetary physics and astrophysics because of the ubiquity of magnetic fields Nearest to home, the Earth's magnetic field is sustained by dynamo action in the outer liquid core, and the magnetic fields of Jupiter and Saturn and possibly of other planets are believed also to originate from fluid dynamos. If it were otherwise, these fields would decay in times of the order of 10^4 years, which is short compared with the age of the Solar System, throughout which, on geological and other evidence, the fields have persisted.

Stellar and, in particular, solar magnetism presents another problem. The natural decay time for a magnetic field may be 10^9 years, but there are systematic variations such as the 22-year solar sunspot cycle on much shorter timescales. Rapid changes such as these, involving global reversals of magnetic polarity, must be attributable to fluid motion deep in the turbulent stellar convection zone. Whether galactic magnetic fields also originate in dynamos is another matter[3].

The property of fluid motion crucial to dynamo action is helicity — in simple terms, the net imbalance between right-handed and left-handed helical motion. Surprisingly, it has recently been shown[4] that Ponomarenko's helical dynamo[5], perhaps the simplest and purest of all, in which helical streamlines are confined to a cylinder, is a fast dynamo, but only when the velocity is discontinuous across the cylinder boundary. The other known model of fast dynamo action is that of Soward[6], who has shown that certain spatially periodic velocity fields have the properties of a fast dynamo provided that there are mild singularities of vorticity at the stagnation points.

These examples are somewhat contrived, which may in part explain why the search for other more realistic examples has excited so much interest. The physical, rather than mathematical, prototype of a fast dynamo is that first discussed by Vainshtein and Zeldovich[2], and may be likened to the process of stretching, twisting and folding a rubber band so as to double the tension. A similar procedure applied to a magnetic flux-tube in a perfectly conducting fluid (see figure) will double the magnetic field-strength, so that indefinite repetition of the stretch–twist–fold sequence will lead to exponential growth of the magnetic field on a timescale determined by that of the motion, and independently of molecular diffusion. This example, of course, is also somewhat contrived: but insofar as stretching is invariably associated with turbulent flow, twisting with convection and folding with geometrical constraints thereon, the stretch-twist–fold sequence has some basis of reality in the turbulent convection zone of a rotating star.

How can one translate this physical argument into mathematical form? The stretch–twist–fold sequence can be represented as a three-dimensional time-dependent velocity field, but the resulting equation for the evolution of the magnetic field is so complex that it cannot be solved even with available computing power. But now there is an alternative procedure. The stretch–twist–fold sequence doubles the magnetic field-strength without increasing the cross-section of the flux-tube, which is tantamount to a mapping of the cross-section onto itself.

The stretch–twist–fold sequence, showing the plane of cross-section Π on which the associated mapping is constructed.

*Workshop meeting at Observatoire de Nice, 25 - 30 June, 1989

That observation alone links dynamo theory with the theory of iterated mappings, about which much is known. Several examples of iterated mappings, called dynamo maps, have now been found, notably by Bayly and Childress[7] and by Finn and Ott[8], and were scrutinized at the workshop. It emerges that, although every time-periodic flow yields a map and every continuous map can be associated with a flow, it is not yet known whether these flows have the property of 'orientability' that would lead to reinforcement (rather than cancellation) of the convected magnetic field. That fundamental problem remains an obstacle in attempts to tackle dynamo theory with the theory of iterated maps

There remains the sledge-hammer of the high-speed computer. The velocity field most likely to be tractable, is called the 'ABC' flow — essentially a superposition of three orthogonal circularly polarized velocity fields such that the velocity field **u** has the components $(B\cos ky + C\sin kz,\ C\cos kz + A\sin kx,\ A\cos kx + B\sin ky)$. This flow is named after Arnol'd (who recognised that the particle paths may be chaotic), Beltrami (who first conceived of flows such as this in which the vorticity is everywhere parallel to the velocity) and Childress (who recognized the flow, through its property of maximal helicity, as a prime candidate for dynamo action).

Galloway and Frisch[9], following Arnol'd and Korkina[10], have computed the dynamo growth-rate as a function of the magnetic Reynolds number R_m (a dimensionless measure of electrical conductivity), and find two windows of dynamo action, in the ranges $8 < R_m < 18$ and from $R_m = 27$ up to $R_m = 400$, the present limit of reasonably accurate computation The challenging question still outstanding is whether the ABC flow generates a fast or slow dynamo, or no dynamo at all, in the limit in which R_m tends to infinity.

A novel twist to this question was raised at the meeting by B.J.Bayly (University of Arizona, Tucson), following work by A.A.Ruzmaikin (Moscow). If the three ingredients of the ABC flow associated with the parameters A, B and C are successively switched on and off at random, separated by periods when only diffusion operates, the result is a model reminiscent of the 'stasis' model of Backus[11], who provided one of the first proofs of dynamo action — in the event, a slow dynamo. Bayly has now shown that fast dynamo action is also possible and, interestingly, that the wavelength of the growing magnetic field is exactly twice that of the underlying ABC ingredients of the flow. This behaviour has escaped attention in previous computations, which have concentrated on magnetic fields with the same periodicity as the velocity field. Bayly's result, if confirmed, is certain to stimulate further computational attacks on the ABC problem.

An explicit fast-dynamo theory is potentially of the greatest importance in astrophysics because present accounts of stellar magnetism are based on insubstantial foundations. Most modern theories follow the mean-field formalism introduced by Steenbeck, Krause and Radler[12] in which the effects of turbulence in convection zones are parameterized by a generation coefficient α and a turbulent diffusivity β, which are usually related to the velocity and length scales of the turbulent convection by simple dimensional analysis. The resulting growth rates are determined by α, β and global properties such as differential and meridional circulation in the star, but do not depend on the magnetic diffusivity of the medium, so that the dynamos are intrinsically fast Thus the whole theory of stellar magnetism hangs on the slender thread of dimensional analysis applied in a complex turbulent context. The mathematical difficulties inherent in fast dynamo theory are concealed in the mean-field theory which, in principle, determines α and β, but there is a paradox: the molecular magnetic diffusivity seems to be essential to the production of an α-effect even though the resulting value of α is independent of the value of the diffusivity, which is in any case vanishingly small.

If the solar dynamo is, indeed, a fast dynamo, then it is to be expected on dimensional grounds[13] that the field will nearly everywhere have a fine scale of the order of $\sqrt{R_m}$ multiplied by L, the length-scale of the velocity field. Taking L to be of the order of 1,000 km from the observed granulation of the solar surface, and R_m to be of the order 10^4, there should be variations of magnetic field on scales as small as 10 km, which is not incompatible with observation. Fast dynamo theory may therefore be of much more than merely academic interest. □

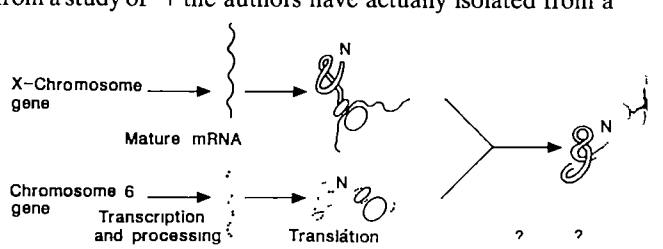
PROTEIN STRUCTURE



One enzyme from two genes?

Lucio Luzzatto

GLUCOSE-6-PHOSPHATE dehydrogenase (G6PD) has long been a favoured system in human biochemical genetics. It was one of the first mammalian enzymes to be characterized[1], it is one of the most polymorphic genes in the human genome[2] and, because it maps to the X-chromosome (Xq28)[3], it has served as a wonderful marker to study X-chromosome inactivation[4], the consequent mosaicism of somatic cells in females[5], and the clonality of tumours[6]. In addition, this mosaicism is probably responsible for the biological advantage of G6PD deficiency with respect to malaria[7] Now, an entirely unexpected development, of potentially general significance, arises from a study of G6PD just published in *Cell*[8]. If the work is confirmed, we shall have to adjust to a new way of thinking about how proteins can be assembled.

Briefly, Yoshida and his colleagues find that whereas one form of G6PD in red cells has an amino-acid sequence that conforms to that predicted by the cDNA sequence first published by Persico *et al.*[9], another form differs upstream of amino acid 36. By the use of two synthetic oligonucleotides corresponding to portions of the divergent sequence, they have isolated human genomic and reticulocyte cDNA clones that encode this sequence as part of a protein of 345 amino acids, the gene for which maps to chromosome 6 rather than the X chromosome.

They must, of course, have considered the possibility that the G6PD preparation used for protein sequencing was contaminated. But the remarkable result, on which the rest of the paper depends, is that the authors have actually isolated from a

Can a hybrid protein be formed during or after the translation of separate gene transcripts? And, if so, how?

red-cell G6PD preparation a tryptic peptide of 21 amino acids which, on sequence analysis, consists of 13 amino acids encoded by the chromosome 6 gene followed by 8 amino acids encoded by the X-chromosome gene. From this, Yoshida and colleagues infer that the major human-red-cell G6PD consists of an N-terminal portion of 52 amino acids encoded by a chromosomes-6 gene, attached to 479 amino acids encoded by the X-chromosome gene

Unprecedented

How can such an unprecedented hybrid protein be formed? Attempts to isolate a hybrid cDNA (which might have resulted from *trans*-splicing of two separate primary transcripts) must have been strenuous, but were not successful: indeed, probes belonging to the two genes light up mRNA species of different sizes Therefore, the authors are led to the conclusion that splicing of the two molecules must take place either at the stage of translation (ribosome 'hopping'), or at a post-translational stage (transpeptidation) Barring the unfortunate eventuality of transpeptidation having taken place as an artefact *in vitro*, no other explanation seems possible

Of course, this raises a host of questions For instance, what cells have the transpeptidation machinery, and how is its specificity guaranteed? What is the fate of the C-terminal portion of the chromosome 6 protein, and of the N-terminal portion of the X-chromosome protein after transpeptidation? Does the full chromosome 6 protein exist, and what is its function?

Whatever the answers to these questions may be, the biological significance of site-specific transpeptidation, if it occurred generally, would be of considerable magnitude. As far as I know, the only precedents are the addition of ubiquitin to proteins before their degradation (but in this case an *iso*peptide bond is formed through an ε-amino group on lysine), and the post-translational processing of concanavalin A (but in this case portions of the same translation product, rather than two different translation products, are ligated together[10]) Despite introns, and despite the many variations on the theme of alternative splicing, recombination at the RNA level has not made any serious dent in the concept of the mendelian gene. recombination at the polypeptide level certainly would

Synthesis

Coming back to G6PD, there are four reasons that argue against the chromosome 6 gene being of major importance with respect to synthesis of the enzyme First human G6PD made in rodent–human somatic cell hybrids containing the X as the only human chromosome is indistinguishable from normal human G6PD[11]. Second, G6PD produced in COS cells[12] from a construct containing that cDNA is indistinguishable by electrophoresis from human-red-cell G6PD. Third, G6PD produced in *Escherichia coli*[13] using a similar construct is (from our unpublished results) also indistinguishable in size, charge and kinetics from human-red-cell G6PD; therefore, if the G6PD produced by transpeptidation is the principal species in red cells, one would have to conclude that, despite its different size, net charge and N-terminus, its physical and enzymic properties are somehow identical to the G6PD encoded by the X-chromosome gene alone. Finally, there is an evolutionary argument because Yoshida and colleagues find that the chromosome 6 gene is apparently limited to primates, whereas G6PD as a whole is highly conserved in evolution, what is the unique role of the N-terminal portion of the protein in the red cells of primates?

In the past two years, analysis of G6PD variants identified from clinical and population studies has begun to give us a picture of the molecular basis for the 300 or so alleles of this locus Thus far, only point mutations have been observed[12], and none has been in exons I or II The accumulation of more data on mutants may help us to understand why the gene is so polymorphic (is it also more mutable?), and to pinpoint functionally important domains The fact that no deletions have turned up supports the biased view of G6PD fans that this is not just a housekeeping gene but is actually indispensable for house management. The startling report by Yoshida's group could set us up for the ultimate surprise· a G6PD deficiency that will be autosomal instead of X-linked □

DAEDALUS

High impurity

ATMOSPHERIC chemistry is very perverse. At ground level, ozone and nitrogen oxides are pollutants. Ozone forms photochemical smog and nitrogen oxides contribute to acid rain. Twenty kilometres up, however, they are transformed into goodies. The high ozone layer is formed by, and protects us from, the far-ultraviolet component of sunlight. And nitrogen oxides help to protect the ozone layer. For stratospheric ozone is catalytically decomposed by halogen radicals, perversely formed from the halocarbon gases which are so benign and useful at ground level. Just one such halogen radical can destroy thousands of molecules of ozone in an efficient chain reaction. Nitrogen oxides, formed from the stratosphere's small content of nitric acid, combine with and deactivate these radicals. So Daedalus, in the cause of environmental purity, is planning to inject large amounts of nitrogen oxides into the stratosphere.

The cure may seem worse than the disease — acid rain is more damaging than ultraviolet light. But Daedalus will inject his oxides indirectly, as ammonia gas. This reacts with ozone to give nitrogen oxides. Each ozone molecule lost in the oxidation will save thousands of its fellows from destruction.

The great advantage of this indirect approach is that ammonia is lighter than air. In principle your could loft it to the stratosphere in big balloons. Daedalus's plan is even more elegant — he is scaling up vortex-ring technology. A vortex ring, of course, travels as a self-contained parcel of gas, and exchanges very little with its environment. Furthermore, a vortex ring of buoyant ammonia would have inherent lift. It would not slow and dissipate like a smoke-ring, but would rise to a great height like a sort of skinless balloon. DREADCO chemical engineers are building huge pulse-pipes from which big vortex rings of ammonia can be fired upwards at the stratosphere. They are seeking the ideal size and velocity for an ammonia ring that shall just reach the ozone layer before turbulence and diffusion break it apart. Some of its ammonia is bound to escape into the atmosphere on the way up, to be washed out again by rain. Ammonia-rain, of course, would be alkaline — a useful counter to acid rain.

This elegant scheme has many advantages. Ammonia is one of the few chemicals made in tonnages vast enough to have a significant effect on the atmosphere, even in the modest catalytic role here proposed. Sooner or later it will come down again, adding to the precipitation of combined nitrogen and helping to fertilize the planet at large. As ammonia is mainly used as a fertilizer anyway, the ground-level economy will remain largely unaffected.

David Jones

Safety in the laboratory

SIR—We wish to report briefly on two matters of laboratory safety that have been raised recently in Scientific Correspondence.

The first concerns the claim by Arnold *et al*[1] that the existence of channels and pores in latex gloves revealed by scanning electron microscopy raises doubts about whether such gloves are effective barriers to viruses It was subsequently pointed out that these channels may be artefacts of sample preparation[2] and that there is no evidence that viruses are able to pass through latex gloves[3,4] We have now found that gloves worn in clinical and research laboratories can be readily penetrated by a bacterial virus — bacteriophage lambda.

We compared the ability of gloves made of thin polyethylene (PE), polyvinyl chloride (PVC) and latex to be penetrated by this virus both before and after exposure to the disinfectant ethanol (70 %). Sections of the gloves that cover the palm were tested under static conditions. Gloves of PE and PVC failed to be effective barriers to the virus in 40 % and 22 % of trials, respectively, rising to 94 % and 56 % after exposure to alcohol. The trials using latex gloves had a failure rate of 1–2%. Although this study did not involve specific human pathogens, it serves as a warning to those selecting gloves for handling biohazardous materials and illustrates the need for better glove testing standards and quality control.

Our second report is in response to the findings[5,6] that many solutions of ^{35}S-methionine release volatile radioactive component(s), which can present containment problems. We have not found incubators used for ^{35}S-labelled compounds to be as highly contaminated as those reported[5] We studied the volatility of ^{35}S-methionine under controlled conditions in open and closed containers After incubation for 4 hours in closed containers, only 0.01–0.1 % of the ^{35}S was in volatile form. Although the volatile component was readily soluble in water, its loss — a function of the volume incubated and the vapour pressure — was independent of the evaporation of water from the incubation medium. Reliance on charcoal filters to trap the volatile ^{35}S-compound[5] is unwarranted as binding of the compound to such filters was found to be non-quantitative and reversible

The release of volatile ^{35}S-component(s) can be controlled by incubating culture vessels in a sufficient volume of media (14 ml mCi^{-1}) in an incubator with high humidity to reduce the evaporation rate of the incubation media, or by using a CO_2- gassed and sealed flask, or by using Petri dishes in sealed plastic bags. Tricine (50 mM), an effective stabilizer, should be added to the media if it is not toxic to the biological agents in culture.

More detailed reports of our findings have been submitted for publication elsewhere.

Periodical cicadas

SIR—Martin and Simon[1] suggest that 13-year cicadas in a large region of central North America are descendants of 17-year cicadas that switched their life-cycle length to 13 years. Their proposal that brood XIX in Illinois, Iowa and Missouri represents a permanent four-year acceleration from brood X that took place in 1868 is not supported by the historical record.

As Martin and Simon[1] point out, four-year accelerations are common in periodical cicada life cycles But one-year decelerations are also known[2]. I have analysed over 1,500 historical records of periodical cicada emergences dating back to 1804 in Illinois, Indiana, Kentucky and Ohio for patterns of emergence in a given locality The results show that over 98 per cent of the records are for known broods, four-year accelerations or one-year decelarations from established broods. Moreover, in May/June 1988, two counties in southwestern Ohio and two counties in northern Kentucky witnessed an unexpected emergence of periodical cicadas. The emergence was as heavy as brood X which emerged in the region a year earlier and involved all three species. Examination of the hatch rate indicated it was as high as brood X, a long-established brood, possibly fore-telling of a future brood which would be numbered brood XI. The brood was heaviest in an area where brood XIV is the predominant brood Moreover, brood XIV also experienced a one-year deceleration in 1975 in the same area which produced the 1988 emergence. If the unexpected 1988 periodical cicadas were derived from brood XIV it would suggest that the 1988 emergence was a four-year acceleration from the 1975 one-year deceleration. This combination of a four-year acceleration with a one-year deceleration would explain areas, such as northeastern Ohio, where adjacent broods V and VIII occur with three-year differences in their emergences.

Historical records will not indicate mechanism, but they can give important evidence for different models. Lloyd and coworkers[3] have proposed a mendelian model for four-year accelerations involving a hybridization between 17- and 13-year cicadas. But the Ohio history shows four-year accelerations in regions where only 17-year cicadas occur Twelve counties in Illinois and much of southwestern Missouri recorded periodical cicada emergences in 1829, 1842 and 1855 indicating that the 13-year life cycle of brood XIX in Illinois and Missouri was established before 1868 (ref. 4). This does not speak against the proposed mechanism presented by Martin and Simon, rather it suggests that the acceleration that gave rise to brood XIX may have occurred earlier than they thought.

GENE KRITSKY
Department of Biology,
College of Mount Saint Joseph,
Mount Saint Joseph,
Ohio 45051, USA

SIMON AND MARTIN REPLY—The complex patterns of periodical cicada emergences are indeed mind-boggling as Kritsky points out. His painstaking historical analyses have shown that despite their much touted reputation, periodical cicadas are not as regular as clockwork. Nevertheless, the irregular emergences are far from random, being either one or four years out of phase. Furthermore, Kritsky's historical data base has proved invaluable in interpreting genetic patterns[1,3,5]. For example, as he notes, hybridization between 13- and 17-year cicadas is not, as proposed[3], a necessary condition for an acceleration in development.

We[1] have presented data which suggest that, in the midwest, a region that had been occupied by both 13- and 17-year cicadas is presently inhabited exclusively by cicadas possessing a 13-year life cycle but a 17-year genome. These cicadas are genetically identical to 17-year brood X which disappeared from the area in the first half of this century. Our conclusion is that midwestern 13-year cicadas of brood XIX originated from 17-year brood X by a four-year acceleration in development and joined an existing 13-year brood XIX which abutted it to the south.

We agree with Kritsky that the proposed four-year acceleration may not have occurred in 1868 but the presence of 13-year cicadas in the area before 1868 does not rule out this hypothesis. Indeed, a four-year acceleration of midwestern 17-year cicadas to produce 13-year cicadas could have occurred more than once. Despite the particular pathway that produced the geographical and temporal pattern we observed, both Kritsky's historical data and our genetic data indi-

cate that year-class formation occurs as a consequence of changes in life-cycle length.

The question that now needs to be addressed is, are these pre-1868 cicadas genetically 13-year or 17-year? If we can obtain alcoholic or dried specimens from 1829, 1842 or 1855, we can determine their mitochondrial genotype through DNA amplification and sequencing as we have done for other preserved periodical cicadas (Simon and Paäbo, unpublished data). A search is underway; anyone with information on such specimens is urged to contact us.

Parasites and sexual selection

SIR—Recent discussions about the prevalence of blood parasites and colour in birds[1,2] have resurrected a debate which began in 1982 (ref 3) but aroused little interest among parasitologists who had hoped that the whole matter would die quickly and quietly. In my view, all this work is strong on evolutionary theory and statistics but so weak on basic parasitology that the fundamental basis upon which the edifice has been erected is suspect.

The basis of the work has been published data on parasite numbers in stained blood smears, which are notoriously difficult to interpret even by experts. Overall, a single blood smear presents only a tiny window through which real infection can be glimpsed. It requires an almost superhuman effort to examine the whole of a blood smear properly, so short cuts are usually taken[4]. Furthermore, given the many factors that affect infection, the true prevalence of any blood parasite cannot be determined by single blood smears. It requires several sequential smears taken over a long period of time to be fairly sure, and an immunological or molecular test to be virtually certain that a host is infected with a particular parasite In this context, Zuk[2] finds it intriguing that rarely trapped birds show a stronger correlation between brightness and parasites more than commonly caught birds. The explanation for this is simple — and here I plead guilty — for when examining blood smears, one takes much more care if they come from rarer birds because these are more likely to produce observations justifying publication

We know practically nothing about the pathology of many blood parasites that infect birds, and what we do know comes largely from laboratory observations or anecdotal evidence. Some parasites can kill their hosts, but some hosts exhibit a phenomenon known as premunition during which a tolerable infection prevents the establishment of a less tolerable one. Furthermore, other concomitant infections cannot be ignored because blood parasites are markedly affected by the presence of other parasites, bacteria or viruses. Practically nothing is known about immunity to parasites in passerines and it is futile to try to make any assumptions about the ways in which these blood parasites affect the lives of their hosts.

It therefore does not seem surprising that there is no agreement as to whether there is any connection between the colour of birds and the presence of blood parasites. To a parasitologist, the only suggestion that makes any sense is that of Read and Harvey[1] who suggest a phylogenetic relationship. It would be interesting to see this followed up in a systematic way.

F. E G. COX

Division of Biomolecular Sciences,
King's College London
26 Drury Lane,
London WC2B 5RL, UK

1 Read, A F & Harvey, P H *Nature* **339**, 618–620 (1989)
2 Zuk, M *Nature* **340**, 104–105 (1989)
3 Hamilton, W D & Zuk, M *Science* **218**, 384–387 (1982)
4 Smith, V W & Cox, F E G *Ibis* **114**, 105–106 (1972)

HAMILTON AND ZUK REPLY—Before responding to Cox, it is necessary to deal with inaccuracies in Read and Harvey's response[1] to Zuk[2]. Her claim (on which both of us, as authors of the original paper[3], agreed) was that Read and Harvey's reanalysis[4] in fact produces significant correlations between male brightness and parasite prevalence in passerine birds. This is not wrong. Read and Harvey[1] evidently mean that it would be wrong to claim such correlation after their procedures for removing 'taxonomic association' have been applied, but Zuk's letter was not referring to this case but to ordinary cross-species comparison, as in our original paper[3]. Almost every dataset has some potential classification underlying it which has not yet been 'controlled'. It is not wrong to say that a study on a school class reveals a 'significant correlation of exam mark with writing speed' just because there are several ethnic groups in the class. 'Controlling' an underlying complex of relationships in such a case may clarify and it may also deny evidence of an important cause. However, even had we made the claim that Read and Harvey criticize we would still be half right: their report tells that on the side of the Atlantic where the new scorers were treating familiar birds the association within taxa had P=0.008.

They seem to reject this because it reduces if species with small sample sizes are excluded. That new fact is very interesting but does not contradict either our actual claim or the stronger one they treat as made. As to reasons, we suggested one which Harvey and Read reject. Whether that argument is wanting or not, a point not clear to us, another that can be independent or auxilliary is confidently suggested by Cox in his letter in this issue. Thus, it now seems that the most carefully assessed bird species — those rarely caught, on Cox's authority — after scoring by local ornithologists and statistical removal of taxonomic artefact, accord very well with our expectation[4,5]. Thus the combination of data and analysis which all five contributors to this correspondence most nearly agree to be valid rejects no association with P=0.003 (two-tailed) and shows association in the direction we predicted[4]

That more infections are apparently added for showy birds than for dull when smears are carefully searched is also interesting. Low-level infections in showy birds fit well with theory because sexually selected species, co-evolving faster, may be better able to keep them low Read and Harvey also suggest this in a different context, claiming we discounted the possibility. We did not, although we do expect sexual selection only to be able to diminish parasite incidence, not eliminate species.

Cox's comments on the weaknesses of the data are similar to those we found in most of the original papers. However, all authors who reported data had enough faith in their methods to think it worthwhile to tabulate numbers of birds caught and cases found. Provided there is no reason to expect a capricious relationship between observed and true incidence our test can proceed. It is remarkable and reassuring that from such weak data all the 'showiness' calculations, now done for three continents with contributions from three sets of scorers, have uncovered correlations of the same type.

We share Cox's wish for better understanding of the parasite conditions. We would especially like to see chronic virus conditions included in cross-species surveys. We do not agree with Cox, however, that it is futile to assume that passerine parasitaemias are usually detrimental, even though some studies on particular genera have failed to show this[6]. Both the known immense impact of disease associated with parasitaemia in humans and domestic animals, and a well-supported theory of how virulence might be maintained when parasites have mobile vectors[7], reinforce this assumption. Even if it is true that certain infections can be

tolerated by many individuals, this does not remove these from the ambit of our theory Indeed, a tentative connection between committment to symbiotic microbes and sexual selection is indicated in a variety of disparate taxa from anelgesid mites to ruminant ungulates[8].

We also join Cox in hoping that the 'phylogenetic relationship' found by Read and Harvey[4] ('association' in their terms) will be followed up. Its slant is consistent in the studies carried out and suggests to us the following possibilities in accord with our thesis first, parasites bring high sexual selection, and this, through stringent mate choice, encourages speciation[9-11]; second, non-conforming trends (costly sexual selection with no payoff to descendants' health, or no sexual selection when parasites are damaging) reduce species survival.

Armenian earthquakes

SIR—A recent report[1] on the 1988 Armenian earthquake raises important issues concerning earthquake hazard and tectonic deformation rate in this region. The figure shows part of its fault scarp, indicating what seems to be an older Holocene scarp sub-parallel to it. Assuming that the local soil formed near the end of the Pleistocene glaciation (~10,000 years ago,) the estimated recurrence interval of major earthquakes on this fault is about 5,000 years or more, and the 2-m Holocene throw implies an average slip rate of ~0 2 mm yr^{-1} or less The 1988 earthquake occurred on one of a set of parallel reverse faults with ESE strike, some of which had been identified previously[2-5], that take up shortening across Armenia and the adjacent Soviet Transcaucasian republics. The largest known historical earthquake in what is now Soviet Transcaucasia occurred in 1668 near Shemakha[4-6], now in

The view looking WNW from latitude 40'49 9' N longitude 44'13 1' E showing, highlighted by shallow snowdrifts, the 1988 fault scarp at ~1,900-m elevation, ~500 m east of its highest point, and the suggested older scarp up to 10-m farther north to its right, both with ~1-m reverse throw Both scarps can be followed along strike for ~500 m in soil that is probably late glacial or early post-glacial (~10,000-yr old), given the presence of moraine deposits and glacial cirques at similar elevation nearby The arid climate and the absence of local soil disturbance by agriculture (in contrast with lower elevations) favour scarp preservation The abrupt 1988 scarp has been trenched, but the trench stops ~2-m short of the other, more rounded, scarp. It is hoped that this trench will be extended northward and radiocarbon dating of samples from it will provide quantitative constraint on the Holocene slip history suggested for this fault Both scarps probably merge into the same active reverse fault at a few tens of metres depth, which dips NNE (to the right) at ~60' The photograph was taken in February 1989 The sketch shows an interpretation, with chevron markers indicating the hanging walls of both scarps which are uplifted relative to the footwalls

Soviet Azerbaijan. The ~50-km WNW–ESE extent of severe damage, more than in 1988 indicates M_s (surface-wave magnitude) ≈7. Including the 1988 event (M_s = 6.7) only five Transcaucasian earthquakes in the past 1,200 years, or so, are known[6] to have caused damage equivalent to M_s 6 5–7 (ref. 6). Co-seismic slip rate on other individual faults must, therefore also be very low, and the shortening rate across Transcaucasia can be no more than a few millimetres a year[7]. Nonetheless, it seems prudent to base regional earthquake hazard planning on the assumption that an earthquake with $M_s \geq 7$ may occur on any of these faults, with a probable recurrence interval for such events on any individual fault of many thousands of years. Furthermore, the suggested low regional deformation rate means that many geomorphological features such as river terraces identified[1] in Armenia and believed to be related to active faulting are probably far too old to be radiocarbon dated.

Reader Service No.41

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

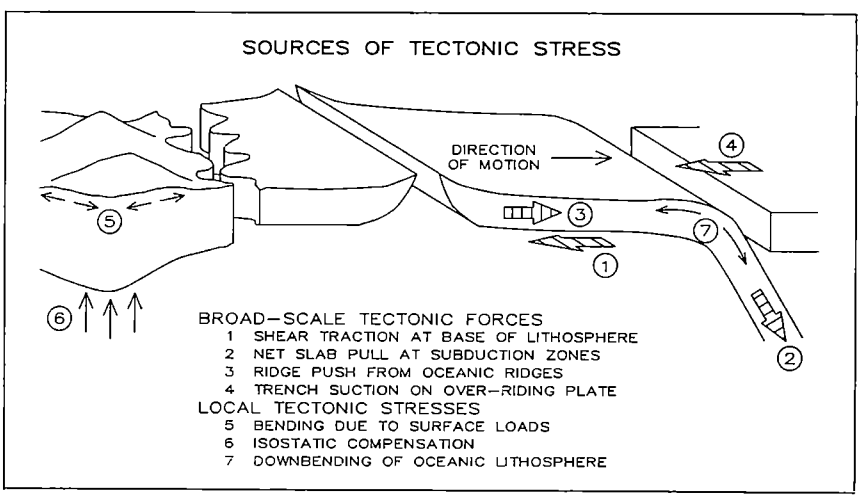
Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

Submission. *All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

Global patterns of tectonic stress

Mary Lou Zoback, Mark D. Zoback, J. Adams, M. Assumpção, S. Bell, E. A. Bergman, P. Blümling, N. R. Brereton, D. Denham, J. Ding, K. Fuchs, N. Gay, S. Gregersen, H. K. Gupta, A. Gvishiani, K. Jacob, R. Klein, P. Knoll, M. Magee, J. L. Mercier, B. C. Müller, C. Paquin, K. Rajendran, O. Stephansson, G. Suarez, M. Suter, A. Udias, Z. H. Xu & M. Zhizhin

Regional patterns of present-day tectonic stress can be used to evaluate the forces acting on the lithosphere and to investigate intraplate seismicity. Most intraplate regions are characterized by a compressional stress regime; extension is limited almost entirely to thermally uplifted regions. In several plates the maximum horizontal stress is subparallel to the direction of absolute plate motion, suggesting that the forces driving the plates also dominate the stress distribution in the plate interior.



Two primary categories of forces are responsible for the state of stress in the upper, elastic part (reaching to depths of 10–35 km) of the Earth's lithosphere. The first category is responsible for what we shall call here 'tectonic stresses'. These broad-scale forces include plate-boundary forces (which either drive or resist plate motion), forces resulting from geodynamic processes (including broad-scale flexure of the lithosphere owing to surface and subsurface loads and/or inhomogeneous density distributions), and thermoelastic forces in cooling oceanic lithosphere. The second category is derived from local effects of topography, anisotropy of strength or elastic properties, and effects of erosion and man-made excavation; these forces generate local or 'induced' stresses. Spatial uniformity of the *in situ* stress field generally allows us to distinguish easily between these two categories. For example, tectonic stresses typically are uniform over distances many times (from 2–3 times to more than 100 times) the thickness of the elastic part of the lithosphere, whereas local stresses have wavelengths that are a fraction of this thickness. Induced stresses are critical in many mining and civil-engineering situations, but tectonic stresses provide valuable constraints on a variety of broad-scale geological problems such as the relative magnitudes of plate-driving forces and the nature of deformation and seismicity in the plate interior, far from plate boundaries (so-called intraplate or midplate deformation).

The World Stress Map project of the International Lithosphere Program is compiling a global database of contemporary *in situ* stresses in the crust using a variety of geophysical and geological measurement techniques. The project is a collaborative effort which at present involves over 30 scientists from 19 different countries. This project builds on early investigations of stress patterns in central and eastern North America and in western Europe, which indicated that both horizontal stress orientations and relative stress magnitudes are uniform over broad regions of the Earth's crust[1–10]. A comprehensive compilation and analysis of the state of stress of the contiguous United States[11] which used both geological and geophysical stress indicators, confirmed the regionally uniform stress orientations found in the earlier studies and also concluded that stress orientations inferred from different types of indicator were generally consistent, despite the variety of techniques being used and the different ranges of depth being sampled.

Here we focus on these regionally uniform, broad-scale stress fields in the lithosphere. The most probable sources of such stress fields are the major forces acting on lithospheric plate boundaries. These forces include: shear tractions at the base of the lithosphere that can either drive or resist plate motion; a 'slab pull' force which represents a balance between the negative buoyancy of the subducted oceanic lithosphere, viscous drag on the subducting slab and frictional resistance to subduction at shallow depth; resistance to continent–continent collision; a 'ridge push' force resulting from the excess thermal elevation of young oceanic lithosphere; and a 'trench suction' force exerted on the overriding plate at subduction zones, which is caused by trenchward extension of this plate to fill the gap that results from the falling back of the subducted slab (see refs 12–19 for detailed discussions of these forces).

Geological evidence, thermodynamic considerations[17] and relatively short timescales for changes in plate motion all suggest that viscous drag at the base of the plates resists, rather than drives, plate motion and probably balances the torque caused by driving forces on individual plates[19,20]. Drag forces thus tend to act antiparallel to the direction of 'absolute' plate motion relative to the lower mantle. Slab-pull, trench-suction and collisional-resistance forces all act normal to plate boundaries. The ridge-push force is an integrated force acting over the cooling oceanic lithosphere and generally acts normal to the plate boundary, except where spreading is oblique to the ridge. Here we shall approximate the orientation of the ridge-push force within a plate by the local orientation of relative motion calculated from the pole of opening for mid-ocean-ridge segments.

More localized sources of tectonic stress include flexural (bending) stresses caused by surface loads supported by the strength of the lithosphere (for example, resulting from sediment

deposition or volcanic loading, mountain building and erosion), by subsurface loads required for isostatic compensation of topography (that is, adjustment of lithospheric density in response to variability of overlying load), by down-bending of the oceanic lithosphere in subduction zones, and by membrane stresses generated by the motion of plates over an Earth of varying radius of curvature[21]. From a global perspective perhaps the most significant of these forces is the combined effect of the surface load and the buoyancy of a low-density region (thickened crust and/or thin mantle lithosphere) supporting a region of high topography. If the buoyancy forces dominate they can produce a broad zone of deviatoric tension beneath major mountain ranges and high plateaus[18,22,23].

As indicated previously, lateral variations in strength or elastic properties can result in local induced stresses. However, in some cases these variations are so profound and are of such long wavelength that they dominate the tectonic stress field. The best documented example of this effect is an apparent ~50–60° rotation of the horizontal stresses in a 100–125-km-wide zone on either side of the right-lateral San Andreas fault in California, the boundary between the Pacific and North American plates. It is suggested that this rotation results from an extremely low shear strength of the San Andreas fault and the slightly convergent relative motion between the two plates[24,25]. Geological and focal-mechanism data[26] suggest that a similar stress rotation occurs adjacent to the right-lateral strike-slip Alpine fault in New Zealand, the plate boundary between the Pacific and Indian–Australian plates.

Stress measurement

A variety of data indicate that the three principal stresses in the Earth's upper crust lie in approximately horizontal and vertical planes[11], as suggested by E. M. Anderson[27]. Thus, the orientation of the principal axes of the stress tensor can be constrained by specifying the azimuth of one of the horizontal principal stresses. Absolute stress magnitudes at depths of earthquake generation are extremely difficult to obtain and it is generally possible to constrain relative stress magnitudes only from the style of active faulting or deformation occurring in a region (see box).

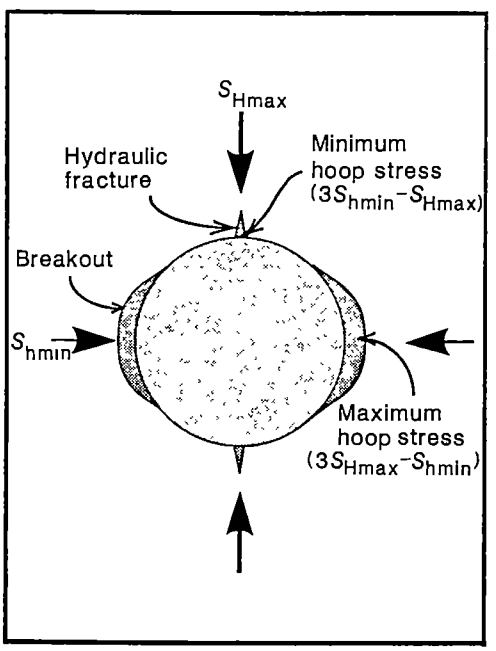


FIG. 1 Stress concentration around a vertical circular hole in an elastic half-space subjected to unequal far-field horizontal stresses, S_{Hmax} and S_{hmin}. As indicated, breakouts and hydraulic fractures form as a result of these stress concentrations.

- *In situ* stresses in the elastic part of the Earth's lithosphere are compressive (below the upper tens of metres).
- Principal stresses lie in approximately horizontal and vertical planes:
  S_V = vertical stress $\approx \rho gz$
  S_{Hmax} = maximum horizontal stress
  S_{hmin} = minimum horizontal stress
- Relative stress magnitudes determine type of deformation:
  Normal faulting: $S_V > S_{Hmax} > S_{hmin}$
  Strike-slip faulting: $S_{Hmax} > S_V > S_{hmin}$
  Thrust or reverse faulting: $S_{Hmax} > S_{hmin} > S_V$

Four different categories of geophysical and geological data are used at present as reliable indicators of horizontal stress orientations: earthquake focal mechanisms, stress-induced well-bore enlargements or 'breakouts', *in situ* stress measurements, including hydraulic fracturing and stress-relief measurements, and young geological deformational features, including both fault-slip and volcanic alignments.

A quality ranking system was developed recently[28] to aid in the analysis of the tectonic stress field in the lithosphere. This system permits a comparison of data collected by these different techniques and, in particular, aids in evaluating the significance of data in areas of sparse coverage. The ranking criteria are based both on the accuracy of individual determinations and on the relative reliability of the technique as an indicator of tectonic (as opposed to local or induced) stress. Four qualities are used, ranked in the order A > B > C > D. An A quality is assigned to data that record the tectonic stress field to within ±10–15°, a B quality to within ±15–20°, and a C quality to within ±25°. In some cases D-quality data may record the *in situ* stress field reasonably accurately but because of a variety of potential perturbing factors (such as topography and free-surface effects) these data are not generally considered to be reliable indicators of tectonic stress.

These four main types of stress indicator have been described previously[2,11,19,28]. The major recent advances that have made possible the compilation of global stress data are as follows.

Borehole breakouts as a reliable indicator of horizontal tectonic stress orientation. According to elastic theory, the maximum compressive circumferential stress developed around a vertical borehole is centred on the azimuth of the least horizontal far-field stress (S_{hmin}), and the minimum stress occurs in the direction of the maximum horizontal stress (S_{Hmax})[29] (Fig. 1). Well-bore breakouts are a natural phenomenon that result from shear fracturing in the region of maximum stress amplification[30,31]; they cause a cross-sectional enlargement of the hole in the direction of S_{hmin}. In contrast, hydraulic fracturing is an active technique in which a portion of the well-bore is isolated and pressurized by injected fluids until a tensile fracture develops in the direction of S_{Hmax}. The orthogonality of breakouts and hydraulic fractures within a single well has now been confirmed by down-hole experiments in several wells in various tectonic settings[31–33].

Numerous investigations have established that consistently oriented breakouts form within an individual well and in wells within a given field[32–39]. This possibility of multiple determinations in an individual well, and the ability to check for regional consistency among numerous wells, make breakout data valuable indicators of stress orientation. In addition, because wells for petroleum exploration and production are often drilled to depths of 3–4 km (and in some areas, up to 5–6 km), breakout data help to bridge the gap between the near-surface stress indicators (which sample typically less than 1 km depth) and

earthquake focal mechanisms (of typically 5–15 km depths). As can be seen in Fig. 2, there is generally an excellent agreement locally between stress orientations determined from well-bore breakouts and those inferred from earthquake focal mechanisms[25,28].

Resolution of earthquake focal mechanisms. Largely as a result of waveform modelling made possible by digital seismic acquisition networks, more and better-constrained focal mechanisms are now available. In addition, routine moment-tensor inversion of global network events[40] has greatly increased the database. An inherent difficulty remains, however, in estimating principal stress directions from focal mechanisms[41–43]. Focal mechanisms are constructed from the radiation pattern of seismic waves, which defines a set of two possible orthogonal fault planes and slip vectors. P and T axes correspond to the maximum shortening and extensional strain directions for these shear faults.

But most crustal earthquakes are presumed to occur on pre-existing faults, in which case the fault-slip vector is a function of the orientation of the pre-existing fault and of both the orientations of the principal stresses and their relative magnitudes[41,44–46]. Because of the uncertainty in inferring stress directions from earthquake focal mechanisms, a single mechanism, regardless of how well constrained, does not receive an A-quality ranking. This highest ranking is reserved for stress directions determined from mean P- or T-axis orientations or formal inversions for best-fitting stress axes[47–51] of groups of moderate-sized earthquakes (at least one event with magnitude >4.5) occurring within close geographical proximity and with a variety of focal mechanisms. When using average P and T axes it is commonly assumed that errors resulting from slip on pre-existing planes of a variety of trends tend to cancel statistically[11,52]. In general, aftershock sequences are not used because in some cases they appear to record deformation that is a secondary adjustment in response to slip in the main shock[53,54]. A number of cases, however, show no discernible differences in stress orientation and relative magnitudes before and after the main shock[55,56].

Inversion algorithms to infer deviatoric stress tensors from fault slip and focal mechanism data[46–51,57–59]. The underlying assumption of these inversion algorithms is that the measured slip vectors represent the direction of maximum resolved shear stress on the fault planes[44,45]. Slip vectors, determined from striations observed on small fault planes of a variety of attitudes along active fault zones, are then inverted to yield a best-fitting deviatoric stress tensor. The inversion methods for fault-slip data[48,57–59] are essentially the same as those used for focal-mechanism data[47,49–51] and, in both cases, yield principal stress orientations that are generally well constrained[50]. However, fault-slip inversions yield more precise information on relative stress magnitudes, because the true fault plane is known. The validity of this technique has been established by numerous studies which have demonstrated a reasonable match between predicted and observed slip vectors[48].

Often, particularly for historical earthquakes, only the overall slip vector and general attitude of the fault plane are known. In this case the data are treated as a palaeo-focal mechanism and the stress directions are inferred by the method of Raleigh[42]. These data are generally given a B-quality ranking. C-quality fault-slip stress determinations are estimated from the general attitude and primary sense of offset (but not actual slip vector) on an active fault plane.

Volcanic alignments as reliable horizontal stress indicators[60]. Volcanic feeder vents such as dykes and cinder cones propagate perpendicular to the minimum principal far-field stress as natural, large-scale hydraulic fracturing experiments[61]. Thus, the mean strike of vertical dykes corresponds to the direction of S_{Hmax}. To study the current state of stress one uses vents of Quaternary age; however, palaeo-stress can be similarly studied using older dykes or cinder cones that are radiometrically dated.

Critical evaluation of stress relief measurements. One of the earliest and best studied techniques for investigating the state of stress in the Earth's crust is stress-relief measurements, commonly referred to as 'overcoring' measurements. This technique involves determination of the natural three-dimensional deformation (strain) relieved in a body rock *in situ* when separated from the surrounding rock volume[62,63] and is the only technique that measures the complete stress tensor. Amongst the primary drawbacks of this method are that the measurements must be made near a free surface (either the Earth's surface or an excavated surface in a mine), that the strain relief is determined over areas of only a few mm^2 to cm^2, and that the change of stress on overcoring must be calculated from the strain relief, which requires knowledge of the complete compliance tensor. In particular, near-surface surface-stress-relief measurements have been shown to be subject to effects of local topography, rock anisotropy and natural fractures[64]. Because of these difficulties, we have assigned a D quality to all near-surface (<5–10 m, depending on local site conditions) stress-relief measurements in the database. For stress-relief measurements made at depths >10 m (or at least one excavation diameter away from the free surface in a mine) the assigned data quality depends on the internal consistency of multiple measurements.

Global stress patterns

The first global map of stress orientations was published by Ranalli and Chandler in 1975[64] and contained 59 stress-relief measurements. In 1979, Richardson *et al.*[19] presented a map containing about 133 points worldwide, derived primarily from earthquake focal mechanisms supplemented by surface overcoring measurements and geological data. Much of the data shown on these maps we would now categorize as rather low-quality (C or D) indicators of tectonic stress.

At present there are 3,574 entries in our global database; 3,142 of them are assigned either an A, B or C quality and are plotted on Fig. 2. As mentioned earlier, the emphasis in this paper is on the tectonic stress field, so D-quality data are not plotted. The length of each data point in Fig. 2 is proportional to its quality and the centre symbol designates the type of stress indicator. The distribution of the data by measurement type is as follows: earthquake focal mechanisms, 50%; breakouts, 31%; hydraulic fracturing measurements, 3%; stress relief, 7%; volcanic alignments, 4%; and fault-slip data, 5%. Distribution of areal coverage according to quality is given in Table 1.

A single horizontal stress orientation, S_{Hmax}, is plotted on Fig. 2 to facilitate the recognition of regional patterns of stress orientation. Relative stress magnitudes (stress regime) are indicated by colour for all data for which they are directly determined. Plotted in red are data that indicate an extensional stress regime (defined here as one in which the vertical stress is the

FIG. 2 World stress map, transverse mercator projection S_{Hmax} orientations are plotted, length of lines are proportional to quality (A, B or C). Because the data coverage is so dense in the western United States, only A- and B-quality data are plotted there Centre symbol designates type of stress indicator. Data indicating an extensional stress regime are plotted in red, data for a compressional regime are plotted in green, and data where stress regime is unknown are plotted in black All regions with average elevation greater than 1 km are indicated by blue shading Lightly dashed lines correspond to absolute velocity trajectories determined using AM1–2 poles of Minster and Jordan[65] Wavy line approximates the 80-Myr isochron on the Pacific plate

greatest principal stress); normal or combined normal and strike-slip faulting characterize this regime. The data in green indicate a compressional stress regime, in which one or both of the horizontal stresses are greater than the vertical stress; deformation in this regime is characterized by thrust, strike-slip or combined thrust and strike-slip faulting. Stress orientations for which information on relative stress magnitudes was not determined directly or not reported are plotted in black. Unfortunately this is the case for all of the breakout data, which comprise nearly one-third of the data set.

Regions with average elevation greater than 1,000 m are indicated on Fig. 2 by shading. Also shown are absolute plate-velocity trajectories, calculated using Minster and Jordan's[65] poles of angular motion for each plate (model AM1-2).

Three broad generalizations can be drawn from the data. (1) Most midplate regions are characterized by compressive stress regimes, that is, by thrust and/or a combination of thrust and strike-slip deformation. (2) Most continental areas of extensional stress regimes (normal or combined normal and strike-slip faulting) are regions of anomalously high elevation (for example, the western US Cordillera, the East African rift, the Baikal rift, the Himalayas and the Andes). (3) Broad regions of the Earth's crust are subjected to a nearly uniformly oriented stress field, specifically a $\sim 2\times10^7$-km^2 region (approximately one-eighth of the world's land surface) of north-east to east-north-east compression in central and eastern North America and a $\sim 6\times10^6$-km^2 region of north-west to north-north-west compression in western Europe.

In the midplate portions of some plates there is a striking correlation between S_{Hmax} orientations and azimuths of absolute plate velocity (as indicated by the trajectories in Fig. 2). This correlation is illustrated by the histograms in Fig. 3, which show, point by point, the angular difference between the observed S_{Hmax} orientation and the local absolute-velocity azimuth. In these plots the local absolute-plate-velocity direction is the reference direction; hence positive angles in Fig. 3 represent observed S_{Hmax} directions oriented clockwise with respect to that reference direction. It is important to note that because these histograms represent a point-by-point count and not a regionally averaged fit, they are strongly influenced by regions of dense data distribution. Furthermore, all data of A to C quality are treated equally, not weighted by quality.

Figure 3 indicates a strong positive correlation between S_{Hmax} orientations and absolute velocity directions on the two fastest-moving continental plates: midplate North America (including most of the central and the eastern United States, much of Canada and possibly the western Atlantic basin) and the South American plate. The correlation is particularly striking for midplate North America, the area of densest and highest-quality data coverage in the world; here the angular differences show a near-normal distribution about the reference absolute velocity direction. Breakouts on the outer continental shelf in eastern North America contribute to scatter in the histogram (see shaded areas on Fig. 3); detailed analysis of these data indicate that S_{Hmax} orientations are often rotated into a plane approximately parallel to the local trend of the continental slope. This rotation may be the result of superposition of stresses owing to flexure from sediment loading on the continental shelf[66].

The strong positive correlation between S_{Hmax} and absolute velocity directions for midplate North America has been interpreted by some workers as indicating that resistive drag at the base of the plate is the primary source of stress in the upper lithosphere[67]. However, as pointed out previously, the absolute velocity vector in midplate North America coincides within $\sim 10°$ with the expected direction of the ridge-push force from the Mid-Atlantic Ridge[28,68–70]; therefore the two mechanisms cannot be distinguished as possible sources of stress for this plate. Similarly, for the South American plate, the approximately east-west absolute velocity is within 10° of the ridge-push direction inferred from the South American–African pole of relative motion. In addition, convergence between the South American plate and both the Nazca and Pacific plates is also approximately east-west. Thus, for both the North and South American plates it is not apparent which source of stress, if any, is dominant. Overall, the simplest explanation for the correlation between S_{Hmax} and absolute-plate-velocity directions on these plates is that the net balance of forces that move the plates dominates the stress distribution within the plate interiors.

In western Europe the S_{Hmax} directions and absolute-plate-velocity directions seem to be relatively well correlated (Fig. 2), except in the Aegean. However, as indicated in Fig. 3, the data consistently indicate a clockwise rotation of S_{Hmax} with respect to the absolute-velocity direction, that is, the observed S_{Hmax} orientations trend more northerly than the west-north-west absolute-velocity field. S_{hmin} directions in the Aegean region (orthogonal to the S_{Hmax} directions shown in Fig. 3) are also clockwise with respect to the direction of plate motion. However, it should be noted that the absolute-velocity rotation pole for Eurasia is very poorly constrained because this plate is moving so slowly in an absolute reference frame[65]. Thus, the significance of the difference between the S_{Hmax} and absolute-velocity direction is unclear.

Another potentially significant source of stress in Western Europe is the force resulting from the continental convergence of the African and Eurasian plates. Overall, S_{Hmax} orientations seem to be relatively well correlated with the predicted convergence velocity field obtained using the African–Eurasian pole of relative motion from the NUVEL velocity model[72] (see histogram in the lowermost left corner of Fig. 3). S_{Hmax} orientations in the Aegean are generally orthogonal to the convergence direction (see below). However, the average S_{Hmax} direction of N 42° W obtained from the extensive breakout data set in the United Kingdom[71] is more northerly than that predicted from the velocity field for this region on the basis of either the absolute-velocity directions (N 62° W), ridge-push forces (N 70° W), or continental-convergence forces (N 56° W). To properly evaluate the stress field resulting from these plate-boundary forces, however, detailed two- or three-dimensional finite-element modelling is needed.

There is the suggestion of a weak correlation between S_{Hmax} and absolute-velocity directions in the Pacific plate, although the data for this plate are few in number and derived primarily from earthquake focal mechanisms. Data from older (north-western and western) portions of the Pacific plate have S_{Hmax} orientations that are generally orthogonal to absolute-velocity directions (Fig. 3). S_{Hmax} orientations in the younger portions of the Pacific plate are quite scattered with respect to absolute plate motion; however, if events near the East Pacific Rise are excluded, S_{Hmax} orientations in the younger portions of the plate are sub-parallel to the absolute plate-velocity direction (Fig. 2). Interestingly, this change in S_{Hmax} orientations coincides roughly with the 80-Myr isochron, the point at which the $t^{1/2}$ subsidence of cooling oceanic lithosphere dramatically slows down from $t^{1/2}$ to an approximately exponential decay[73]. However, once again, spreading directions in the Pacific Plate, using relative motion poles with respect to both the Nazca and Antarctic plates, are aligned within 10° with absolute plate-motion vectors, so forces owing to ridge push and drag cannot

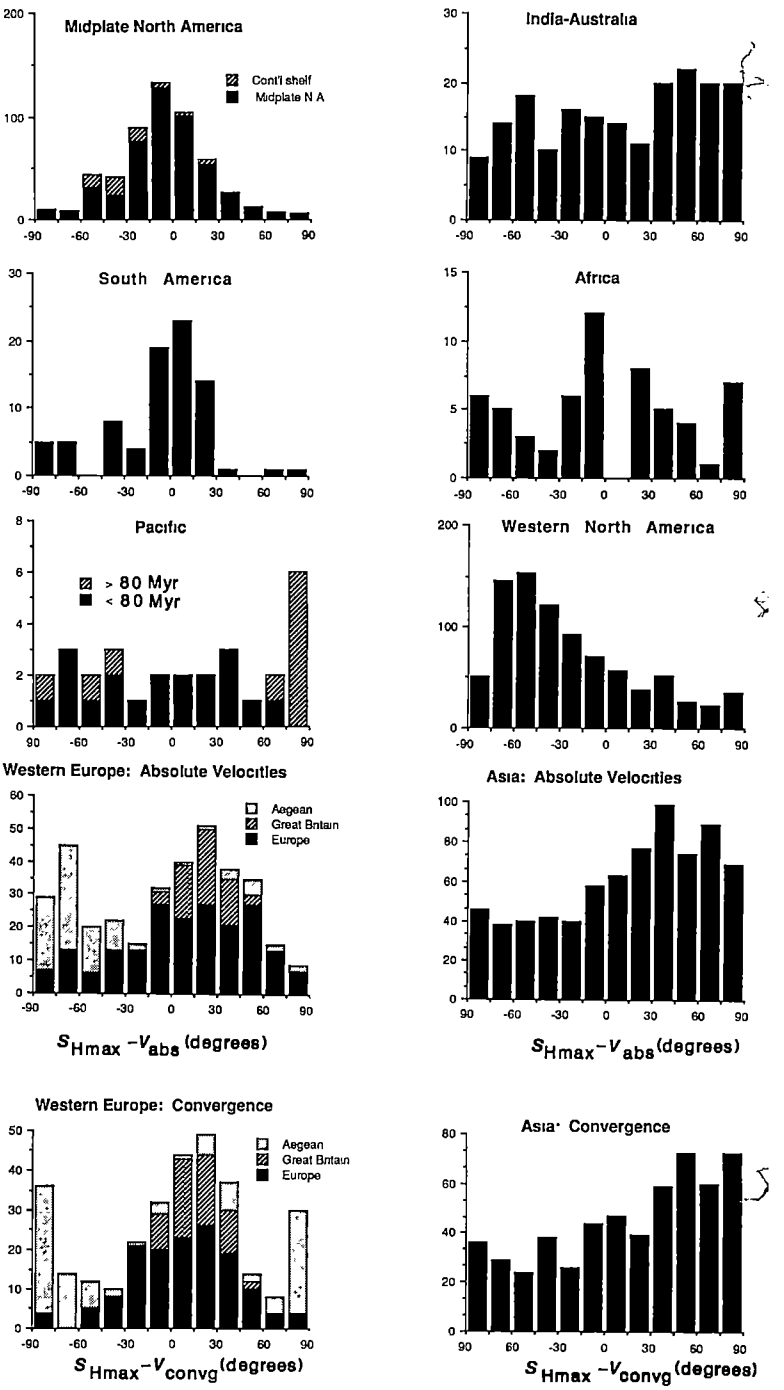

FIG 3 Histograms comparing, point by point, the angular difference between observed S_{Hmax} orientations and a computed velocity field for specific plates, subplates or regions. Upper four histograms in both columns compare observed stress directions with absolute-velocity directions, and the lowest histogram in each column compares observed stress directions with relative (convergent) velocity directions (see text).

be distinguished. Although single-force finite-element models of resistive drag[19] predict variations in relative stress magnitudes across the Pacific plate that are consistent with the observed stress rotation, it is impossible to determine the source of this apparent polarity change between S_{Hmax} and S_{hmin} without detailed modelling that includes all potential forces acting on the plate.

Figure 2 and the plots in Fig. 3 indicate that there is no clear correlation between S_{Hmax} and absolute velocity in several major regions, for example, much of Asia, the Indian–Australian plate, the African plate and the largely extensional and thermally uplifted western US Cordillera. Data for the Antarctic, Nazca and Cocos plates are too sparse either to confirm or to contradict any possible correlation.

The pattern of stress throughout eastern Asia is strongly influenced by the collision of the Eurasian and Indian–Australian plates. Within the Himalayan collision zone the S_{Hmax} orientations are generally north–south, subparallel to both the absolute motion of the Eurasian plate[65] and to the relative (convergent) motion between the Eurasian and Indian–Australian plates[72]. However, in eastern China, S_{Hmax} trajectories form a quasi-radial pattern which is oblique to both the absolute and the relative plate-motion directions (see histograms in the lower right corner of Fig. 3). This quasi-radial pattern of S_{Hmax} orientations is well predicted by indentor-type models[74] for the continued collision of the Eurasian and the Indian–Australian plates.

As indicated on Fig. 2, the pattern of S_{Hmax} orientations for

the Indian–Australian plate is rather complex; in particular, data for the Australian continent, a relatively stable intraplate region, show great variability (in contrast to stress patterns in midplate North America, for example). A high level of intraplate seismicity within the Indian Ocean has attracted a lot of interest in attempts to model the plate-driving and other tectonic forces acting on this plate[75–77]. In these models, Himalayan collision generally accounts for the north-easterly compression in the eastern Indian Ocean, whereas complex intraplate stress patterns throughout the rest of the plate generally result from the complicated plate geometry and the varying nature of subduction along the Sunda and Tonga–Kermadec arcs.

Regions of extensional stress

As shown in Fig. 2, areas of extension on the continents occur primarily in regions of anomalously high elevation. These areas of extension occur in a variety of tectonic settings: a broad zone of distributed shear (western North America), an intraplate setting (Baikal and African rifts), a continental-collision zone (Himalayas), and above a subduction zone (Andes). The latter two examples are regions of relatively rapid plate convergence in which the extension direction is generally orthogonal to the convergence direction. In contrast, in true 'back-arc spreading', extension occurs in a direction generally orthogonal to the arc boundary, so that extension is often subparallel to convergence direction. Modern examples of back-arc spreading generally occur in topographically depressed areas such as the Mariannas basin and other western Pacific basins (all of which are currently unsampled by the database). The modern low elevation of the Aegean region is best explained by Pliocene back-arc spreading which was subsequently replaced by modern (late Pleistocene to present) extension parallel to (that is, S_{Hmax} perpendicular to) the convergence direction[78] (see histogram in lower left corner of Fig. 3).

The relationship between elevation and extension is complex. For example, a recent analysis[79] indicates that extension in the high Tibetan Plateau cannot be explained by crustal thickening and elevated topography alone. For this extension to occur concomitant with continued collision and convergence, an additional force must be added to the system, such as a buoyancy force derived from a 'deblobbing' or delamination of thickened dense mantle lithosphere.

The contrast in stress patterns between the regionally high western US Cordillera and the 'midplate' region of North America suggests that the effects of Pacific–North American plate interaction are not transmitted through the western United States. The source of much of the uplift in the western United States must be thermal (or equivalently, thinned mantle lithosphere), as crustal thickness in much of this region is comparable to or less than that in the eastern United States[80]. Details of the western United States stress pattern have been discussed elsewhere[24,25,28,81]; however, it is of interest that throughout much of this elevated region the stress regime is extensional. In some cases, abrupt 90° changes in extension direction occur which appear to correlate with lateral changes in lithosphere thickness[11,28] and thermal regime[82].

Focal mechanisms within the African plate[83] show dominantly normal faulting within the thermally elevated East African rift system; events outside the rift have both strike-slip and normal faulting mechanisms. In southern Africa, overcoring measurements made in deep mines (up to 3 km depth)[63] and focal mechanisms suggest a distinct stress regime with a ~90° rotation of S_{Hmax} relative to the East African rift (Fig. 2). The general extensional stress state throughout much of the African plate is inconsistent with a compressional midplate stress field predicted solely from the plate-boundary forces (ridge push from ridges on three sides of the plate and a continental collision along the northern boundary)[19]. Furthermore, drag forces on this plate are probably minimal because Africa is moving so slowly in an absolute reference frame[65]. The profound intraplate extension in East Africa suggests an additional source of stress, probably related to buoyancy associated with mantle upwelling and lithospheric thinning

Conclusions and future work

The data and brief interpretations presented here represent a progress report intended to stimulate further interest and participation in the World Stress Map project. Analysis of the data compiled to date, together with the results of a large number of earlier regional studies, permit the following generalizations and conclusions:

- The various stress measurement and analysis techniques used in this study seem to sample contemporary regional stress orientations and show an excellent agreement despite the wide range of depths sampled.
- The state of stress throughout the upper, brittle crust is regionally consistent. This allows the definition of provinces of relatively constant orientations and relative magnitude of stress.
- Most intraplate or midplate regions are characterized by a compressional stress regime, that is, thrust or strike-slip faulting. Extensional stress regimes occur almost exclusively in anomalously high, and often thermally elevated regions, implying superposition of a buoyancy force fundamentally linked to the source of the elevation.
- A strong positive correlation between absolute plate velocity and S_{Hmax} direction for broad regions of several plates implies that the net plate-boundary forces responsible for moving these plates dominate the stress distribution in the plate interior. Evaluation of the relative importance of drag at the base of the plates will require detailed modelling constrained by data on absolute stress magnitudes.
- Local crustal structure, rheology and strength contrasts can strongly influence tectonic-stress orientations. Examples include stress rotation within a ~250-km-wide zone straddling the San Andreas fault and along continental margins.

We have several clear objectives for the future. First, we are currently cooperating with industry to obtain additional well-bore breakout data to fill in many of the gaps in the map; targeted areas include South America, Africa, the Middle East and south-east Asia. The oceans, which cover 70–75% of the Earth's surface, are greatly undersampled. Breakout analyses in two Deep Sea Drilling Project holes[84] confirmed the mean S_{Hmax} orientation inferred from nearby focal mechanisms, and established the feasibility of this stress-measurement technique in future Ocean Drilling Program holes. The oceanic data are essential for testing the preliminary observation of an approximately 90° rotation in S_{Hmax} between the younger and older portions of the Pacific plate and to constrain the magnitudes of stresses acting on this, the fastest moving, plate.

Second, to understand fully the origins of lithospheric stresses, we must constrain both stress orientations and magnitudes. Hydraulic-fracturing stress-magnitude measurements in a limited number of deep holes (in both the continents and oceans) are clearly needed to understand the stress-boundary conditions on the plates as well as to constrain the stress levels required for intraplate deformation.

Once information on both stress orientation and magnitude becomes available, detailed modelling will be possible of the various sources of stress acting on different plates. Such models, when sufficiently constrained by data, should lead to a greatly improved understanding of plate-tectonic processes. □

† Department of Biochemistry, University of Iowa College of Medicine, Iowa City, Iowa 52242, USA

The TATA sequence-binding factor TFIID plays a central role both in promoter activation by RNA polymerase II and other common initiation factors, and in promoter regulation by gene-specific factors. The sequence of yeast TFIID, which seems to be encoded by a single gene, contains interesting structural motifs that are possibly involved in these functions, and is similar to sequences of bacterial sigma factors.

THE activation and regulation of promoters of protein-coding genes is mediated both by gene-specific factors that usually recognize specific DNA-sequence elements (see refs 1–3 for reviews), and by general initiation factors which interact with common core-promoter elements (see refs 4–8). The most common core-promoter element is the TATA sequence (or TATA box) (see refs 4 and 9) and an interacting transcription initiation factor, designated TFIID (ref. 10), has been identified in *Drosophila*[11], mammals[4,12] and yeast[13–15]. The binding of TFIID represents the first step in core-promoter activation[4] and in turn facilitates stepwise interactions of RNA polymerase II and other general initiation factors[5–8]. Consistent with its capacity for template commitment[16–18], TFIID seems to remain bound following initiation and promoter clearance[5], and may catalyse multiple rounds of initiation

In principle, any of the steps and factors involved in core-promoter activation are potential targets for the action of regulatory factors. Studies in yeast indicate that there are regulatory factor interactions with RNA polymerase II[19,20]. Our previous studies (see ref. 15 for review) indicate that mammalian TFIID can be a direct target for both cellular and viral activators[6,12,21–23], and that stable binding of TFIID to the promoter can preclude repression mediated by chromatin assembly[23,24]. Thus TFIID has a central role in transcriptional regulation because it both recruits other general factors to the promoter and serves as a target for regulatory factors. The importance of understanding the structure and function of TFIID has been emphasized by suggestions of the presence of functionally distinct TATA elements[25,26], which could be recognized by distinct factors.

The recent identification[13,14] and complete purification[15] of a yeast TATA box-binding protein that can substitute functionally for human TFIID provides an important breakthrough for investigations of the structure and function of TFIID in eukaryotes. Here we report the cloning and structural analysis of a yeast gene that encodes a functional TFIID.

Cloning of the gene that encodes TFIID

N-terminal amino-acid sequences were obtained from yeast TFIID purified by HPLC (ref. 15) and two cyanogen bromide (CNBr)-derived peptides. Sequence amplification of yeast DNA mediated by the polymerase chain reaction (PCR), with primers based on these N-terminal sequences, yielded a single 656-base pair (bp) fragment, which contained the expected sequences in the same reading frame (Fig. 1). A yeast genomic library was screened with this fragment, and one of the positive clones (YCp2D) was found to contain an 8-kilobase pair (kb) DNA insert with all of the sequences encoding TFIID that were present in the subcloned PCR fragment. The sequence of a 1,140-bp segment containing these sequences (Fig. 1) showed a single long open reading frame (ORF) encoding a 240-amino-acid protein of calculated relative molecular mass (M_r) 26,986. This value compares favourably with M_r estimates of purified TFIID[15] obtained from SDS-PAGE (M_r, 27,000) and Sephacryl S-300 gel filtration (M_r, 28,000). The region of YCp2D that was sequenced contained all of the natural TFIID-derived peptide sequences in the long ORF (arrows and underlined regions in Fig. 1), as well as a TATA box (data not shown) and an AATAAA polyadenylation signal (boxed in Fig. 1).

TFIID messenger RNA and chromosomal DNA

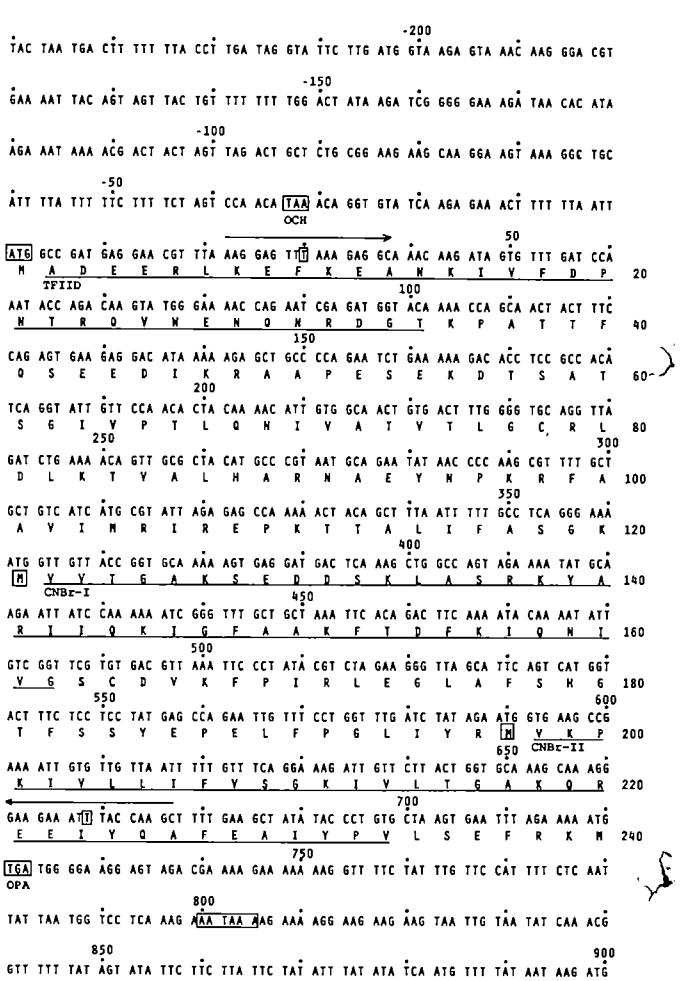
RNA blot analysis with the TFIID-DNA probe (Fig. 2*a*) revealed a discrete RNA species of ~1,100 nucleotides which was greatly enriched in the poly (A)-selected RNA and undetectable in the poly(A)$^-$ fraction. Similarly, primer extension analysis (Fig. 2*b*) detected one main 5′ end, which was ~190 bp upstream of the initiation methionine (boxed ATG in Fig. 1) and ~70 bp downstream of the TATA element (data not shown). Thus, TFIID mRNA consists of a single main species with a long 5′ untranslated region. Although post-transcriptional control has been observed for other yeast mRNAs with long 5′ untranslated regions[27], these RNAs, unlike TFIID mRNA, also contained short ORFs in the untranslated regions.

To investigate the copy number of the gene that encodes TFIID, genomic DNA was digested with each of three restriction endonucleases and blots of resolved fragments were probed with the PCR-derived insert from the plasmid vector pGEM7-2D (Fig. 2*c*). Consistent with the presence of only two *Rsa*I sites in the coding sequence and no *Eco*R1 and *Hin*dIII sites in the sequenced region of YCp2D (Fig. 1), digestion with these enzymes gave single hybridizing bands of 441 bp, ~2.5 kb, and ~7 kb, respectively (Fig. 2*c*). Although these analyses were performed under high-stringency hybridization conditions, similar analyses under low-stringency conditions failed to reveal additional bands. Altogether, these data indicate that there is only one gene that encodes the isolated TFIID; this gene has been mapped to chromosome 5 (D. Poon, unpublished results). Preliminary results from gene-disruption experiments (data not shown) indicate that this gene is essential.

In vitro expression of a functional TFIID

Sequences extending from nucleotides −223 to +723 relative to the translation start site (Fig. 1) on the YCp2D insert were cloned into the plasmid vector pRS315, and the resulting plasmid (pRS315-2D) was transcribed by phage T7 RNA polymerase.

Translation of these RNAs in a reticulocyte lysate led to the production (Fig. 3*a*) of a polypeptide with an M_r of 27,000 (p27), equivalent in size to purified TFIID[15]. Mobility shift assays with these same lysates also showed site-specific binding of the translated p27 to the adenovirus major late promoter; the complex that was formed had the same mobility as that generated with purified TFIID, and showed the same relative sensitivity to oligonucleotide competitors containing intact versus mutated TATA sequences (Fig. 3*b*). In addition, as previously reported for the natural yeast TFIID[13-15], the expressed p27 could substitute for human TFIID in stimulating transcription from the adenovirus major late promoter. As shown in Fig. 3*c*, lysates programmed with pRS315-2D transcripts complemented endogenous TFIID-depleted HeLa-cell extracts (lanes 12–15), as did human TFIID (lanes 2–3), whereas lysates programmed with no RNA (lanes 4–7) or with brome mosaic virus RNA (lanes 8–11) showed no TFIID activity. These results provided convincing evidence that the cloned YCp2D insert encoded a polypeptide of M_r 27,000 with TATA box-binding- and transcription initiation activities (TFIID).



Sequence alignments and structural motifs

Analysis of the sequence of the gene that encodes TFIID (Fig. 1) failed to show any of the highly conserved motifs (zinc fingers, helix-turn-helix motifs, or leucine zippers) that are characteristic of many other sequence-specific DNA-binding proteins (see ref. 3 for a review). Computer searches of the EMBL and GENBANK data bases also failed to detect any genes with extensive sequence similarities to the gene for TFIID. One of the many proteins with weak sequence similarities to TFIID was the adenovirus EIIA single-stranded DNA-binding protein[28] (23% identity and 37% similarity over 132 residues); this is consistent with the single-stranded DNA-binding activity of TFIID[4] and the likelihood of promoter melting during initiation[29].

Given the functional similarities between TFIID and bacterial sigma factors[29], which include the ability to recognize TATA or TATA-like promoter elements, we made comparisons of their corresponding sequences (Fig. 4*a*). The sequence alignments were most extensive for the *Bacillus subtilis* phage SPO1-specific σ-factor spoIIAC (27% identity and 47% similarity over 30 residues), and less extensive for the primary sigma factors σ^{70} and σ^{43} (23% identity and 40% similarity over the same region). For each σ-factor, the region of greatest similarity contained part of the σ-factor 2.3 region (positions 1–18 in Fig. 4*a*), which has been suggested to be involved in single-stranded DNA binding[29], and all of the σ-factor 2.4 region (positions 19–42), implicated directly in interactions with the −10 consensus element (TATAAT consensus) of prokaryotic promoters[29-31]. Like the σ-factor 2.3 regions[23], the TFIID region between residues 167 and 196 contains a high density of aromatic (and some basic) residues. Additionally, we have noted alternative sequence alignments between two regions that follow the aromatic-rich region of TFIID and part of the σ-factor 2.4 region

FIG 1 Nucleotide sequence of the *S cerevisiae* gene that encodes TFIID. Amino-acid sequences matching those determined for the N-terminal regions of natural TFIID and CNBr-derived polypeptides (I and II) are underlined Primer DNA sequences used in the PCR cloning are marked by arrows Translation start and stop codons, methionine residues N-terminal to CNBr-I and -II, and potential polyadenylation signal sequences are in boxes Single nucleotides in boxes (residues 30 and 669) denote positions that differ in the PCR-derived clone, whether this reflects mismatch hybridization of degenerate primers or sequence variations in different yeast strains used for DNA cloning is unknown, but the variations do not affect the amino-acid sequence

METHODS. From 30 μg of an SP-Sepharose fraction[15], reverse-phase HPLC-purified TFIID and two derived CNBr polypeptides (I and II) were obtained and sequenced as previously described[15,36]. These sequences in the single-letter amino-acid code, with uncertain residues indicated by X or in parentheses, were TFIID, NH_2-ADEERLKEFKEANKIVFDPNTRQVXENQN(R)-(D)(G)(T/I)-COOH, CNBr-I, NH_2-VVTGAKSEDDSKLASRKYARIIQX(K/I)-(G)F(S/A)(A/K)(D/K)(F)(T)(D)(F)(K)(I/S/R)(Q)(N)(I)(V)G-COOH, CNBr-II, NH_2-VKPKIVLLIFVSGKIVLTGAKQREEIYQAF(E)(A)(I)(Y)(P)(V)-COOH For the PCR, the sense primer based on TFIID N-terminal residues 7–12 (KEFKEA) was 5′-ATATGAATTCAA(A/G)GA(A/G)TT(C/T)AA(A/G)GA(A/G)GC-3′ and the antisense primer based on CNBr-II residues 24–29 (EEIYQAF) was 3′-CT(C/T)CT(C/T)TA(A/G/T)AT(A/G)GT(C/T)CGTTCGAAATTA-5′ The initial 10 nucleotides (underlined) in each oligonucleotide were included to generate restriction-endonuclease cleavage sites, although they were not used subsequently Each primer (1 μg) and either 0 1 or 1.0 μg of either *S cerevisiae* genomic DNA or total DNA of the YCp-based genomic library[37] template was boiled for 5 min and cooled slowly to 30 °C After addition of nucleoside triphosphates (0 2 mM) and Taq polymerase (2 5 u) the reaction was subjected to cycles of 1 min at 94 °C, 2 min at 55 °C and 3 min at 72 °C in a Perkin-Elmer machine After 50 cycles, the temperature was gradually decreased over 20 min to 24 °C and the final sample stored at 4 °C Under these conditions the size and amount of the amplified DNA was independent of the DNA source or the amount of template DNA, and generated a single fragment that was cloned into pGEM7 Sequence analysis of the resulting plasmid (pGEM7-2D) showed a 656-bp insert with TFIID N-terminal residues 7–33, CNBr-I residues 1–41, and CNBr-II residues 1–29 in the same reading frame The excised insert was labelled by nick translation and used to screen about 100,000 bacterial colonies from a YCp-based genomic library[37] by standard techniques After hybridization, filters were subjected to three 10-min washes at room temperature in 2×SSC, 0 1% SDS, and to one 15-min wash at 60 °C in 0 2×SSC and 0.1% SDS before autoradiography Two additional screens by the same procedure yielded 10 positive clones The partial sequence of the clone (YCp2D) with the largest insert (~8 kb) is shown.

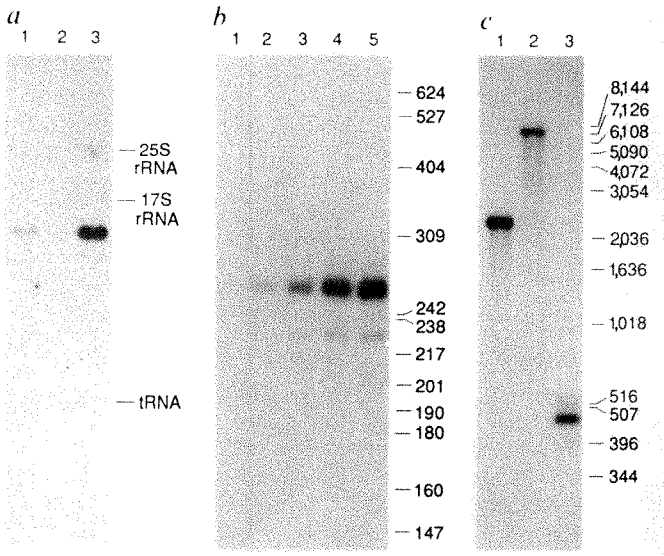


FIG. 2 Mapping of mRNA and genomic DNA. *a*, Northern blot of 20 μg total RNA (lane 1), poly(A)$^-$ RNA (lane 2) and poly(A)$^+$ RNA (lane 3). The positions of size markers (~ 3,700, 2,200 and 100 nt) are indicated. *b*, Primer extension analysis of poly(A)$^+$ RNA (0, 2, 5, 10 and 20 μg in lanes 1–5) with size markers indicated. *c*, Southern blot anlaysis of genomic DNA digested with *Eco*RI, *Hin*dIII and *Rsa*I (lanes 1–3) with size markers shown.
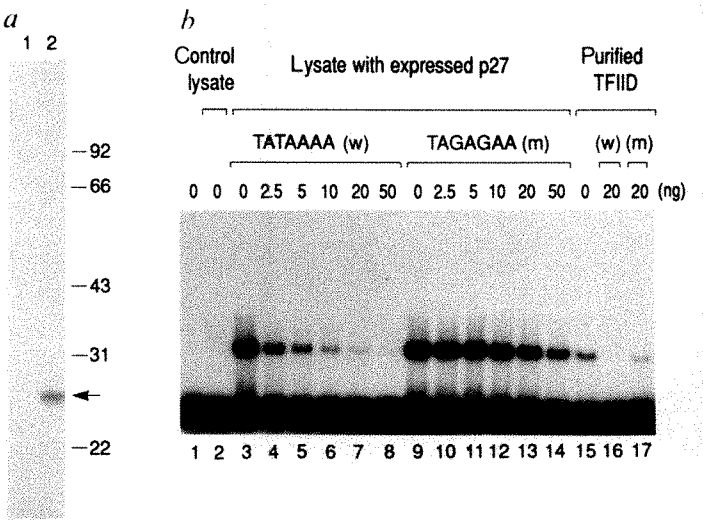
METHODS. Total RNA from *S. cerevisiae* strain BJ926 (grown to late log phase in yeast-extract peptone dextrose) was fractionated into poly(A)$^-$ and poly(A)$^+$ fractions by oligo(dT)-cellulose chromatography. For the northern analysis (*a*), RNA samples were fractionated on 1.5% agarose gels containing 2 M formaldehyde, transferred to nitrocellulose paper (Schleicher and Scheull BA85), UV-crosslinked and probed with a random primer-labelled *Hin*dIII insert (nucleotides 122–1616) from pGEM7-2D. Blots were washed twice for 30 min at 65 °C in 2 × SSPE–0.1% SDS, and twice for 15 min at 65 °C in 0.2 × SSPE–0.1% SDS before autoradiography. Ethidium bromide staining of the agarose gel indicated complete transfer of 17S- and smaller RNAs. Primer-extension mapping of the 5′ end (*b*) used a 5′ end-labelled oligonucleotide complementary to nucleotides +34 to +63 (Fig. 1), and resolution on a standard 10% polyacrylamide–urea sequencing gel before autoradiography. For the Southern blot (*c*), 1 μg samples of genomic DNA were digested with the indicated enzymes, fractionated in 0.8% (w/v) agarose gels, depurinated, transferred to nitrocellulose membranes and probed with labelled fragments used for the northern blot. Blots were subjected to four 10-min washes in 2 × SSC and 0.1% SDS at 20 °C, and four 30-min washes in 0.1 × SSC and 0.1%SDS at 50 °C before autoradiography. Unless otherwise noted, standard procedures were used. Size markers were yeast ribosomal (r)- and transfer (t) RNAs (*a*), *Hpa*II-digested pBR322 fragments (*b*) and BRL 1-kb markers (*c*).



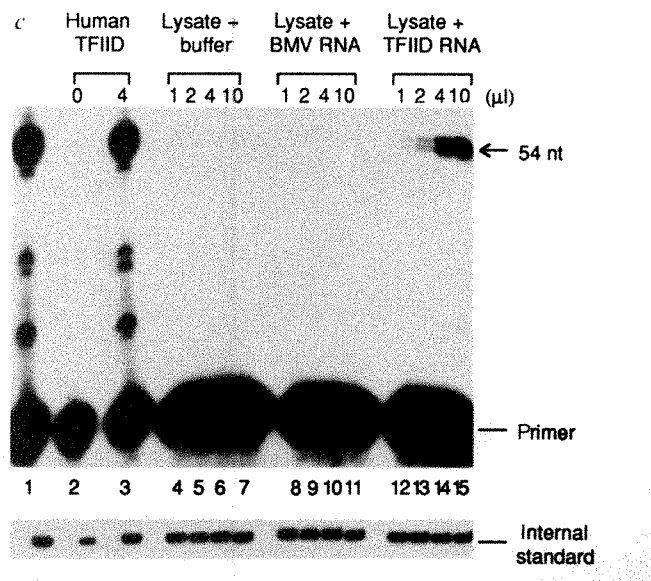


FIG. 3 Expression and function of cloned yeast TFIID. *a*, SDS-PAGE analysis of [^{35}S]methionine-labelled TFIID expressed in a reticulocyte lysate. Lysates were programmed with no RNA (lane 1) or cloned TFIID-derived mRNA (lane 2). *b*, Site-specific DNA binding of expressed yeast TFIID. Electrophoretic mobility shift assays with an adenovirus major late promoter (MLP) fragment contained: lane 1, no protein; lane 2, lysate programmed with brome mosaic virus (BMV) RNA (negative control); lanes 3–14, lysate programmed with TFIID mRNA; lanes 15–17, purified yeast TFIID. Competing oligonucleotides (MLP; positions −45 to −15) contained either wild type (w)- or mutant (m) TATA sequences (as indicated at the top) and were added in the nanogram amounts indicated at the top of each lane. The arrow indicates the specific protein–DNA complex. *c*, Transcription activation by expressed TFIID. Transcription from the adenovirus MLP was measured in a complete HeLa-cell nuclear extract (lane 1) or in a TFIID-depleted nuclear extract[4] complemented with (1) buffer only (lane 2), (2) human TFIID (lane 3) or (3) increasing amounts (1, 2, 4 and 10 μl) of reticulocyte lysate programmed with buffer (lanes 4–7) or BMV RNA (lanes 8–11) or RNA transcribed from the cloned yeast TFIID gene (lanes 12–15). Specific transcripts are indicated by the 54-nucleotide (nt) band.
METHODS. A phage T7 RNA polymerase-driven expression plasmid (pRS315-2D) containing sequences of the gene for TFIID from −223 to +723 was constructed as follows. We synthesized one oligonucleotide (5′-GGCCGGCCCGAGCTCACCTTGATAGGTATTCTTGA-3′) with sequences (underlined) complementary to 5′ sequences of the gene for TFIID and with a *Sac*I recognition site (GAGCTC) 9 nt from the 5′ end. A second oligonucleotide (5′-GGGCCGCCGGCTGCAGTTACTATCACATTTTTCTAAATTCACT-3′) was synthesized, with sequences (underlined) complementary to 3′ sequences of the gene for TFIID and with a *Pst*I recognition site (CTGCAG) 10 nucleotides from the 5′ end followed immediately by two additional in-frame translation stop signals (UAA and UAG). These two oligonucleotides were used to amplify sequences of the gene encoding TFIID using the PCR conditions described in Fig. 1. The *Sac*I–*Pst*I fragment was cloned into pRS315[38] by means of the *Sac*I and *Pst*I sites, and one plasmid (pRS315-2D) was sequenced to verify that the coding region and translation signals were intact. The plasmid was transcribed with phage T7 RNA polymerase and amounts (1 μg) of purified RNA used to template reticulocyte lysates (Promega). Translation products were either analysed by SDS-PAGE (after [^{35}S] methionine labelling) (*a*) or employed for site-specific binding (*b*) and functional (*c*) assays. Mobility shift assays used either 0.5 μl lysate or 0.4 ng purified yeast TFIID and an end-labelled fragment extending from positions −138 to +46 of the Ad MLP. Conditions were as previously described[15], except that reactions also contained 20 ng poly(dG–dC). Transcription assays used untreated HeLa-cell nuclear extracts or HeLa-cell extracts in which endogenous TFIID was inactivated by a 15-min incubation at 47 °C (ref. 4), an intact plasmid template (pSmaF) containing the adenovirus MLP, and either partially purified human TFIID[4] or reticulocyte lysate programmed with TFIID mRNA. Specifically initiated adenovirus MLP transcripts were monitored by reverse-transcriptase extension of a 30-nucleotide primer complementary to nucleotides +25 to +54.

(Fig. 4*a*, bottom). These alignments emphasize highly conserved hydrophobic residues at every fourth position, followed by position-specific basic residues[31].

Yeast TFIID has a net positive charge (pI = 9.84) with a central region (Fig. 4*b*) rich in basic (especially lysine) residues. The central part of the proline-free region between residues 110 and 168 has a high potential for α-helix formation (data not shown), and the entire array of basic residues in this region could be on the same face of an α-helix (Fig. 4*c*, *d*). Both the central core of five basic residues and the repeat pattern of some of the lysines (at 7- and 11-, or at 18-residue intervals) may be important for this region. Possible functions for this region are discussed below.

Discussion

In this report we have described the cloning of a yeast gene that encodes TFIID. This gene is transcribed to give a discrete unspliced mRNA. Our confirmation that active yeast TFIID is a monomeric (apparently unprocessed) protein of M_r 27,000 leads to the suggestion that the functionally interchangeable human factor, which appears to be much larger [32,33] and binds to an extended region on the promoter[4], is either heteromeric or consists of a larger polypeptide possibly possessing additional functional domains (for example, regulatory domains). Related to this point is whether the yeast factor is capable of mediating all the regulatory factor interactions that are mediated by human TFIID. Our recent studies (with E. Sinn, unpublished results) have indicated that yeast TFIID can mediate herpesvirus (pseudorabies) IE-dependent transcription *in vitro*.

The central role of TFIID in promoter activation and regulation necessitates several separate or overlapping structural domains, which include those for DNA binding, interactions with basic factors, and interactions with regulatory factors. Therefore it might be expected that there is an overall TFIID structure that is distinct from, and less flexible than, those of the DNA-sequence-specific activators described so far. Consistent with this is the failure of computer searches to reveal structural motifs in TFIID that are commonly found in many other DNA-binding domains, or strong sequence similarities (homologies) between TFIID and other proteins involved in nucleic acid function.

More direct sequence comparisons have shown weak sequence similarities of regions of TFIID with conserved regions of bacterial σ-factors. This is of interest because there are general functional similarities between TFIID and σ-factors in directing core-promoter recognition by corresponding RNA polymerases (along with other factors in eukaryotes), and because similar sequence elements are recognized during these processes. Thus TFIID interacts most strongly with an element (consensus sequence TATAAA) that resembles the common −10 consensus sequence TATAAT of many bacterial promoters. The general similarity between a region of TFIID and the aromatic rich σ-factor 2.3 region is of potential interest, because the σ-factor may recognize single-stranded DNA when the −10 consensus is melted in the bacterial pre-initiation complex[29] and because of expectations that eukaryotic TATA-initiation-site regions may also be melted during initiation. The more extensive similarities between TFIID and σ-factor 2.4 regions are interesting because of the genetic evidence for direct contacts between the σ-factor 2.4 region and the −10 promoter region. Internal deletions in the σ-factor-related region of TFIID eliminate the ability of TFIID to bind to the TATA box (T. Yamamoto, unpublished results), consistent with this region being involved in promoter binding. Future studies will determine whether the sequence similarities are of significance and whether any of the other general functions of σ-factors are retained in TFIID. Although highly conserved regions of σ-factors have been implicated in core RNA polymerase interactions[29], the observation[5–7] that promoter recognition by RNA polymerase II requires factors in addition to TFIID indicates that TFIID may not contain a similar domain.

Also of interest is the potential distribution in TFIID, along one face of an α-helix, of a central cluster of basic residues that includes a short Arg-Lys repeat and a longer Lys repeat. The probability of this region being involved in DNA recognition is raised by the recent implication of basic domains in such

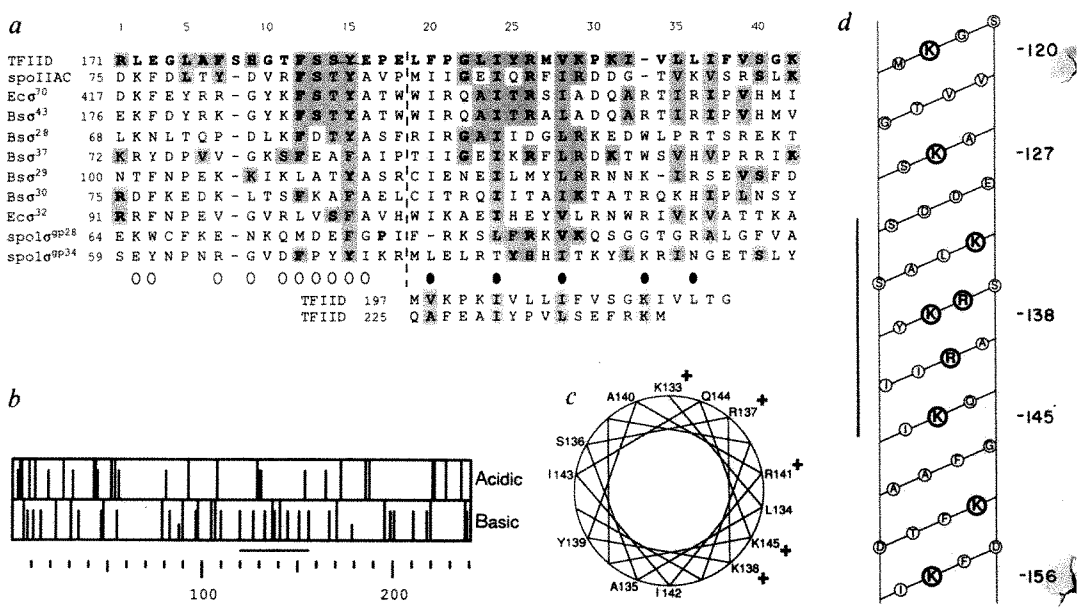

FIG. 4 Structural features of yeast TFIID. *a*, Alignment of TFIID sequence with bacterial σ-factor sequences (single-letter amino-acid code). *Escherichia coli* (Ec), *B. subtilis* (Bs) and bacteriophage SPO1 (spo1) σ-factor sequences are from refs 29 and 31. The position in the protein sequence of the first residue in each line is indicated in the second column. Amino acids identical to those in TFIID are in bold and conserved amino acids (relative to the TFIID sequence) are shaded according to the groupings (K, R, H), (E, D), (N, Q), (G, P), (A, I, L, V), (F, W, Y), (M, C), and (S, T). The open circles indicate the conserved positions in the σ-factor 2.3 domain (left of dashed line), whereas the solid circles denote only those positions in the σ-factor 2.4 domain (right of dashed line) that are most highly conserved[31] in all the σ-factors. The shaded areas in the lower two lines show those TFIID residues that match the most conserved σ-factor 2.4 region residues. *b*, Positions of acidic and basic residues in TFIID. Short bars, D or K, tall bars, E or R. *c*, Helical wheel depiction of TFIID residues 133–145. *d*, Flattened helix display of TFIID residues 118–157 (region underlined in *b*), with basic residues in bold. The helix was flattened (see ref. 34) by splitting it lengthwise along the face opposite to the aligned lysines at positions 120, 127, 138, 145 and 156. The split residues at positions 136 and 154 are shown in duplicate. The vertical bar on the left side indicates the region depicted in *c*.

functions[34]. Alternatively this region could interact with specific domains in other transcription factors, such as the acidic domains of upstream activators (see ref. 2 for a review) or the phosphorylated C-terminal repeat of the largest RNA polymerase II subunit (see ref. 35 for a review). The amphipathic nature of some activating domains[2], such as those in GAL4 and GAL4 derivatives, make this interaction model more likely; indeed a direct effect of GAL4 derivatives on mammalian TFIID-promoter interactions has been demonstrated[21]. The presence in TFIID of repeated structures might also allow simultaneous, synergistic interactions of multiple activators[2]. Alternatively, activators could also interact with other components of the basic transcription machinery.

Given functionally distinct σ-factors in prokaryotes[29] and reports of functionally distinct TATA elements in eukaryotes[25,26], the idea of multiple TATA-binding factors in eukaryotes is appealing. Although we detected only a single essential gene that encodes the predominant form of TFIID in *Saccharomyces cerevisiae*, our studies do not eliminate the possibility of multiple, perhaps more distantly related, genes that encode factors with similar functions. Could TFIID be thus involved in the transcription from promoters that do not have TATA elements? Human TFIID can interact not only with the TATA element but also with DNA sequences around and downstream of the initiation site[4,12], with other general factors[5-7] and with upstream factors[6,12,21]. The combined effects of these interactions could therefore serve to stabilize TFIID in a pre-initiation complex, and allow its normal function, even in the absence of strong TATA element interactions. The availability of a homogenous yeast TFIID, along with the appropriate genetic analyses in yeast, should allow these ideas to be tested. □

MyoD1 and myogenin are muscle-specific proteins which can convert non-myogenic cells in culture to differentiated muscle fibres, implicating them in myogenic determination. The pattern of expression of MyoD1 and myogenin during the early stages of muscle formation in the mouse embryo *in vivo* and in limb-bud explants cultured *in vitro*, indicates that they may have different functions in different types of muscle during development.

MYOGENIC cell lines and primary cultures of myoblasts from muscle tissue undergo many of the steps characteristic of terminal myogenic differentiation *in vivo*. These steps include cell fusion to form multinucleated myotubes and the accumulation of muscle-specific transcripts and their products[1]. Thus, the transition of myoblasts to myotubes provides a useful system for the study of myogenesis, in particular the regulation of genes that encode muscle structural proteins and enzymes.

Until recently, regulatory steps which precede terminal differentiation have been less accessible to investigation. We have previously isolated two complementary DNA sequences for MyoD1[2,3] and myogenin[4], which seem to have a role in myogenic determination and differentiation; non-muscle cells transfected with these sequences can be converted to the myogenic pathway. Data obtained from cultured muscle-cell lines indicate that MyoD1, which may be constitutively expressed in myoblasts, should appear earlier during develop-

ment than myogenin, which is expressed during myoblast terminal differentiation. Northern blot analysis of isolated tissues has shown that the transcripts for MyoD1 and myogenin are specific to skeletal muscle during late fetal, newborn and adult stages[2,4]. We have now examined the expression of these two transcripts during embryogenesis to ascertain whether myogenesis *in vivo* involves the same factors as those isolated from cell lines.

We localized the myogenin and MyoD1 transcripts *in situ* in tissue sections of mouse embryos and in limb bud explants cultivated *in vitro*. Myogenin transcripts were first detected in the myotomal cells of the first somites, whereas MyoD1 transcripts began to accumulate ~2 days later. By contrast, MyoD1 and myogenin transcripts became detectable during limb development at the same time. These observations indicate that distinct populations of myogenic precursor cells exist in the embryo, which differ in their pattern of expression of MyoD1 and myogenin. Although all the cells present in the limb bud explant were initially negative for myogenin and MyoD1, positive cells subsequently appeared and the initial stages of muscle formation took place as *in vivo*. Because all limb musculature in vertebrates is probably derived from cells in the somites, these experiments indicate that an earlier myogenic precursor cell is present, which does not contain detectable levels of myogenin or MyoD1.

Myogenin and MyoD1 expression in the somites

Myogenin transcripts were first detected at ~8.5 days *post coitum* (p.c.) in the myotome compartment of the somites, and were expressed at high levels by 9.25 days p.c. (Fig. 1*a*, *b*). The onset

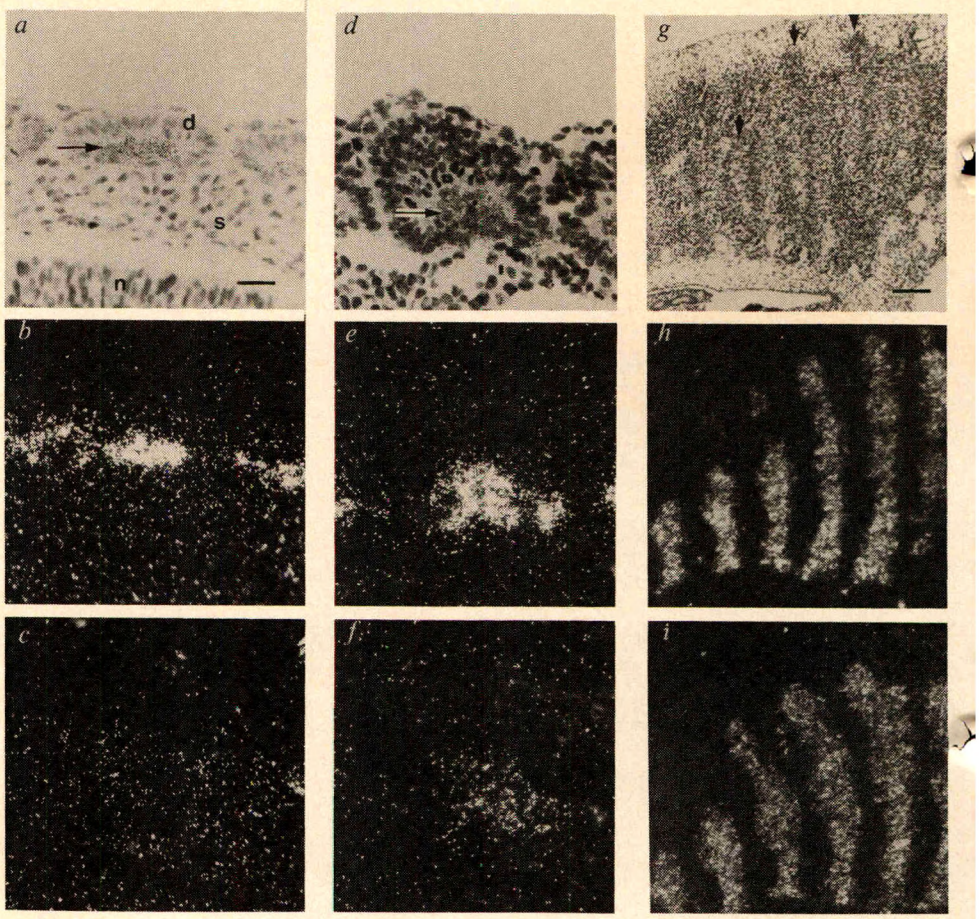

FIG. 1 *a–c*, Expression of myogenin and MyoD1 in somites of a 9.25-day-p.c. (24 somites) mouse embryo. *a*, Photomicrograph of two caudal somites from a 9.25-day-p.c. mouse embryo, cut sagittally. This section was hybridized with a cRNA probe for myogenin mRNA and even under light-field optics intense silver-grain accumulation was observed over the myotomal (indicated by an arrow) by a compartment S sclerotome; d, dermotome; n, neural tube. *b*, Darkfield photomicrograph of section shown in *a*. Close-to-saturating grain densities were observed for myogenin. At this stage, detection of myogenin was restricted to the somites, predominantly over the myotomal portion. *c*, Darkfield photomicrograph of a section immediately adjacent to that in *a* and *b*. This section was hybridized with a probe for MyoD1 mRNA. No accumulation of grains was detected, indicating that transcripts for MyoD1 were either absent or present in very low quantities. Section thickness, 1.0 μm. *d–f*, Expression of myogenin and MyoD1 in somites of a 10.5-day-p.c. mouse embryo. *d*, Photomicrograph of rostral somites. This section has been hybridized with a cRNA probe for myogenin mRNA, and silver-grain accumulation was observed over the myotomal compartment (arrow) *e*, Darkfield photomicrograph of section in *d*. At this stage, detection of myogenin was still restricted to the somites. *f*, Darkfield photomicrograph of a section immediately adjacent to that in *d* and *e*. This section was hybridized with a probe for MyoD1 mRNA. A light accumulation of grains was detected indicating that transcripts for MyoD1 were present. Section thickness, 5–7 μm. *g–i*, Expression of myogenin and MyoD1 in myotomes of an 11.5-day-p.c. mouse embryo. *g*, Lightfield photomicrograph of rostral myotomes showing muscle masses (arrows) in between sclerotomal (precostal) tissue. *h*, Same section as in *g*, viewed with darkfield optics showing myogenin expression in myotomal masses. *i*, Adjacent section viewed with darkfield optics hybridized with MyoD1. Labelling is more dispersed but of equal intensity to that for myogenin at this stage. Section thickness, 5–7 μm. Scale bars: *a–f*, 50 μm; *g–i*, 150 μm.

METHODS. Preparation of probes: A cDNA corresponding to myogenin was subcloned into a Bluescribe M13$^-$ (Vector cloning Systems). The cRNA transcripts were synthesized according to manufacturer's conditions and labelled with ^{35}S-labelled UTP (>1000 Ci mmol^{-1}; NEN). Linearization with *Pst*I followed by transcription with T7, yielded a cRNA corresponding to the terminal 700 nucleotides of the cDNA, which is specific for myogenin transcripts and which does not contain regions homologous to MyoD1 transcripts, including the c-*myc*-like region[4]. The cRNA transcripts were subjected to alkali hydrolysis[5] to give a mean size of 60 bases for efficient hybridization. A cDNA corresponding to MyoD1 was subcloned into a Henikoff-modified Bluescribe vector and linearized with *Mlu*I to give an antisense probe corresponding to the 3′ part of the cDNA, from nucleotides 751 to 1,785 (see ref. 2). Radiolabelled transcripts were made as for myogenin. Again, the site of linearization was chosen to yield a cRNA specific for MyoD1 transcripts and which did not contain domains corresponding to the c-*myc* region. For both probes, the final concentration was adjusted to 90,000 d.p.m. μl^{-1} in hybridization buffer. Results were directly compared with our previous results using cRNA probes to the α-actins from the same embryos on adjacent tissue sections[5]. In addition, sibling or age-matched embryos were studied to ensure that all somites were represented. Cells were considered labelled if grain density was ≥5 times that of non-muscle cells. Because non-muscle cells had background levels rarely exceeding 2 grains per cell, these cells were considered as unlabelled. Procedures used for embryo preparation and subsequent histological treatment were as described previously[5]. Sections of 1 μm were obtained, by cutting cooled paraffin blocks of tissue in a cryostat (Bright Instruments), equipped with a motor drive, at −18 °C. Sections were collected on subbed slides and relaxed on a drop of distilled water-1% ethanol solution, and then treated as regular tissue sections. Embryos used for these studies were C3H and C3H×BALB/c. Embryonic development was monitored according to ref. 22. For summary of results see Table 1.

TABLE 1 Expression of myogenin and MyoD1 in mouse somites and limb buds

Embryo age	Rostral somites				Caudal somites				Limb buds (fore and hind)		
	Myogenin	MyoD1	Cardiac α-actin	MHC	Myogenin	MyoD1	Cardiac α-actin	MHC	Myogenin	MyoD1	Cardiac α-actin
8.5 days p.c. (2)	++	−	+	−							
9 days p.c. (2)	+++	−	+	−					−	−	−
9.25 days p.c. (2)	+++	−	++	−	+++	−	++	−	−	−	−
9.5 days p.c. (2)	+++	−	++	+	+++	−	++	−	−	−	−
10.5 days p.c. (4)	+++	+	++	++	+++	+	++	−	−	−	−
11.5 days p.c. (5)	+++	+++	+++	+++	+++	+++	+++	+++	++	++	++

Results are summarized from *in situ* hybridization experiments on mouse embryos with probes for myogenin, MyoD1, cardiac α-actin, and myosin heavy chain (MHC) sequences. Probes for myogenin and MyoD1 transcripts were as described in Fig. 1. Transcripts for cardiac α-actin were detected with a 5′ non-coding sequence probe specific for this messenger RNA[5]. MHC transcripts were detected with a coding-sequence probe derived from the 3′ end of the β-MHC mRNA (150 base pairs (bp), *PstI–PstI* fragment), which cross-hybridizes with the different striated-muscle MHC mRNAs present (G.L., manuscript in preparation). Hybridizations were performed on the numbers of embryos indicated in parentheses. Paraffin sections were 5–7 μm thick, except for embryos at 9.25 days which were sectioned at 1.0 μm. In general, three serial sections from two different embryos (that is, six sections) were hybridized together on the same slide with one probe. The next three sections were hybridized with a second probe, and so on. Hybridization was performed alternately with different probes to be certain that a negative result with one probe was flanked by positive results with the other, and thus was not due to the plane of section. The numbers of sections generated ranged from 50–100 per embryo. An indication of relative intensities is given; this is based on visual impression, however, and represents only an approximation of the relative levels of transcripts. The intensities reflect both density of labelling over a single cell and the number of positive cells. No indication is given here of the regional distribution of transcripts in the somite or limb bud, for example between myotomal cells and myocytes in the somite[5]. MHC expression is only seen in differentiated myocytes of the myotomal muscle. The morning of vaginal plug was counted as post-coital (p.c.) day 0.5; cardiac development and numbers of somites were followed as a further check on dating, and corrections were made on this basis. As there is an anterior–posterior developmental gradient, data for 'rostral' somites are for the most anterior somites, and 'caudal' for the most posterior somites.

of myogenin expression in the somites at 8.5 days p.c. coincided with that of cardiac α-actin and preceded detectable myosin expression (see Table 1), which implied that full differentiation to functional muscle had not occurred by then[1,5]. By contrast, detailed analysis of almost all somites present in these embryos failed to detect any significant MyoD1 signal. Two embryos (each 9.25 days p.c.; 24 somites) were serially sectioned at 1 μm, and sections were alternately hybridized with probes for either myogenin or MyoD1. In all cases where the myotomal compartment was morphologically discernible, intensely labelled myogenin transcripts were easily detectable; no significant labelling over background was observed with MyoD1, however, either in the somites (Fig. 1*c*) or elsewhere in the embryo, even after prolonged exposure times (11–14 days versus 7 days). Because of the thinness of the sections (1 μm) and the fact that almost all of the sections that were negative for MyoD1 were immediately adjacent to sections that were positive for myogenin, it was unlikely that adjacent sections did not represent comparable zones in any given somite. These results indicate that transcripts for MyoD1 are either absent or are present at very low levels in cells expressing both cardiac α-actin[5] and myogenin.

By 10.5 days p.c., the myotomes of the somites differentiate into segmented blocks of myotomal muscle[5–7]. We observed myogenin labelling throughout the myotomal compartment (Fig. 1*d*, *e*). At this stage MyoD1 began to be detectable over the somites and muscle myotomes (Fig. 1*f*). Because somitogenesis occurs in a rostral–caudal direction, myotomes first appeared at the anterior portion of the embryo, whereas less mature somites which lacked myotomal muscle were present near the tail. Both the anterior myotomal muscle and the posterior somites at this stage were positive for MyoD1. Thus, no obvious morphological change was evident that coincided with the appearance of MyoD1. By contrast, muscle myosins were expressed at this time only where myotomal muscle was forming in the rostral myotomes (see Table 1). It has been proposed[8] that an induction, possibly neural, occurs in all the somites by 10.5 days, which changes the myogenic programme of somite-derived myoblasts. The accumulation of MyoD1 transcripts correlates with this phenomenon, which may represent a change in the myogenic programme.

By 11.5 days p.c., intense labelling (both of myogenin and MyoD1) is still observed over all somite segments, including the most posterior somite. In addition, intercostal, intervertebral and various other muscle anlagen are highly positive for both probes. At 15 days p.c., all muscle masses maintain high levels of myogenin and MyoD1. The relatively 'late' appearance of MyoD1 indicates that the earliest myogenesis in the embryo (myotomal muscle) may begin in the absence of this factor. It is therefore unlikely that MyoD1 is a trigger for these early events, although its eventual presence indicates that it plays a part during subsequent stages of myotomal development. The appearance of different muscle-marker sequences that we examined during myotomal muscle formation is summarized in Table 1.

No expression of myogenin or MyoD1 was detected in non-skeletal muscle tissue in the post-implantation embryos that we examined. The heart, from the early stages of cardiac-tube formation (7.5 days) onwards, showed no expression, despite the fact that many of the contractile protein genes that are expressed in developing skeletal muscle are also expressed in cardiac muscle. This observation (see also refs 2, 3 and 4) clearly indicates that neither myogenin nor MyoD1 is necessarily a prerequisite for sarcomeric gene expression. Thus, although these proteins may activate downstream myogenic structural genes, they are strictly specific for skeletal myogenesis.

Myogenin and MyoD1 expression in the limb

Even though the forelimbs are readily distinguishable as 'limb buds' at 9 days p.c., we first detected myogenin and MyoD1 transcripts at 11.5 days p.c. in the proximal region of both the hindlimb and the forelimb. In contrast to the situation in the somites, there was no detectable asynchrony in the accumulation of the two transcripts (Fig. 2 and Table 1). At this stage, myogenin and MyoD1 were expressed in mononucleate cells, in limb tissue devoid of muscle fibres. At later stages of limb development, both the transcripts accumulated in the differentiated muscle masses (results not shown), as they did in myotomal muscle (Fig. 1*g*, *h*, *i*).

In several systems it has been demonstrated that the myoblasts that invade the developing limb bud originate from the somite (derma-myotome)[9–14]. In the mouse, a significant proportion of the mesodermal cells that will eventually contribute to the limb musculature are presumably present in the limb bud at ~9 days p.c.[14]. We tested whether the lack of detectable MyoD1-positive myoblasts in the limb bud before 11.5 days p.c. was due to an

absence of myogenic cells by removing limb buds from mouse embryos at 9.25 days p.c. (~24-somite stage) and placing them in organ culture. Such explants attach to the bottom of the culture dish in ~24 h and cells then begin to migrate out of the explant tissue. Transcripts for MyoD1 were not detectable in the limb bud or any other part of the intact embryo at the time of limb removal (9.25 days p.c.). After 4 and 5 days in culture, limb buds were analysed by *in situ* hybridization. We found strong labelling for both MyoD1 and myogenin in proximal regions of the explant (Fig. 3). These experiments indicate that the precursor cells for muscle are present in the limb and initially show no detectable expression of MyoD1 and myogenin.

Discussion

Our results clearly demonstrate that the pattern of expression of myogenin and MyoD1 in the precursor cells for myotomal muscle differs from that in the precursor cells for the musculature of the limb. Whereas MyoD1 transcripts were first detected ~2 days later than the first detection of myogenin transcripts in myotomal muscle, both transcripts appeared at the same time in the limb. This not only implies that MyoD1 and myogenin may be used differently at different developmental stages, but also indicates the existence of different populations of precursor muscle cells.

The experiments with the explanted limb bud indicate that at 9.25 days myogenic precursor cells are present which do not express either MyoD1 or myogenin. It is possible that undetectable levels of MyoD1 are present in the 9.25-day-p.c. limb and have a significant myogenic role here or in the somites. If so, the levels of transcripts are markedly lower than those seen later in development. It is also possible that cells which leave the somite and invade the limb bud are not yet determined for the myogenic lineage and thus do not express MyoD1 or myogenin. But embryological experiments indicate that all skeletal muscle in the limb is derived from the somites, and that the somites contribute to no other limb tissue[9-12]. This would mean that the cells that migrate from somites are already determined for myogenesis.

Somites present at the level of the limbs in the chick–quail chimaera system and in the mouse begin to send out cells to the limb bud just before the stage when the limb bud is discernable as a discrete structure[10]. Cells originating from a transplanted somite can be readily observed at the level of the limb bud as early as 20 h after transplantation[12]. Although the number of such cells is initially small, we would expect there to be enough to be included in the sections examined and therefore to be observed should they express either MyoD1 or myogenin. We favour the hypothesis that in the limb bud there are determined myoblasts which have not begun to express MyoD1 or myogenin. This would imply that either the cells in the somite from which they derive are negative for MyoD1 and myogenin, and that those cells that are positive in the somite are committed to myotomal rather than limb-muscle formation, or that there are cells which transiently express these factors and then cease expression as they migrate away from the somite, perhaps because of subsequent cell proliferation.

The sequences of the genes encoding MyoD1 and myogenin share a region of homology, and both are entirely specific for skeletal muscle. The genes encoding MyoD1 and myogenin are probably part of a larger gene family of regulatory factors

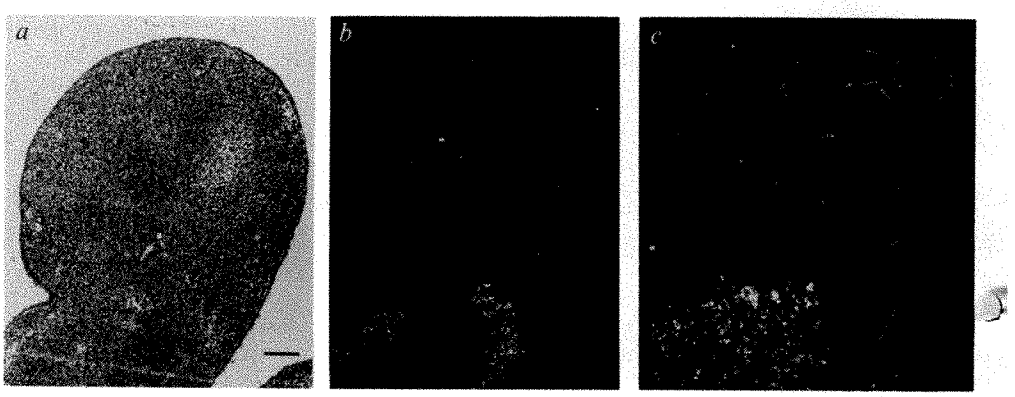

FIG. 2 Expression of MyoD1 and myogenin in the forelimb bud of a 11.5-day-p.c. embryo. *a*, Lightfield photomicrograph. Section thickness, 5–7 μm. *b*, Darkfield image of the same section hybridized with a cRNA probe for MyoD1 showing intense labelling to muscle anlagen. *c*, Darkfield image of an adjacent section hybridized with a cRNA probe for myogenin showing intense labelling to muscle anlagen. For Methods, see legend to Fig. 1 and Table 1. Scale bar, 100 μm.

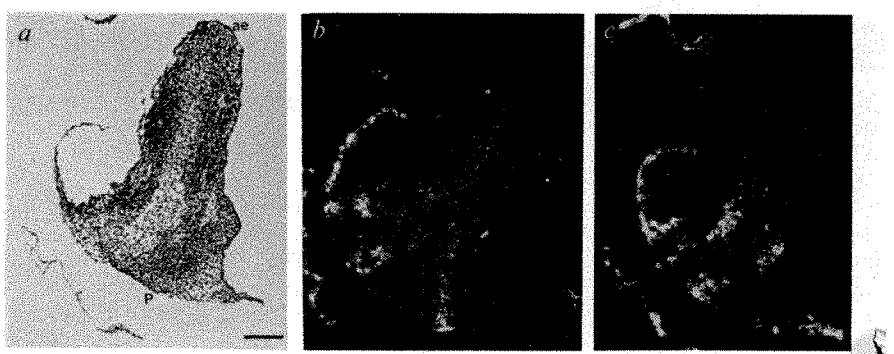

FIG. 3 Expression of myogenin and MyoD1 in a cultured embryo limb bud removed before any detectable accumulation of MyoD1 transcripts. *a*, Lightfield photomicograph of cultured limb bud showing apical ectoderm (ae) and former proximal portion of limb (P) which was attached to culture dish. *b*, Darkfield image of an adjacent section hybridized with a cRNA probe for myogenin, showing labelling in the more proximal region of the limb bud. *c*, Darkfield image of the section in *a* hybridized with a cRNA probe for MyoD1, showing labelling which is also in the more proximal region of the cultured limb bud. Scale bar, 100 μm.

METHODS. *In vitro* limb-bud explants: 9.25-day-p.c. embryos (24 somites) were removed from CO_2-anaesthetized female mice and placed in fresh, cold phosphate-buffered saline (0.13 M NaCl, 7 mM Na_2PO_4, pH 7.4). Somites were counted under a dissection microscope (Wild) and forelimb buds removed using glass and tungsten needles. The limb buds were then transferred to a 22 mm plastic culture dish (Falcon) in Dulbecco's-modified Eagle's medium (Gibco) supplemented with 10% FCS (Gibco) and 3% chick embryonic extract. Limb buds normally became anchored within 24 h, at which point the medium was replaced daily until fixation and histological preparation for *in situ* hybridization. Limb 'outgrowths' were removed from the dish with a pipette after overnight fixation in fresh 4% paraformaldehyde in phosphate-buffered saline. All subsequent steps were identical to those previously described (ref. 5; also Fig. 1 legend). At least 15-limb-bud explants were examined. Those shown were cultivated for 4 days.

involved in myogenesis; these factors may have overlapping specificities for activating downstream structural and regulatory genes for terminal differentiation. Indeed, another sequence of this kind, *myf-5*, has been isolated from human muscle tissue[15], and a potential myogenic determination factor, Myd, has also been described[16]. It has been speculated that different classes of myoblast exist throughout normal development, based on the observation that myoblast populations can be isolated which have a different behaviour in culture or express different myosin types (that is, fast versus slow myosin heavy chains[17-21]. Our observation that at least two different modes of expression exist for myogenin and MyoD1, which coincide with two different types of muscle in the embryo (earlier somite myotomal muscle compared with later-stage myotubes in the limb), indicates that these factors may have different roles in conferring muscle-type determination and differentiation during different stages of embryogenesis. □

Polarized light in high-redshift radio galaxies

HIGH-redshift radio galaxies are characterized by ultraviolet excesses[1,2] associated with elongated continuum and emission-line structures aligned along their radio axes[3,4]. Commonly, these properties are interpreted in terms of jet-induced star formation. However, observations of a blue, polarized continuum knot in the low-redshift radio galaxy PKS2152−69 have suggested an alternative beaming/scattering model[5,6]. To test this model we have obtained imaging-polarimetry observations of two high-redshift radio galaxies: 3C277.2 ($z = 0.766$) and 3C368 ($z = 1.132$). We find that both sources are strongly linearly polarized at ultraviolet rest wavelengths, with E-vectors within 25° of perpendicular to the axis of the extended continuum and radio structures. This implies that a large proportion of the ultraviolet light in these objects does not come directly from stars and we suggest it is scattered radiation from the nucleus. These observations also have important implications for beaming models of the active nuclei and for our understanding of the evolution of the host galaxies.

Ultraviolet excesses are an ubiquitous feature of high-redshift radio galaxies[1,2]. Attempts to understand this excess have centred on star formation models, although it has been difficult to explain the ultraviolet-optical and optical-infrared colours simultaneously in the framework of galaxy evolution models[2]. Recent clues to the nature of the ultraviolet excess have come from observations that show that they are associated with elongated or multi-modal continuum structures aligned along the radio axes[3,4,7,8]. This link between radio and ultraviolet structures has led to the idea that some of the star formation in the host galaxies is connected with the radio jet, perhaps induced by the passage of the jet through the interstellar medium[3,9,10]. The details of this mechanism are not well understood, however, and there is little observational evidence for such processes at low redshifts. In fact, out of the several dozen low-redshift radio galaxies that have been studied in detail only NGC541 (Minkowski's object)[11] and perhaps NGC7385[12] show any evidence of star formation associated with radio jets, and these are much lower radio power sources than those observed at high redshifts.

An alternative beaming/scattering mechanism has been suggested[5] based on observations of a high ionization cloud close to the radio axis of the low-redshift ($z = 0.0282$) radio galaxy PKS2152−69. These reveal that a continuum source within the cloud, after subtraction of the smooth stellar light from the galaxy, has both an extremely blue spectrum ($f_\nu \propto \nu^{+(3\pm1)}$) and a large linear polarization ($12 \pm 3\%$), properties that seem most consistent with a model in which the extended continuum is formed by scattering from dust of an intense beam of ultraviolet/optical radiation from the nucleus[5]. The importance of these observations to the high-redshift objects is that, if we were to observe PKS2152−69 in the ultraviolet, it would appear to have very similar properties to those observed in the high-redshift galaxies, albeit with a lower luminosity. This has lead us to propose that the elongated continuum and emission-line structures in the high-redshift objects are somewhat analogous to reflection nebulae: at least a fraction of the extended continuum represents light scattered out of the intense blazar beam by material in the cloud, whereas the emission-line regions are ionized by Lyman continuum radiation from the beam[6].

To test the beaming/scattering model we have begun a programme of imaging polarimetry of high-redshift radio galaxies using the ESO Faint Object Spectrograph and Camera (EFOSC) on the ESO 3.6-m telescope at La Silla, Chile. Using a Wollaston prism, EFOSC projects on a CCD (charge-coupled device) two perpendicularly polarized images of the field separated by 20 arcsec. A mask in the telescope focal plane with alternating opaque and transparent strips prevents object confusion and overlapping sky signal at the expense of half the field. A change of the instrumental position angle ϕ by rotating the whole EFOSC allows variation of the direction of polarization of the image pair. Further details of our imaging-polarimetry technique are given elsewhere[13] (see also Fig. 1 legend).

The two objects observed (3C277.2 and 3C368) were selected on the basis that they were known to have closely aligned radio/optical/ultraviolet structures[3] and are accessible from La Silla. For 3C277.2 we obtained three images at two different position angles through a B (0.44 μm) filter, whereas for 3C368 we have six images all at different position angles through a V (0.55 μm) filter and five images at two position angles through

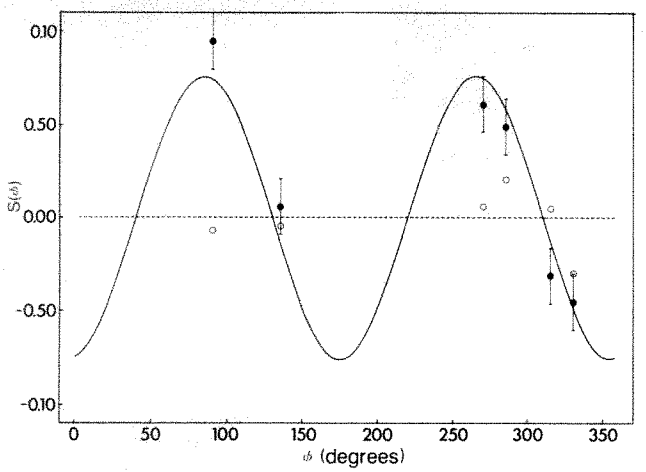

FIG. 1 Measurements (●) of $S(\phi)$, the component of the normalized Stoke parameters for linear polarization, for the V images of 3C368 and the fitted cosine curve from the formula given below. Also shown is the average $S(\phi)$ for faint stars in the same frames (○). For each frame recorded at instrumental position angle ϕ a parameter $S(\phi)$ is derived from the intensities of the two images of the object $i(\phi)$ and $i(\phi+90°)$ and from the average intensities of bright-field stars, which are assumed to be unpolarized, $i^u(\phi)$ and $i^u(\phi+90°)$:

$$S(\phi)=\left(\frac{i(\phi)/i(\phi+90°)}{i^u(\phi)/i^u(\phi+90°)}-1\right)\Big/\left(\frac{i(\phi)/i(\phi+90°)}{i^u(\phi)/i^u(\phi+90°)}+1\right)$$
$$=P\cos 2(\theta-\phi)$$

where P is the degree of linear polarization and θ is the position angle of the plane of vibration of the **E** vector. P and θ can then be derived from two or more observations taken at different position angles[13].

an R (0.70 μm) filter. The results are presented in Table 1. To make a preliminary check on the spatial distribution of polarization across 3C368, which is clearly resolved, we have measured that the polarization of the nucleus alone is not higher than the integrated polarization. The extended parts of the galaxy must therefore be polarized. A similar check is not possible for 3C277.2, because its bright central component, which we could measure, is only slightly extended in the direction of the radio axis.

To gain a reliable understanding of the errors inherent in this type of observation, we have submitted the data to several tests, which are described below. First, we emphasize that each value of $S(\phi)$ is derived from measurements made on a single frame and that effects of instrumental polarization (usually below 1%) are already removed in $S(\phi)$ using bright stars assumed to be unpolarized. For 3C368 in the V band, where we have images at more than two position angles, all the measurements of $S(\phi)$ are consistent with the expected cosine curve (see Fig. 1).

Because the main difficulty in the measurement of the intensity of the various source images is the sky subtraction, the errors on P and θ are derived from the standard deviation in the measurement of the sky over object-free apertures of the same size as those used for the galaxies, propagated through the calculation of $S(\phi)$ and, subsequently, the fitting procedure using Monte-Carlo simulations. To check whether any systematic non-linearity is present in the polarization measurement, which is not removed by the correction for instrumental polarization because this uses stars that are much brighter than the galaxies, we have measured the average $S(\phi)$ for four stars in each V frame of 3C368, the brightnesses of which bracket that of the galaxy. The results are shown in Fig. 1.

We have also examined the possibility that a fraction of the observed polarization might be induced by the interstellar medium in the Galaxy. Using the relationship[14] between the maximum amount of galactic interstellar polarization (P_{ISM}) and the galactic extinction[15] we find that $P_{ISM}\leq 0.05\%$ for 3C277.2 ($b=79°$) and $P_{ISM}\leq 1.2\%$ for 3C368 ($b=15°$). For 3C368 the position angle of the **E** vector of the polarization induced by the interstellar medium of our galaxy would be close to the one measured for the object[16]. We have therefore looked at the polarization of an extended object at 43 arcsec in position angle 338° from 3C368, which has the image profile of a galaxy. The component of the polarization of this object along θ of 3C368 is below 0.5% in the V band. The null polarization measured for 3C277.2B provides a similar argument, although the very low galactic extinction already excludes any contribution of galactic interstellar polarization for 3C277.2.

Finally we estimate that the contribution of emission lines is ~9% of the detected radiation in both filters for 3C368, using the equivalent widths of Djorgovski *et al*[17]. If the lines are unpolarized, then for the continuum alone $P_{corr}=8.3\pm0.9\%$ in V and $P_{corr}=2.7\pm1.2\%$ in R.

The polarization measured for 3C277.2 is larger than that measured in the optical for any extended, lobe-dominated radio source at low redshift[18] and is at the upper end of the range observed in the highly polarized, violently variable quasars[19]. The V-band polarization for 3C368, although somewhat lower, is still larger than that measured for the nuclei of most low-redshift extended radio sources. In this source we also have evidence that the polarization is wavelength dependent, as the R-band measurements give a lower polarization.

The strongest conclusion from our results is that a large proportion of the ultraviolet light in the two galaxies is non-stellar. This property, especially if it proves to be a general one, has important implications for models that seek to explain the ultraviolet excess in terms of star formation, jet induced or otherwise. It is unlikely that the integrated light from the two sources is dominated by highly polarized quasar-like sources in the nuclei because such sources are invariably associated with compact radio structures and small emission-line equivalent widths, whereas both 3C368 and 3C277.2 have extended, lobe-dominated radio sources[17,20] and 3C368 at least has large emission-line equivalent widths[17]. One possibility is that there

TABLE 1 Polarimetry results for high-redshift galaxies

Object	z	Obs. date	Filter	$\Delta\lambda_{rest}$ (Å)	Magn.	P (%)	P_{corr} (%)	θ (deg)	PA_{rad} (deg)
3C277.2	0.766	10 Apr. 1989	B	2150–2850	B=22.0	21±4	21±4	164±6	61
3C277.2B	—	10 Apr. 1989	B	—	B=22.5	6±7	0±7	—	—
3C368	1.132	18 July 1988	V	2250–3000	V=21.4	7.6±0.9	7.6±0.9	85±4	18
3C368	1.132	19 July 1988	R	2650–3750	R=20.5	2.8±1.2	2.5±1.2	92±15	18

Results refer to the integrated light from each source. 3C277.2B is an extended object at 7 arcsec to the north-east from 3C277.2 and was labelled galaxy B by Laing *et al*.[27] P_{corr} is the degree of linear polarization corrected for the bias expected in the definite positive quantity P for low P/σ_P[28]. $\Delta\lambda_{rest}$ is the rest frame wavelength range covered by the observation and PA_{rad} is the position angle of the radio axis[3].

is a contribution to the polarized light from synchrotron radiation emitted by the radio plasma, although this seems improbable given the great differences between the ultraviolet and radio morphologies.

The alternative hypothesis, the scattering of beamed radiation from the galactic nucleus, is consistent with the data. The small misalignments (<25°) between θ and the perpendicular to the radio/optical axis can be explained by a plausible geometry for the light beam and for the scatterers. We do not exclude that some of the light might come from stars especially in the rest-frame V band. An indication that this might be true comes from the recent observation that the elongation and alignment with the radio axis are present also in the K band (2.2 μm) in at least a couple of cases[21,22]. Further observations in this band are necessary to show if there are differences with the morphology in the optical bands and to establish the importance of the stellar component. The beaming and scattering hypothesis requires that the nuclei of these galaxies emit intense collimated beams of ultraviolet/X-ray radiation and is therefore relevant to the 'unified schemes'[23,24] for the active nuclei. As a scattering medium, both electrons in a hot halo[25,26] and circumgalactic dust[6] remain viable alternatives and can, in principle, be distinguished from wavelength dependences. For 3C368, our observation that the polarized flux per unit frequency in the V band is about twice that in the R band favours dust scattering, unless the beamed nuclear radiation is much bluer than observed in blazars. A strong test of the scattering mechanism is the observation of the spatial variation of the direction of the **E** vector which should always remain perpendicular to the direction from the light source for a single scattering process. Such observations will be difficult to make on these faint sources and measurements of the direction of the **E** vector in integrated light, although indicative, do not constitute such a definite criterion. Whichever proves to be the dominant scattering mechanism, polarization measurements covering a wide wavelength range will be important in the diagnosis of the nature and evolution of the interstellar medium and close environments of these active galaxies at early epochs. □

The hot interstellar medium toward SN1987A

Qingde Wang, Thomas Hamilton & David J. Helfand

Columbia Astrophysics Laboratory, Columbia University, New York, New York 10027, USA

AN X-RAY image of the field surrounding the supernova SN1987A, derived from the Einstein Observatory Large Magellanic Cloud (LMC) Survey, has allowed us to constrain the properties of the hot ionized medium along the line of sight to the supernova. If the absorption feature observed in the optical spectrum of the supernova at 6,379.7 Å[1,2] is identified with [Fe X] λ = 6,375 Å, we find that an extraordinarily high iron abundance must be present, either in the hot interstellar medium of the LMC or in coronal gas between that galaxy and the Milky Way.

SN1987A is located on the outskirts of the 30 Doradus region, a large star-formation complex that was observed extensively with the imaging proportional counter (IPC) on board the Einstein Observatory (see ref. 3 for a description of the instrument and the Observatory). In Fig. 1, we present a 0.15–3.5 keV X-ray image of the region surrounding the site of the supernova; the data have been background subtracted, and the instrument response has been deconvolved using a maximum-entropy algorithm (Q.W. and D.J.H., manuscript in preparation).

This field includes several large OB associations[4] (groups of massive main-sequence stars) and diffuse nebular emission in both the optical and radio bands[5,6]. The X-ray surface brightness[7] displays a morphology similar to that of the optical filaments, which are sketched in Fig. 1 for reference. There is no indication that the ISM at the position of the supernova differs significantly from that in the surrounding region. Thus, we would expect that the line of sight to SN1987A samples an ISM with the same general properties as that in the surrounding regions, unless there is a local (<10 pc) variation associated with SN1987A itself.

We have obtained the X-ray surface brightness in the direction of the supernova by summing the flux in a circle of 2-arcmin radius centred at right ascension (1950) = $05^h\ 35^m\ 50^s$, declination (1950) = −69°17′58″: $S_x(0.15\text{–}3.5\ \text{keV}) \leq 2.4 \times 10^{-3}$ photons s^{-1} arcmin^{-2}. Adopting a spectral model[8] for an optically thin thermal plasma at a temperature of 10^6 K, the temperature at which the equilibrium ionization fraction of Fe^{+9} is at a maximum, we derive an X-ray surface emissivity of

$$L \leq 10^{34} \delta \text{ erg s}^{-1} \text{ arcmin}^{-2} \quad (1)$$

where δ is a dimensionless interstellar absorption correction and a distance of 50 kpc for the LMC has been adopted. (The location of the X-ray emitting region with respect to the observed neutral gas along this line of sight is unknown. Comparison of the X-ray surface brightness in this location with positions a few degrees away (off the LMC) suggests that the bulk of the emission is associated with the LMC implying a lower limit for the absorption equal to the galactic H I (neutral, predominantly atomic hydrogen) column density of $\sim 6 \times 10^{20}$ cm^{-2}. An upper limit to the absorption would include the entire H I column density along this line of sight, 3.5×10^{21} cm^{-2}. With this range of possible values $25 \leq \delta \leq 600$.)

The hot ionized medium (HIM) X-ray volume emissivity ε in our observing band can be expressed as $\varepsilon = n_e n_{\text{HIM}} \Lambda_R(T)$ erg s^{-1} cm^{-3} where n_e and n_{HIM} are the electron and ion number densities in the plasma and $\Lambda_R(T)$ is the cooling function $\Lambda_R(T) \simeq 3 \times 10^{-23} \xi$ erg cm^3 s^{-1}, where we assume that the heavy elements all have their cosmic proportions with respect to the Fe abundance ξ in solar units. The function $\Lambda_R(T)$ is nearly constant over the temperature range 10^6–10^7 K. We can obtain a crude measure of the temperature of the X-ray emitting

gas by comparing the ratio of detected counts in the hard (0.8–3.5 keV) and soft (0.15–0.8 keV) bands with model spectra that include the effects of the instrument response and various absorbing column densities. The observed hardness ratio in the 2-arcmin region surrounding the SN is 0.18 ± 0.08—a range of temperatures from $0.5\text{–}1.5 \times 10^7$ K is consistent (at 90% confidence) with this value for an optically thin thermal plasma with solar abundances observed through the allowed range of absorbing column densities. Figure 2 shows the observed emissivity as a function of temperature for these different column densities.

We can now express the X-ray surface emissivity L as

$$7 \times 10^{16} n_e N_{\mathrm{HIM}}\, \xi \ \mathrm{erg\ s^{-1} arcmin^{-2}} \qquad (2)$$

From equations (1) and (2), we obtain

$$n_e N_{\mathrm{HIM}}\, \xi \lesssim 1.4 \times 10^{17}\, \delta\ \mathrm{cm^{-5}} \qquad (3)$$

We wish to compare this result to the putative optical detection of coronal gas in the direction of SN1987A. In particular, two sets of authors[1,2] have reported an absorption feature centred at 6379.70 Å corresponding to a velocity for an [Fe X]-line rest wavelength of 245 km sec^{-1}, which is consistent with that of the LMC. The equivalent width of the line is reported as $\sim 2.5 \times 10^{-3}$ Å, implying a total Fe column density (including all ion stages) of $N_{\mathrm{Fe}} \geq 10^{17}\ \mathrm{cm^{-2}}$. The corresponding HIM column density is

$$N_{\mathrm{HIM}} \geq 3.2 \times 10^{21}\, \xi^{-1}\ \mathrm{cm^{-2}} \qquad (4)$$

This HIM column density exceeds the neutral-hydrogen column density of $N_{\mathrm{HI}} = 2.75 \times 10^{21}\ \mathrm{cm^{-2}}$ (Waite 1988 as quoted in ref. 2). Comparison with the X-ray-derived HIM column density derived from equation 3 leads to the relation

$$n_e^{-1} \delta \geq 2 \times 10^4\ \mathrm{cm^3} \qquad (5)$$

Also, we have

$$N_{\mathrm{HIM}} \sim n_e h \qquad (6)$$

where h is the scale height of the X-ray emitting gas. These relations allow us to constrain the origin of the HIM responsible for the observed X-rays and essentially rule out the possibility that 6379-Å line represents Fe X absorption.

As stated above there is no indication that the ISM along the line of sight to SN1987A differs significantly from that in the surrounding region. Models in which the absorbing iron exists in a region small compared to the resolution of the IPC, models to which the above equations therefore do not apply, can be excluded by other considerations. In particular, we consider the case in which the observed iron was created in SN1987A itself, or in a previous, nearby SN. The optical light curve of the supernova has been used to infer that $0.07 M_\odot$ of iron was created and ejected in the explosion[9], and current theoretical calculations show that the mass of iron ejected in type II events varies little (~15%) with the mass of the progenitor[10]. With this quantity of iron, the column density N_{Fe} required to explain the optical absorption line demands that the dimension of the ejecta be <1 pc. The observed velocity width of the absorption line, however, is $\lesssim 60$ km s^{-1}, whereas γ-ray[11] and infrared[12] spectra of the SN1987A mantle reveal a velocity dispersion in the iron layer of ~3,000 km sec^{-1}. If the iron were from the remnant of some previous supernova along the line of sight, our requirement for a path length of <1 pc would suggest a very young (<500 yr) object for which there is no other evidence and in which velocities would greatly exceed the observed line width. A circumstellar origin for the line is also ruled out[2] by several orders of magnitude. Thus, the possibility of producing the large iron column density in a single, highly localized source is excluded.

Alternatively, the observed coronal gas could be the integrated product of a period of locally enhanced star-formation activity, such as a giant bubble created by the nearby OB associations[4]. The combined action of stellar winds from high-mass stars and multiple supernovae create a hot, low-density cavity with a diameter D given by $D \approx 130 (N_{\mathrm{SN}_{200}} t_6^3 n_0^{-1})^{1/5}$ pc where $N_{\mathrm{SN}_{200}}$ is the number of stars capable of producing supernovae normalized to 200 (ref. 13, 14), t_6 is the age in units of 10^6 yr and n_0 is the original mean density of the ISM. If we include an enrichment resulting from the production of $0.1 M_\odot$ of Fe in each of 200 SN over 5×10^7 yr, the expected column density of iron can be expressed as

$$N_{\mathrm{Fe}} \sim 6 \times 10^{54} N_{\mathrm{SN}_{200}} t_6 D^{-2}$$
$$\sim 5 \times 10^{13} N_{\mathrm{SN}_{200}}^{3/5} n_0^{-2/5} t_6^{-1/5}\ \mathrm{cm^{-2}}$$

which is several orders of magnitude below the observed value

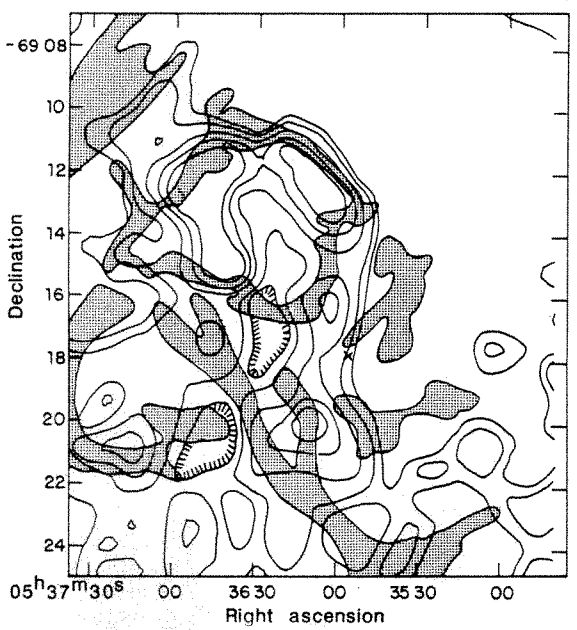

FIG. 1 A background-subtracted iso-intensity X-ray contour map for the SN1987A field with Hα filaments indicated by shading. The X-ray data refer to the Einstein energy band (0.15–3.5 kev) and have been processed with a maximum-entropy algorithm. Contour levels are $(1, 1.2, 1.6, 2, 2.4) \times 10^{-4}$ counts arcmin^{-2} s^{-1}. The cross in the centre marks the location of the supernova.

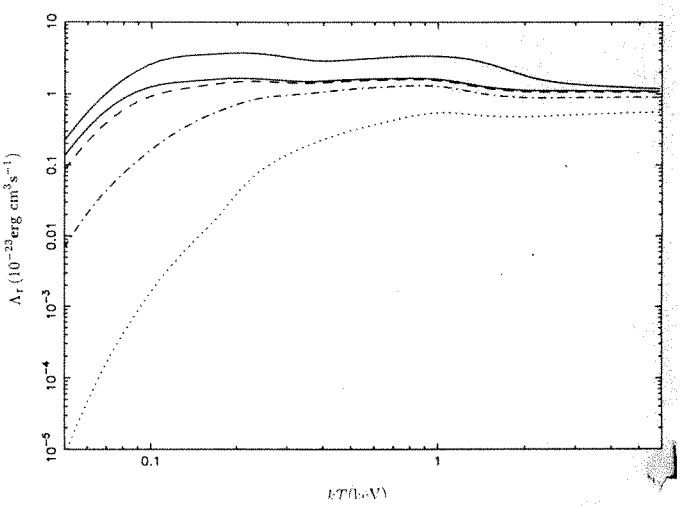

FIG. 2 Integrated X-ray emissivity in the Einstein energy band (0.15–3.5 kev) as a function of the HIM temperature. The top curve gives the function for normal solar abundances, whereas the lower three curves are for one-half solar abundance. To illustrate ISM absorption effects, we have included the observed emission through ISM column densities of 5×10^{19}, 5×10^{20} and 5×10^{21} cm^{-2} as the dashed, dash-dot and dotted curves respectively.

and is a decreasing function of the lifetime of the bubble.

Ultimately, such a bubble can evolve to a dimension comparable to the scale height of the dense ISM in the galactic plane whereupon it will merge into the halo of the LMC. We now examine the possibility that the [Fe XXV] line originates in such a hot LMC halo. The volume occupied by halo gas would greatly exceed the resolution of the IPC and we can use equations (2) through (5) to constrain severely the physical properties of the gas. In this case, the H I absorbing column density in the LMC cannot affect the observed X-ray emission; that is, $\delta \sim 25$ and we have from equation (5) $n_e \leq 10^{-3}$ cm^{-3}. Thus, from equation (6) we require $\xi h \geq 2{,}000$ kpc or forty times the distance to the LMC using cosmic abundances. For an assumed disk mass of $10^{10} M_\odot$ and a disk radius of 3 kpc, the 10^6-K HIM would have a scale height of ~ 1 kpc and ξ is constrained to be $\geq 10^3$.

As it is clear that the general ISM does not have this iron abundance, it is necessary to locate the absorbing material in a hot coronal layer that is $\geq 50\%$ iron. Such a layer would have a scale height of a few hundred parsecs and a cooling time of $\sim 10^5$ yr. The nucleosynthetic yield of type I supernovae is adequate to create such a layer in 10^8 yr, although it is difficult to see how the required temperature ($\sim 10^6$ K) could be maintained consistent with an upper limit to the absorption line width of 60 km s^{-1}.

Finally, we consider the independent constraint on the HIM in the LMC imposed by the radio pulsar 0529−66. The dispersion measure for this object is 125 cm^{-3} pc (ref. 15) and, assuming it is in the LMC, this value sets an upper limit on the electron column density in any coronal gas between the Milky Way and the LMC. Subtracting the galactic contribution of $1.6\text{-}4.0 \times 10^{20}$ cm^{-2} (ref. 15), we find $N_{Fe} \leq 10^{16} \xi$ cm^{-2}. This value, already more than an order of magnitude below the reported Fe XXV column density for solar abundances, is an extreme upper limit in that gas at much lower temperatures ($\sim 10^4$ K) is likely to contribute substantially to the electron column density. Again, we would require an extremely high iron abundance in the coronal gas if this constraint is to be met. □

Short-time large-scale restructuring of the solar photosphere

V. N. Karpinsky

Central Astronomical Observatory of the USSR Academy of Sciences, 196140 Pulkovo, Leningrad, USSR

SOLAR granulation consists of small-scale brightness variations on the Sun's surface, caused by horizontal inhomogeneities in the temperature and density of the photosphere[1]. Individual granules are typically 1,000 km across and have lifetimes of about 5 minutes, but the two-dimensional pattern has generally been considered stationary, apart from small deviations over the solar surface and variations during the solar cycle[2]. Here I show that the nature of the granulation pattern changes on a timescale of 5–10 minutes (ref. 3). The number of granules increases coherently by a factor of 1.2–1.6 over an area of $(4\text{–}6) \times 10^8$ km^2, accompanied by a change in the total granular area of a factor of 1.4 and a change in the mean area by a factor of 2, in antiphase with the number of granules. When the number of granules is increasing, formation of new granules by fragmentation exceeds their disappearance by merging by a factor of 3.6, whereas when the number of granules is decreasing merging occurs twice as fast as fragmentation. The mechanism for these changes is unclear.

I have studied the evolution of solar granulation in the quiet photosphere near the centre of the solar disk (heliocentric angle, $\theta = 21°$) over a 15-min period. Nine direct photographs of the solar photosphere were taken by the Soviet Stratospheric Solar Observatory during its flight of 30 July 1970 (09:10:50–09:25:50 UT)[4]. Observations were carried out automatically at an altitude of 20 km. The telescope aperture was 500 mm, and an excellent spatial resolution of 0.25 arcsec could be achieved.

Photometrically calibrated photographs of superior quality were selected for processing. Isophotal maps were constructed using a digital microphotometer. Brightness is defined in terms of deviations ΔI relative to the mean brightness level of the photosphere.

I have defined a granule to be a single bright region for which ΔI is everywhere greater than an arbitrary threshold value of -4%. The closed isophote nearest to this threshold bounds the area of the granule. For $\Delta I > 6\%$, a single granule can include several maxima (ref. 5). This precise definition of the granule makes it possible to distinguish single granules as structural elements on the isophotal maps and photographs and to estimate granular areas with high accuracy and uniformity.

The whole area A under investigation (6.4×10^8 km^2) was divided into nine equal areas ($l = 1\text{–}9$). The time t_k was measured from the first frame.

Figure 1 shows the temporal dependence of the number of granules $N_l(t_k)$ for the individual areas (bold lines) and for the average area $N_A(t_k)$ (fine line).

$$N_A(t_k) = \tfrac{1}{9} \sum_{l=1}^{9} N_l(t_k)$$

Figure 1 and the photographs in Fig. 2 suggest that for all areas there is a similar systematic variation in the number of granules with time, but this visual impression requires statistical justification. The correlation coefficient of the variations in the number of granules over these nine areas is >0.74, that is, significantly different from zero (confidence level, $1 - \alpha \geq 0.95$) for six areas (the exceptions are $l = 6, 7, 8$). The variation of the granule number for the area B formed by averaging these six areas,

$$N_B(t_k) = \tfrac{1}{5} \sum_{l} N_l(t_k), \quad l = 1\text{–}5, 9$$

is shown in Fig. 3*a*.

I have assumed the variation of the number of granules with time to have the following form, incorporating a stochastic component:

$$N_l(t_k) = n_0 + \kappa_l n(t_k) + \nu_{kl}$$

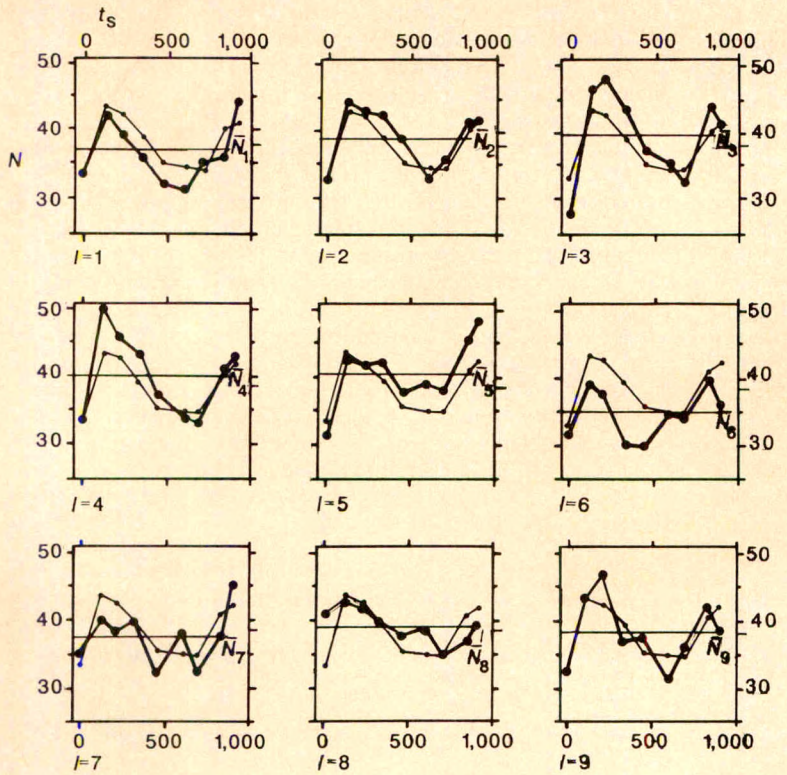

FIG. 1 The variation of the number of granules with time for nine equal sub-areas (8,333 × 8,500 km) of the whole area A (25,000 × 25,500 km) $N_l(t_k)$ (heavy line), and that for the average area $N_A(t_k)$ (thin line). Here $k = 1$–9 is the frame number and t_k is the time of the frame at the start of the series. The mean number of granules for each area l, $\bar{N}_l$, is $\frac{1}{9}\sum_{k=1}^{9} N_l(t_k)$, and for average area A, $\bar{N}_A$, is $\frac{1}{9}\sum_{l=1}^{9} \bar{N}_l$.

Here n_0 is a constant, $\kappa_l n(t_k)$ is the time variation for the area l and κ_l is the amplitude relative to the mean for area B ($\sum_{k=1}^{9} n(t_k) = 0$ and $\frac{1}{6}\Sigma_1\ \kappa_l = 1$). ν_{kl} is a statistical component (noise). I assume that $l = 1$–5, 9 $\sigma\{\nu_{kl}\} = \sigma$ is constant and that the ν_{kl} are uncorrelated for its root mean square different areas and frames as well as being uncorrelated with the systematic variations $n(t_k)$. I estimate the variables

$$\hat{n}_0 = \bar{N}_B = \tfrac{1}{9}\sum_{k=1}^{9} N_B(t_k) = 39.2$$

$$\hat{n}(t_k) = N_B(t_k) - \bar{N}_B \qquad \text{(Fig. 3}a\text{)}$$

$$\hat{\sigma} = \hat{\sigma}\{N_l(t_k) - N_B(t_k)\}, \qquad \hat{\sigma} = 2.5,\ k = 1\text{–}9,\ l = 1\text{–}5, 9$$

The dashed lines in Fig. 3*a* mark the range $N_B \pm 3\hat{\sigma}/\sqrt{6}$. Hence it follows that: (1) The systematic coherent variations of the number of granules in the areas $l = 1$–5, 9 (the total area is equal to 4.3×10^8 km^2) are real. The confidence level of its deviation from random variations is $1 - \alpha \geq 0.99$. The number of granules varies by a factor of 1.2–1.5 in 2–5 min. (2) The noise, $\hat{\sigma} = 2.5$, is significantly less than that expected in the case of the poissonian distribution $\hat{\sigma}_p = \sqrt{\hat{n}_0} = 6.2$. (3) The systematic variations of the number of granules in the areas $l = 6$–8 are less pronounced due to the small amplitude of κ_l and to the 2.5-fold increase in the noise for $l = 8$.

The time variation of the number of granules $N(t_k)$ (Fig. 3*b*), the total granule area $S(t_k)$ (Fig. 3*c*), the mean granule area $s(t_k) = S(t_k)/N(t_k)$ (Fig. 3*d*) and the deviation of peak brightness from the mean (Fig. 3*e*) have been estimated for a family of granules in area C, corresponding to $l = 1$, 2 and occupying an area of 0.7×10^8 km^2. Levels $N = \frac{1}{9}\sum_{k=1}^{9} N(t_k) = 39$ (solid line) and $N \pm 3\hat{\sigma}$ (dashed line) are indicated in Fig. 3*b*.

The qualitative changes that alter a granule as an individual structural element are: the birth of a new granule; its fading away; the fragmentation into two or several granules; and the merging of the two or several granules. During the time intervals between such events a granule remains qualitatively unchanged but its area, brightness and other quantitative characteristics may change. The mean time intervals between the different kinds of events as well as variations of the total and mean granular areas associated with them have been also determined. The sections of the N, S and s curves (Fig. 3*b*, 3*c*, 3*d*) where the values are increasing, decreasing and constant were analysed separately.

The main results for the area C may be summarized as follows: (1) The number of granules in the area C increases by 1.5 times during a time interval of 300 s from its minimum ($t_6 = 600$ s) to its maximum ($t_9 = 900$ s). This is significantly greater than the scatter that is due to noise ($\alpha < 10^{-3}$). At the same time, the

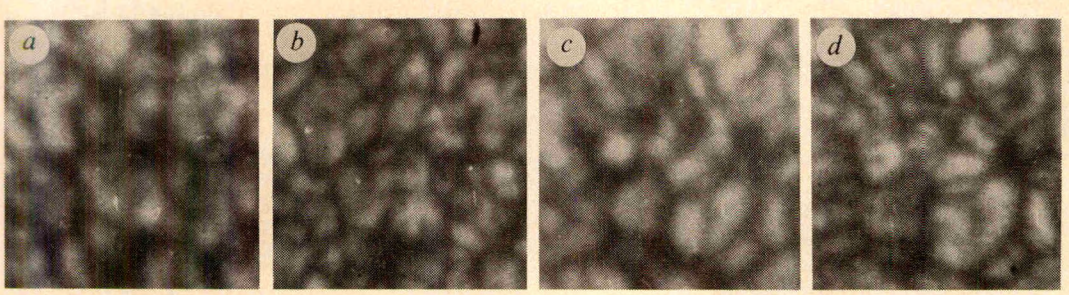

FIG. 2 The variation in granulation structure for area $l = 3$. *a*, $t_k = 0$ s, *b*, $t_k = 210$ s, *c*, $t_k = 690$ s, *d*, $t_k = 840$ s.

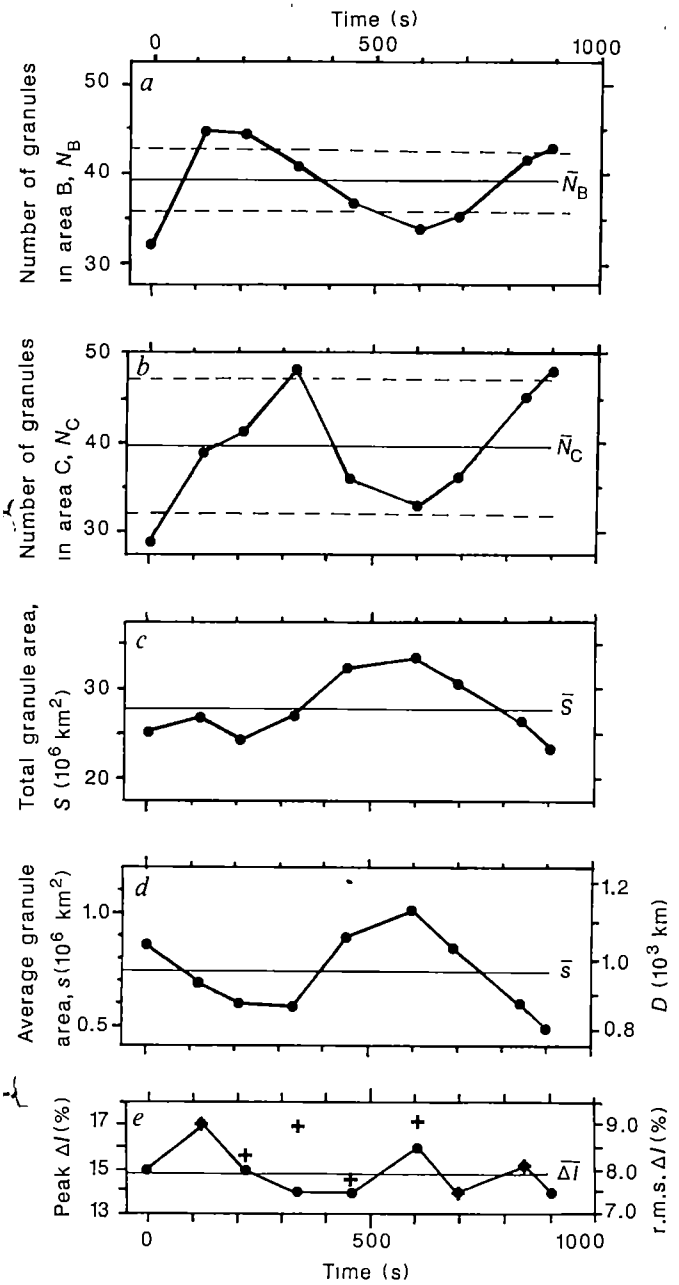

FIG 3 The variation of the solar granulation characteristics *a*, The time dependence of the number of granules for area B, averaged over the six sub-areas $l=1$–5, 9 Also shown are the mean number of granules, $\bar{N}_B = \frac{1}{9}\sum_{k=1}^{9} N_B(t_k)$ (thin line), and the limits of the range, $\bar{N}_B \pm 3\hat{\sigma}/\sqrt{6}$ (dashed lines) which indicates the spread about $\bar{N}_B$ that is due to the statistical noise (dashed lines). *b*, The time dependence of the number of granules for the area C, $N_C(t_k)$ Also shown are the mean number of granules in area C, $\bar{N}_C = \frac{1}{9}\sum_{k=1}^{9} N(t_k)$, and the limits of the range $N \pm 3\hat{\sigma}$, which indicates the spread about N_C that is due to the statistical noise (dashed lines). *c*, The total area occupied by the granules of area C, $S(t_k)$. The mean total area $\bar{S} = \frac{1}{9}\sum_{k=1}^{9} S(t_k)$ is also shown *d*, The time dependence of the mean granule area for area C, $s(t_k) = S(t_k)/N(t_k)$. The time-averaged mean granule area, $\bar{s} = \frac{1}{9}\sum_{k=1}^{9} s(t_k)$, is also shown. *D* is the corresponding diameter for a circular granule *e*, The mean peak-brightness deviation of the granules of the area C, relative to the mean brightness of the photosphere ΔI (line). The root-mean-square brightness contrast for the area A r m s ΔI (crosses) is also shown The mean brightness of the photosphere is assumed as 100%

total granule area decreases similarly and consequently the mean granular area decreases by a factor of two (Fig. 3*b*–*d*). Correlation between the number of granules and their mean area is very high ($r = -0.89$) If the observed changes are periodic the possible period should be ~10 min). (2) The fragmentation and merging of a granule is five times as frequent as its birth or fading away. The mean lifetime of a granule as an individual structure is 5–6 min. (3) The balance of granule fragmentation and merging is not maintained when the number of granules is changing. When the number of granules is increasing, fragmentations are three times as frequent as mergings but when N_C is decreasing, fragmentations are twice as rare as mergings. (4) Granule merging is accompanied mainly by growth of their total area, and fragmentation is accompanied by a decrease. Thus there is a decrease of the total granulation area with an increase in their number and vice versa. When the granules are not changing qualitatively they exhibit a tendency to decrease their area with time, not to increase it as has been supposed[6] (5) Variations in the mean granule area are primarily due to changes in the number of granules rather than to changes in the total area.

These variations cannot be explained by differences in the image qualities of the various photographs. The conventional measure of image sharpness when studying granulation is the root-mean-square (r.m.s.) brightness contrast on the photograph, r.m.s. ΔI. For our images this value is large (r.m.s. $\Delta I = 7.8$–9.1% for a wavelength of 465 nm)[1], it varies little between photographs and it does not correlate with either the number of granules or with their mean area. The same type of behaviour is shown by the peak ΔI which is also rather sensitive to a decrease in the spatial resolution and to measurement errors (Fig. 3*e*). This implies a high quality and uniformity of the photographs employed in the study. Tests were conducted which revealed that the presence of some blurring of the images does not appreciably change the number of granules. Two prints were made from one of the sharpest photographs ($t_k = 210$ s), one of which was deliberately defocused to blur it to a greater degree than was likely to occur for any of the actual photographs. Counting the number of granules by the adopted technique gave similar results for both the sharp and the defocused frames. I therefore conclude that the observed collective behaviour of this substantial ensemble of granules is genuine. The restructuring occurs over an area that is 1,000 times larger than that of a single granule[1,5] and has been followed over a time of 300 s which is similar to the lifetime of a granule. The changes result from the combination of complex nonstationary processes which are, in a number of cases, asymmetric with respect to time inversion. These results imply a connection between the fine structure of the solar atmosphere and the large-scale, possibly global, processes on the Sun. This relationship has not been taken into account in gas-dynamics simulations of granulation[7–9]. The temporal behaviour should be taken into consideration when estimating changes of the granulation characteristics during the solar activity cycles.

My conclusions have been drawn from a single set of data only. How representative they are of the photosphere as a whole and the scale and mechanism underlying the relevant processes remain to be clarified. □

Influence of nitrogen fertilization on methane uptake in temperate forest soils

METHANE, a long-lived gas (8–10 years residence time), is important in the chemistry of the atmosphere and the Earth's radiation balance[1–3]. The tropospheric abundance of CH_4 has been increasing by ~1.1% yr^{-1} over the past decade[4,5]. The cause of this increase may be due to either increases in global sources or decreases in global sinks[1,6,7]. Although considerable research has focused on measuring CH_4 emissions from major biological sources[7,8], much less is known about the magnitude of, and factors controlling, biological sinks of CH_4. The largest biological sinks for methane are microorganisms in aerobic soils[7]. Here we report a study of CH_4 uptake by aerobic temperate-forest soils. We measured CH_4 consumption rates (up to 3.17 mg CH_4–C m^{-2} day^{-1}) that were higher than reported previously. Globally, soils of temperate and boreal forests may consume up to 9.3 Tg CH_4–C yr^{-1}. We also found that the CH_4 uptake rates of these soils were decreased significantly by elevated soil moisture (14%) and nitrogen additions (33%), implying that nitrogen fertilization may reduce this CH_4 sink.

In the spring of 1988, nine (25 m^2) plots were established in each of two forest stands at the Harvard Forest in central Massachusetts: a 62-year-old red pine (*Pinus resinosa* Ait.) plantation and an ~80-year-old mixed black oak/red maple (*Quercus velutina* Lam./*Acer rubrum* L.) stand. Both stands were established on Gloucester-series soils following pasture abandonment in the early 1900s. Forest-floor soils in both stands are acidic, with pH values of 3.2 and 3.3 in the pine and hardwood stands, respectively. In each stand, three plots served as controls, three received a total of 37 kg N ha^{-1} yr^{-1} (low-N plots), and three received a total of 120 kg N ha^{-1} yr^{-1} (high-N plots). Fertilizer, added as NH_4NO_3, was applied in six equal additions from April to September. The total N applied to the low-N plots was four times the amount these forests normally receive in wet deposition[9,10], but was less than or equal to the amount received by forests in polluted areas of western and central Europe[11–13].

Measurements of CH_4 fluxes between soils and the atmosphere were made using 0.065-m^2, two-piece PVC-plastic chambers to cover the soil surface. The lower half (anchor) of the chamber was permanently implanted 1 cm into the forest floor in April 1988. One anchor was established in each plot. Flux measurements were conducted simultaneously at each of the nine plots in both stands, allowing us to examine both spatial and temporal variability among the various treatments. Air and soil (0–2.5 cm and 2.5–5.0 cm) temperatures were measured during each incubation. Soil moisture was analysed gravimetrically and available soil nitrogen was determined[14].

Methane fluxes were measured six times (every four hours) over a 24-hour period by sealing the chamber top to the anchor (total chamber volume ~5.4 l) for a 30-min incubation. Gas samples (20 ml) were withdrawn from the headspace at the onset of incubation and at 10-min intervals thereafter. Chamber tops were removed at the conclusion of each incubation. A Poropak-Q column and a flame-ionization-detection gas chromatograph were used to separate and analyse methane from the headspace gas samples. Fluxes were calculated by a linear fit of concentration data as a function of the incubation time.

Methane uptake rates were measured in both stands for all treatments from May through October 1988 and the mean uptake rates observed over the sampling period were 0.13 mg CH_4–C m^{-2} h^{-1} in the hardwood control plots and 0.11 mg CH_4–C m^{-2} h^{-1} in the pine control plots. The monthly uptake rates shown in Fig. 1 are the means of rates measured from the biweekly samplings.

Observations of CH_4 consumption in temperate and boreal forests are few, but our study suggests that aerobic soils in these systems are more important than considered previously. Our uptake rates are about ten times greater than measurements in another New England temperate-forest ecosystem, where rates of 0.18 mg CH_4–C m^{-2} d^{-1} were reported[15]. Consumption rates comparable to ours have been found in the Great Dismal Swamp forest only during drought conditions, when the soils became aerobic. Some evidence from the literature indicates that dry tropical-forest soils are also CH_4 sinks[15,17,18] with rates of ~0.18–0.37 mg CH_4–C m^{-2} d^{-1}.

The amount of atmospheric CH_4 consumed by soils of tropical, temperate and boreal forests was estimated using rates from this study and ref. 15 for temperate and boreal forests and rates from refs 17 and 18 for tropical forests. The uptake rates were assigned functional periods of 365, 200 and 120 days in tropical, temperate and boreal systems, respectively, corresponding to the approximate number of frost-free days in these systems. Current estimates (1980) of the areas of tropical-, temperate- and boreal-forest ecozones were developed from ref. 19 and used with the above uptake rates to calculate the magnitude of the individual ecozone sinks.

A new finding based on this analysis is that temperate and boreal forests may play a much larger role than tropical forests

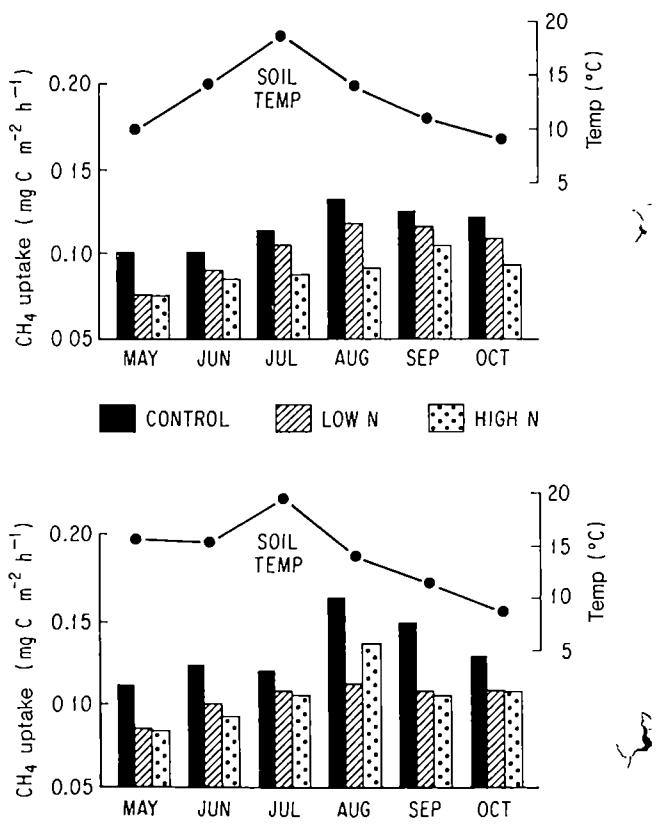

FIG. 1 Mean monthly CH_4 uptake and soil temperature (0–2.5 cm) for pine (top) and hardwood (bottom) stands at Harvard Forest. Low-nitrogen-fertilized plots received 37 kg N ha^{-1} yr^{-1} and high-nitrogen-fertilized plots received 120 kg N ha^{-1} yr^{-1}

in the consumption of atmospheric CH_4 (Table 1). We estimate that temperate and boreal forests annually consume up to 9.3 Tg CH_4-C (Tg = 10^{12} g), an amount 3.7 times larger than the 2.5 Tg CH_4-C consumed by tropical forests. Our estimate for tropical forests is less than the 4 Tg CH_4-C yr^{-1} reported in refs 17 and 18 because we used a smaller ecozone area (18.5×10^{12} m^2) in the calculation. There is considerable uncertainty in estimating the magnitude of the CH_4 sink for these systems, however, because of the limited number of measurements in tropical forests, the lower reported rates for temperate forests[15] and the difficulty in assessing the effects of soil temperature, moisture and nitrogen status on the consumption rates in all the systems.

Methane uptake showed no correlation with the soil temperature over the sampling period May to October (Fig. 1). Linear regression analysis of consumption rates with soil temperature showed no correlations: pine $r^2 = -0.005$; hardwood $r^2 = 0.022$.

We observed that both the moisture conditions and the nitrogen status of the sites affected the magnitude of the sink. The effect of soil moisture conditions on CH_4 uptake is demonstrated by comparing the 11 July rates to the 25 July rates (Fig. 2). Lower uptake rates (paired t-tests $\alpha < 0.001$) were measured in all plots during the 25 July sampling when soil moisture was increased significantly (analysis of variance (ANOVA) $P < 0.01$). This is consistent with other observations[15,16]. The mechanism responsible for effects of moisture on CH_4 uptake has been discussed[15]. Briefly, the organisms that oxidize methane include methanotrophs[20,21] and also nitrifiers[22]. Both methane oxidizers and methane-producing bacteria (methanogens) are thought to be widespread in soils. In fact, they often exist in the same areas. Methanogens are obligate anaerobes, occupying deeper, wetter soil horizons, whereas the methane oxidizers (obligate aerobes) occupy surface, aerobic horizons. Changes in soil moisture result in changes in the net balance of methane production and consumption with wetter conditions shifting the balance towards production and/or reduced gas exchange with the atmosphere.

An important and previously unreported finding of this study is that increased soil nitrogen content resulted in lower CH_4 uptake rates (Fig. 1). After only four months of fertilization, methane consumption in the fertilized plots of both stands was reduced by up to 15% in the hardwood stand and 24% in the pine stand. Analysis of the consumption rates after six months of fertilization indicates that the difference becomes more pronounced—the consumption rates were reduced by ~33% in the high-N plots relative to the controls. We found that, over the six-month sampling period, uptake rates in the fertilized plots of both stands were reduced significantly compared to the control plots (ANOVA $P < 0.005$). The long-term trajectory of this relationship, however, is not well known.

TABLE 1 Estimates of CH_4 uptake by tropical, temperate and boreal forests

Ecozones	Area (10^{12} m^2)	CH_4 uptake range (g C $\times 10^{-4}$ m^{-2} d^{-1})	Tg* C yr^{-1} (min. -max)
Tropical forests			
Tropical moist	10 83	1.87–3 75	0 74–1.48
Tropical seasonal	7 66	1 87–3 75	0.52–1.05
		Total tropical forests	1.26–2 53
Temperate & boreal forests			
Temperate evergreen	4 88	1.87–27.5	0 18–2.68
Temperate deciduous	4 41	1 87–31 7	0.16–2.80
Boreal	11.60	1 87–27.5	0 26–3.83
		Total temperate and boreal forests	0 60–9 31

* Tg = 10^{12} g.

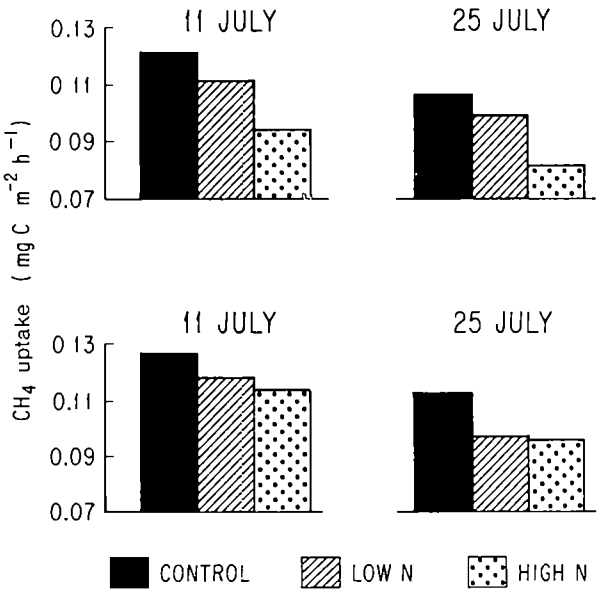

FIG 2 Methane uptake by control and nitrogen-fertilized soils of pine and hardwood forests (top and bottom, respectively) at Harvard Forest, Massachusetts Measurements made before (11 July 1988) and immediately after (25 July 1988) a 6-cm rain event Soil temperatures (0–2 5 cm) ranged from 20 1 to 17 5 °C in the pine stand and 20 6 to 18 2 °C in the hardwood stand on 11 July and 25 July, respectively.

The mechanism responsible for the effect of nitrogen on CH_4 uptake is complex because it involves both methanotrophs and nitrifiers. Laboratory studies indicate that oxidation of CH_4 by a variety of methanotrophs is competitively inhibited by nitrogen, especially ammonium[20,23–25]

Nitrifying bacteria, including the dominant soil ammonium-oxidizing bacterium *Nitrosomonas europaea*, have the ability to oxidize CH_4, even at low atmospheric concentrations[26,27]. Further, laboratory cultures using *N. europaea* showed reduced CH_4 oxidation activity[26] at ammonium concentrations (15 p.p.m.) equivalent to or higher than those present in soils at our sites. The results of these laboratory studies are consistent with our field observations and suggest that CH_4 oxidation may be suppressed in systems that receive high inputs of nitrogen, such as agroecosystems and acid-rain-affected temperate and boreal forests. The identification of a link between nitrogen inputs and CH_4 uptake rates is especially important in understanding the role that aerobic soils play in the global atmospheric methane cycle. The global-scale consequences of a reduction in the CH_4 sink with nitrogen fertilization are uncertain because of the lack of data on the generality of the methane–nitrogen interaction. Further measurements in agroecosystems, pastures and in systems receiving high nitrogen inputs from deposition are necessary to clarify the nitrogen–methane interaction before extrapolation to a global basis. □

Evidence for sulphate-controlled phosphorus release from sediments of aquatic systems

N. F. Caraco, J. J. Cole & G. E. Likens

Institute of Ecosystem Studies, The New York Botanical Garden, Millbrook, New York 12545, USA

SEDIMENTS of aquatic systems play a critical part in controlling phosphorus loading to the water column[1]. Because P loading is an important determinant of productivity in aquatic systems, there has been keen interest in variables that influence P release from sediments. In disagreement with present theories[1,2] our data from 23 different aquatic systems indicate that sulphate concentration of waters is an extremely important variable controlling P release from sediments. The increased P release from sediments at higher sulphate concentrations may help to explain why primary production in freshwater systems (with relatively low sulphate concentrations) tends to be P limited[3], whereas in many saline systems (with high sulphate concentrations) production is often P sufficient[4]. Further, our results indicate that anthropogenically induced changes from atmospheric S inputs could, over time, alter the P cycle of aquatic systems.

To examine the controls of P release from sediments, without the possible artefacts of sediment core studies, we used an *in situ* geochemical approach[5–8] (Fig 1, legend). Briefly, sediment P immobilization is inferred when measured P release is less than that expected from decomposition reactions. Particles reaching bottom sediments show P:C ratios that vary between 3 and 10 mmol per mol C (refs 9 and 10); when the ratio of dissolved P to dissolved inorganic carbon (DIC) release is equal to this value, the decomposition reactions alone may be adequate to explain P release from sediments. Release ratios below 3 mmol P per mol C indicate that sediment uptake is significant, whereas ratios above this value indicate that there is P release from sediments that was taken up previously by sorption, mineral formation or bacterial uptake[7,8]. The advantage of this approach is that it allows us to distinguish between two very different cases: (1) low sediment P release that is due to low availability of degradable organic materials (hence low metabolism); and (2) low sediment P release that is due to the fact that sediments have the capacity to take up P and prevent its release to overlying waters. That is, low absolute P release is not necessarily due to the capacity of sediments to immobilize P (case 1). The ratio of P release to inorganic carbon release (relative P release; RPR) is a far better indicator of the capacity of sediments to immobilize P.

Previous reports suggest that oxygen, through its control on the iron cycle, is the critical variable controlling P immobilization by sediments of aquatic systems[1,2]. The oxygen-control model states that under oxic conditions a micro-layer rich in iron oxide traps P, preventing its release into overlying water, whereas under anoxic conditions these iron oxides are reduced chemically and previously bound P is released into solution[2]. If this model represents the dominant processes occurring in sediments, RPR would be consistently low (<3–10 mmol P per mol C) under oxic conditions and high (>3–10 mmol P mol C) under anoxic conditions[7,8]. Our results do not show any such consistent pattern. In the 23 systems examined, we found a large variation in RPR under both oxic (0.1–10 mmol P per mol C) and anoxic conditions (0.1–35 mmol P per mol C). The difference in RPR between oxic and anoxic conditions is, therefore, small in comparison with the large variation in RPR among systems.

Clearly, some variable(s) other than oxygen must have a major influence on RPR. Our preliminary data and previous reports indicate that such variable(s) are related strongly to the ionic strength of waters[5–8,11]. We therefore tested several variables thought to influence sediment P release that could be correlated with ionic strength (Table 1)[12–18]. Of these variables, sulphate concentration of surface waters was the only variable with predictive significance ($P < 0.01$) under both oxic and anoxic conditions (Table 1).

Our data show that RPR and sulphate concentration of waters are related and that a relationship exists independent of whether bottom waters are oxic or anoxic (Fig. 1). Under oxic conditions RPR increased monotonically from 0.1 to 10 mmol P per mol C over the entire range of sulphate values tested (10–30,000 μM). Anoxic RPR showed a similar pattern to oxic RPR but had a steeper initial slope and reached maximum values at sulphate concentrations of only 100–200 μM (Fig. 1). Considering the entire data set for both oxic and anoxic conditions, three patterns emerge: Group I, brackish and saline systems, with high sulphate concentrations (~3,000–30,000 μM), have high RPR values (3–10 mmol P per mol C) under both oxic and anoxic conditions. In these systems, even under oxic conditions, immobilization of sediment P is generally not large; Group II, fresh water systems with low sulphate concentrations (below about 60 μM) generally have low RPR values (less than 1 mmol P per mol C) under both oxic and anoxic conditions. In these systems, P immobilization in sediment evidently continues to be important even after bottom waters become anoxic; Group III, fresh water systems of intermediate sulphate concentration (~100–300 μM) generally have fairly low RPR under oxic conditions but tend to have very high RPR when bottom waters become anoxic. These are the only systems that correspond to the classic pattern[2] of P immobilization under oxic conditions and P release under anoxic conditions.

TABLE 1 Spearman rank-correlation coefficients between relative P release (RPR) and several variables that might be responsible for controlling P release

	Conductivity	SO_4^{2-}	pH	P C	Sediment Fe	Chlorophyll
Oxic	0 75*	0 85*	0.57*	0 39	0 12	0 19
Anoxic	0 44	0.69*	0 41	0 34	0 20	0.38

'Oxic' refers to RPR when water above the sediments is oxygenated, 'Anoxic' refers to RPR when overlying waters are anoxic.

* Significance at the 99% level P C is the phosphorus-to-carbon ratio of suspended particles (seston) in surface waters This ratio may be a reasonably good indicator of P·C ratios for freshly sedimented particles[9]. Sediment Fe is the iron content of upper 5–10 cm of the sediments. Chlorophyll represents mean surface-water value of chlorophyll *a* during the summer season Twenty-three aquatic systems are included in this analysis, for data sources see Fig 1 The range of values represented from these systems are conductivity, 18–40,000 μS cm^{-1}, sulphate, 11–27,000 μM; pH, 5.5–8 5 (H^+, 0.0032–3.2 μM); sediment Fe, 0.9–4.5% dry weight; chlorophyll 1.5–60 μg l^{-1}

The observed relationship between sulphate and RPR suggests that sulphate may have a role in the control of P uptake by sediments. Although as yet we do not know the mechanism(s), the causality of such a relationship is supported by some experimental evidence indicating that sulphate additions can inhibit P binding by sediments[13,18]. Also, there are several plausible mechanisms whereby sulphate concentrations could influence the ability of sediments to take up P: mechanism (1), sulphate could compete with phosphate for anion sorption sites. This effect may be important in inhibiting P sorption by sediments in brackish and saline systems with extremely high sulphate concentrations (Group I systems; 3,000–30,000 μM)[12]. Sorption competition, however, is unlikely to explain the differences in RPR observed among fresh water lakes (Group II and III systems; 10–300 μM sulphate; Fig. 1) The difference in RPR

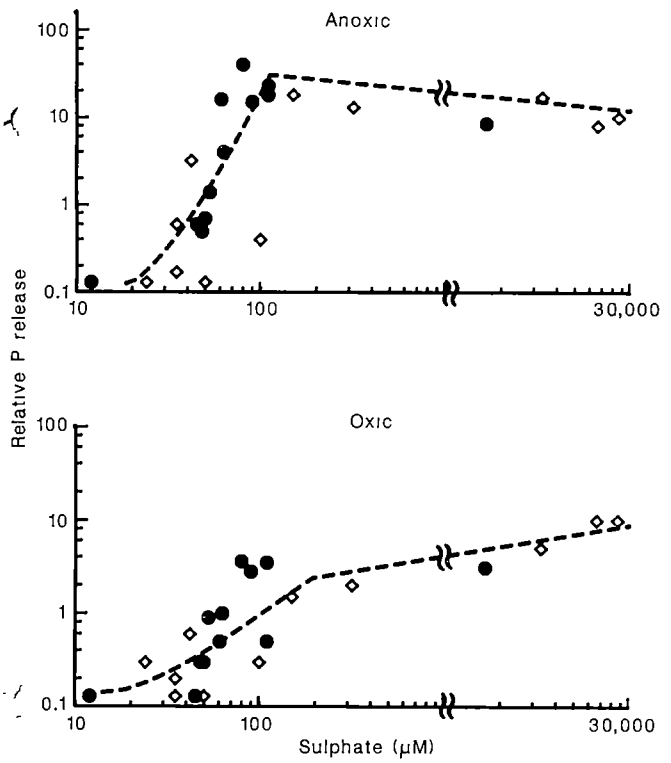

FIG 1 Relative P release (RPR) plotted against sulphate concentration of surface waters for 23 different aquatic systems Release under both oxic (bottom) and anoxic (top) conditions are shown. Data for 12 of the 23 systems shown are from our data (closed circles) Data for the remaining 11 systems (open diamonds) are from D W Schindler (personal communication), K Porter (personal communication) and from refs 5–8 and 23–27 METHODS During summer stratification, water was collected from below the thermocline of lakes on 2–6 occasions using a peristaltic pump Water for analysis of total dissolved P was filtered in line through a Whatman GFF filter and later analysed[28] Samples for dissolved inorganic carbon (DIC) and CH_4 were collected into airtight (BOD) bottles and measured by gas chromatography[29] Oxygen was measured using a YSI oxygen meter Sampling in lakes occurred under both oxic (early season) and anoxic (late season) conditions Oxic RPR is the P DIC accumulation ratio from apparent oxygen utilization of zero to oxygen concentrations of 5% saturation (~300–400 μM of DIC accumulation) Anoxic RPR is the same ratio from 5% oxygen saturation to a DIC accumulation of up to 800 μM (but >400 μM) due to anaerobic decomposition processes Methane was not included in the calculation of RPR This exclusion can lead to underestimations of decomposition under anoxic conditions and, thus, overestimations in RPR. For the 11 systems for which we had methane data, however, this error was small in comparison with the range in RPR. Because methanogenesis is of greater importance in low sulphate systems[30], however, this error would only enhance the observed pattern of increases in RPR at higher sulphate concentrations.

under anoxic conditions is particularly pronounced in these systems and two more mechanisms, both depending on sulphate reduction, may be operative; mechanism (2), sulphides (from sulphate reduction) could bind iron in anoxic sediments[13,19]. Formation of iron sulphides would both prevent the re-supply of iron oxides to surface sediments[19], and the formation of ferrous phosphate compounds within anoxic sediments[13]. This mechanism implies that RPR should be related directly to sulphate reduction and sediment iron content; mechanism (3) sulphate reduction in anoxic sediments or bottom waters can generate alkalinity and elevate pH; high pH values would inhibit P sorption onto iron oxides in sediments[12]. This mechanism implies that RPR should be related to hypolimnetic pH (an indirect effect of many factors including sulphate reduction) and sediment iron content.

In a recent study using enclosures, mechanism (3) was shown to be important for a soft-water lake in Ontario[18]. This same study indicated that mechanism (2) was not important. Our results from a wide range of lakes indicate, however, that this result may not be applicable generally across systems. Using multiple regression analysis we were able to explain 84% of the variation in RPR under anoxic conditions using sulphate depletion in bottom waters and sediment iron content as the independent variables (Table 2). For the same data set, we were able to explain only 20% of the variation in RPR under anoxic conditions using hypolimnetic pH and sediment iron content as independent variables. These results, taken together, suggest that sulphate reduction may be acting to influence RPR and that the dominant mechanism is not related to pH in bottom waters[18]. More work on sediment and pore water chemistry is needed to elucidate fully the mechanisms (and several may be operative) whereby sulphate may be affecting P cycling in aquatic systems.

Whatever the mechanism, the correlation between sulphate and P release from sediments may help to explain a well-known difference between fresh- and saltwater systems. In freshwater lakes P is, in general, the major nutrient limiting phytoplankton growth[3]; in coastal marine systems, on the other hand, phytoplankton production is usually P sufficient and N is limiting to phytoplankton growth[4,20]. This difference is attributed generally to changes in N cycling between fresh and salt waters[20,21]. Our data indicate that P is probably most available in systems with

TABLE 2 Multiple regression models of relative P release (RPR) into anoxic hypolimnia of twelve fresh water lakes

Independent variables	Number of variables	r^2 (adjusted)	p value
Sulphate depletion, sediment Fe	2	0 81	0 002
Sulphate, sediment Fe	2	0 67	0 003
Hypolimnetic pH, sediment Fe	2	0 02	0 36
Table 1 variables including sulphate	6	0 77	0 023
Table 1 variables excluding sulphate	5	0 00	0 74

In all regressions RPR was log transformed to stabilize the variance We were able to obtain significant relationships only if either sulphate or sulphate depletion were included in the suite of independent variables Combinations excluding sulphate but including hypolimnetic pH or surface-water pH did not result in significant relationships RPR (mmol P per mol C) was best predicted from sulphate depletion in bottom waters (μM) and sediment Fe (% dry weight) according to the equation ln (RPR) = 0 11 (sulphate depletion) − 0 97 (sediment iron) − 0 006 Of the variation in RPR explained by this equation, 75% was due to sulphate depletion and 25% was due to sediment iron Data were included for all fresh water systems for which, in addition to the variables listed in Table 1, we had sulphate depletion and hypolimnetic pH Data are from this study (9 lakes), from D W Schindler (personal communication), from ref 23 (2 lakes) and from refs 24 and 25 (1 lake) Sulphate depletion is the maximum observed sulphate depletion above sediments that occurs during summer stratification Similarly, hypolimnetic pH is the pH value above the sediment water interface at the end of summer stratification All other variables are explained in Table 1

very high sulphate concentrations (Fig. 1). Thus, differences in P cycling between freshwaters and salt waters may also influence the switch in nutrient limitation.

A further implication of our findings is a possible effect of anthropogenic S pollution on P cycling in lakes. Our data indicate that aquatic systems with low sulphate concentrations have low RPR under either oxic or anoxic conditions; systems with only slightly elevated sulphate concentrations have significantly elevated RPR, particularly under anoxic conditions (Fig. 1). Work on the relationship between sulphate loading and P release has yet to prove the mechanism behind this relationship. If sediment P release were controlled largely by sulphur, our view of the lakes that are being affected by atmospheric S pollution could be altered. It is believed generally that lakes with well-buffered watersheds are insensitive to the effects of atmospheric S pollution. However, because changing atmospheric S inputs can alter the sulfate concentration in surface waters[22] independent of acid neutralization in the watershed, the P cycle of even so-called 'insensitive' lakes may be affected. □

ROOTH[1] proposed that the Younger Dryas cold episode, which chilled the North Atlantic region from 11,000 to 10,000 yr BP, was initiated by a diversion of meltwater from the Mississippi drainage to the St Lawrence drainage system. The link between these events is postulated to be a turnoff, during the Younger Dryas cold episode, of the North Atlantic's conveyor-belt circulation system which currently supplies an enormous amount of heat to the atmosphere over the North Atlantic region[2]. This turnoff is attributed to a reduction in surface-water salinity, and hence also in density, of the waters in the region where North Atlantic Deep Water (NADW) now forms. Here we present oxygen isotope and accelerator radiocarbon measurements on planktonic foraminifera from Orca Basin core EN32-PC4 which reveal a significant reduction in meltwater flow through the Mississippi River to the Gulf of Mexico from about 11,200 to 10,000 radiocarbon years ago. This finding is consistent with the record for Lake Agassiz which indicates that the meltwater from the southwestern margin of the Laurentide Ice Sheet was diverted to the northern Atlantic Ocean through the St Lawrence valley during the interval from ~11,000 to 10,000 years before present (yr BP).

Evidence for these diversions of meltwater comes from changes in the level of proglacial Lake Agassiz, which acted as a 'clearinghouse' for runoff from a 2×10^6 km^2 area along the southwestern side of the Laurentide Ice Sheet[3]. Before 11,000 yr BP, the meltwater reaching Lake Agassiz overflowed to the Gulf of Mexico through the Mississippi River drainage system (Fig. 1*a*). By ~11,000 yr BP the Laurentide Ice Sheet had retreated far enough to open a series of channels leading to the Lake Superior basin, creating a diversion of the Agassiz

9,930 ± 280 (W-388)	9,700 ± 140 (GAC-797)
9,900 ± 400 (W-993)	

These dates (yr BP) were used to establish the chronology for the routing of meltwater from Lake Agassiz drainage basin during the Younger Dryas cold episode The sample numbers are given in brackets.
* Low-water phase during which meltwater flowed east to the northern Atlantic Ocean.
† Glacial advance that dammed eastern overflow from Lake Agassiz
‡ High-water phase during which meltwater flowed south to Gulf of Mexico

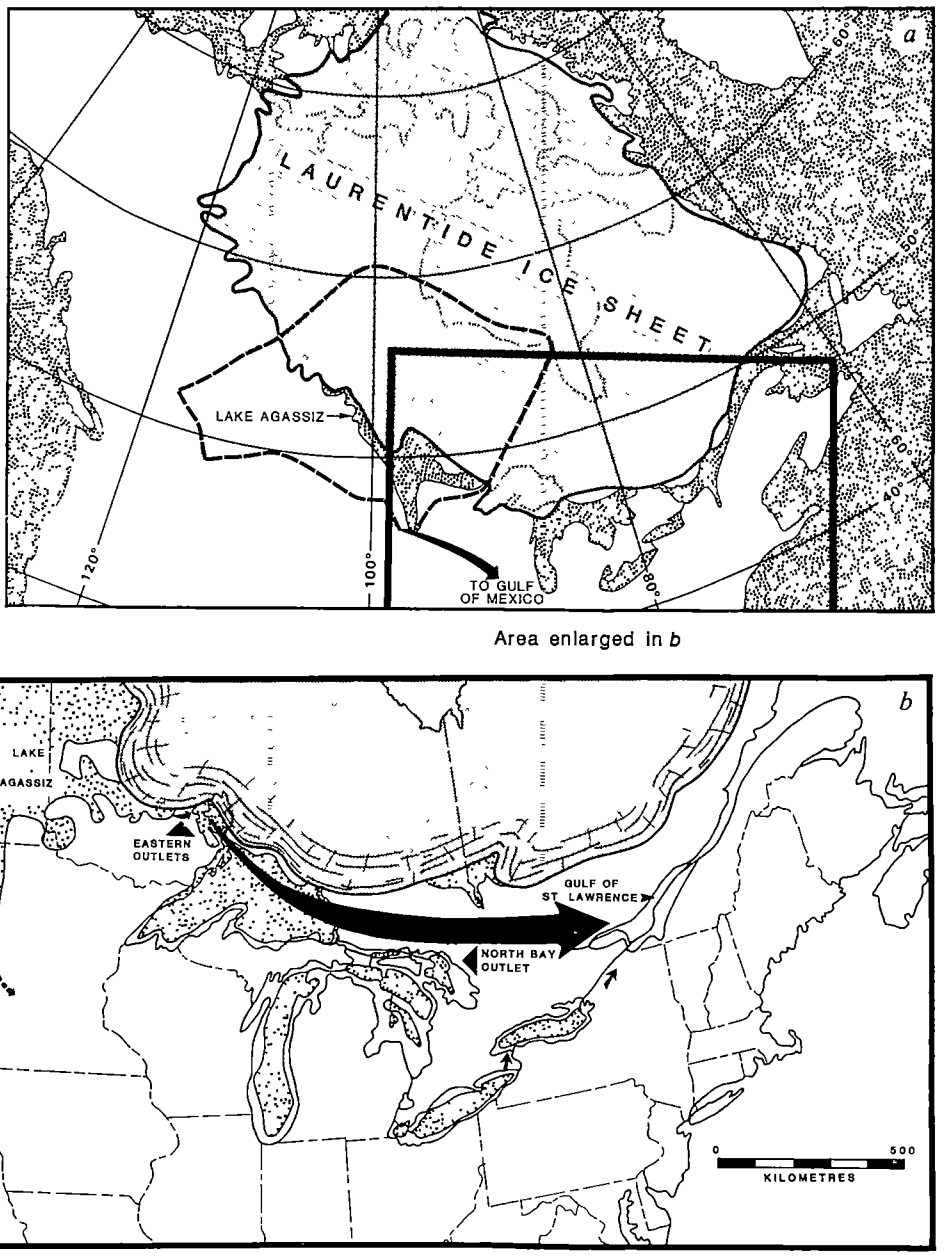

FIG 1 *a*, Map showing Laurentide Ice Sheet and routing of overflow from the Lake Agassiz basin (dashed outline) to the Gulf of Mexico just before the Younger Dryas[22,23]. *b*, Routing of overflow from Lake Agassiz through the Great Lakes to the St Lawrence and northern Atlantic during the Younger Dryas[24]

water eastward through the Great Lakes and the St Lawrence valley to the northern Atlantic (Fig. 1*b*). Thus, during the Younger Dryas, meltwater and precipitation from the Lake Agassiz basin, the discharge of which is estimated[4] to have been ~30,000 $m^3 s^{-1}$, was diverted to the northern Atlantic Ocean from its previous route to the Gulf of Mexico. This diversion caused the level of Lake Agassiz to drop by ≥40 m, creating the Moorhead low-water phase[5]. Radiocarbon dates of material from the portions of the floor of Lake Agassiz exposed during the Moorhead low-water phase range from 10,960 to 10,050 radiocarbon years (Table 1).

Drainage from Lake Agassiz was routed back to the Mississippi River and Gulf of Mexico beginning ~10,000 years ago, when ice of the Marquette glacial advance once again dammed the eastern overflow channels that had linked Lake Agassiz with the St Lawrence during the time corresponding to the Younger Dryas. Lake Agassiz again rose at this time to its Mississippi outlet initiating the Emerson high-water phase. Radiocarbon dates related to both the ice advance in the Superior basin and the Emerson high-water phase are shown in Table 1. Eleven radiocarbon ages for the ice re-advance range from 10,250 to 9,545 yr and average 10,020 yr. Eleven radiocarbon ages for the Emerson high-water phase of Lake Agassiz range from 10,000 to 9,700 yr.

An appropriate independent test for these reconstructions of drainage history is to date meltwater influx episodes to the Gulf of Mexico, recorded in the sedimentary record as negative values in the $\delta^{18}O$ of planktonic foraminifera[12,13]. Because of bioturbation effects however, necessary resolution is not attainable for sediments that accumulate at rates of 8 cm per 10^3 yr. The Orca Basin, located on the continental rise off Louisiana, not only offers high sedimentation rates (50 cm per 10^3 yr) but also anoxic conditions and hence a lack of sediment mixing[14–17]. There is[14,15] a major negative $\delta^{18}O$ spike in Orca Basin core EN32-PC6. Accelerator radiocarbon dating of this core conducted on planktonic foraminifera[18] revealed what seemed to be a sedimentation hiatus covering the time interval of the Younger Dryas. A more recent radiocarbon age of 10,910 ± 160 yr (or 10,500 yr after correction for the ~400-yr age for surface water $\sum CO_2$) for a new sample of mixed planktonic foraminifera from 436–437 cm depth in EN32-PC6, however, supports the contention that accumulation was continuous[17].

Because of our original suspicion that a hiatus existed in EN32-PC6 we turned to a companion core, EN32-PC4, and determined the oxygen isotopic composition of both the white and pink variety of *Globigerinoides ruber* (Fig. 2). The isotope record was radiocarbon dated using the accelerator ^{14}C method (Table 2 and Fig. 2). Both ^{18}O records show the meltwater anomaly[12–15]. The white *G. ruber* record shows a sharp increase (~3‰) in $\delta^{18}O$ at ~11,000 yr BP which is consistent with the cessation of meltwater flow expected from a diversion of the Lake Agassiz water. This increase is followed by a sharp decrease (~2‰) in $\delta^{18}O$ at ~10,000 yr BP which is consistent with the rejuvenation of meltwater flow when the Lake Agassiz discharge was returned to the Mississippi River system.

Had we stopped with the analysis of the white variety of *G. ruber* we would have concluded that the evidence from the Gulf of Mexico is in full agreement with the expectation based on the Lake Agassiz record. The analyses of pink forms of *G ruber*, however, complicates the situation. Although they show the major $\delta^{18}O$ increase corresponding to the eastward diversion 11,000 yr BP, they show no decrease at 10,000 yr BP. Rather, the $\delta^{18}O$ value remains nearly constant from 11,000 yr BP to present. Another puzzling contrast between these two records is that the $\delta^{18}O$ value for the white form of *G. ruber* is 1‰ higher than that for the pink form during glacial and Younger Dryas times, whereas the two forms yield similar values before and after Younger Dryas time. These differences are not easily explained. Net-tow[19] plankton sampling and isotope[20] studies suggest that the pink form of *G. ruber* lives only during summer months, whereas the white form lives throughout the year. As the largest meltwater flux to the Gulf of Mexico would certainly have been during the summer months, this would be the least probable time for the Orca Basin to have been free of meltwater effects.

The important question here is whether the difference between the records invalidates our claim for verification of the cessation event For example, a strong winter cooling (~6 °C) during the Younger Dryas would explain the trough in the $\delta^{18}O$ record in white forms of *G. ruber*. In this case no increase in meltwater flow down the Mississippi 10,000 yr BP would be required. Indeed, faunal data have been interpreted as indicating a cooling of the Gulf of Mexico during the Younger Dryas cold episode[17]. However, no support for a large cooling has been found in the pollen record for the southeastern United States (see ref. 21 for a summary).

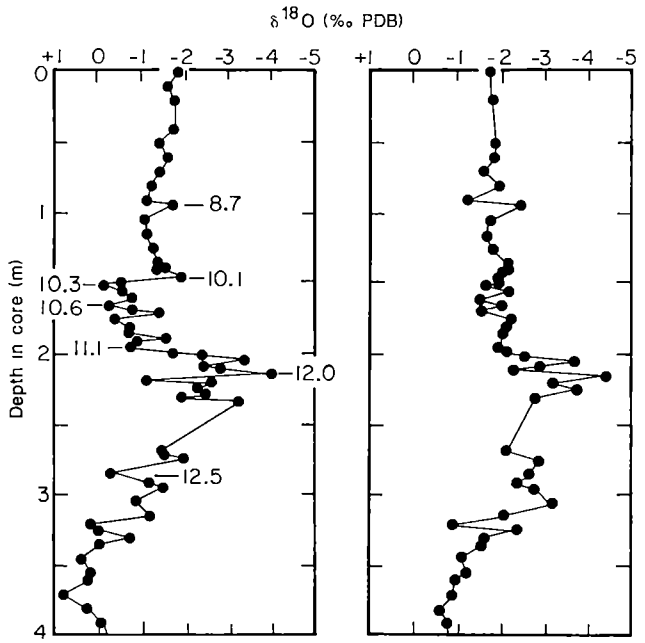

FIG 2 Oxygen isotope changes in two varieties of *Globigerinoides ruber* (white and pink, left and right, respectively) from EN32-PC4 during latest Quaternary are plotted against depth. Ages shown are accelerator radiocarbon ages Both varieties show a major 'meltwater spike' from ~320–200 cm *G ruber* (white variety) shows increased $\delta^{18}O$ 1‰ relative to PDB standard values at the beginning of the Younger Dryas cold episode, consistently high values during the episode (~11,000–10,000 yr BP), and a sudden decrease at 10,000 yr BP termed the 'cessation event'

TABLE 2 Radiocarbon dates of mixed planktonic shells

Sample No	Depth (cm)	^{14}C age (yr)	Corrected ^{14}C age* (yr)
F120	94–96	9,100±190	8,700
F81	144–146	10,490± 90	10,100
F82	150–152	10,700±130	10,300
F83	164–166	11,030± 90	10,600
F84	192–196	11,510±100	11,100
F85	214–216	12,450± 90	12,000
F121	288–290	12,900±150	12,500

These are the ages, determined by accelerator mass spectrometry at ETH Zurich, of mixed planktonic shells from Orca Basin core EN32-PC4 (26° 56 1′ N, 91° 21 7′ W, 2,260 m)

* Corrected for air–sea $\Delta^{14}C$ difference

Although it is unclear how much of the change in the $\delta^{18}O$ observed in the white form of *G. ruber* is due to reintroduction of meltwater and how much to a temperature increase, the chronology of the oxygen isotope record in the Gulf of Mexico seems to be in harmony with that for the record of Lake Agassiz. Although further tests of this hypothesis are required, the fact that the Younger Dryas interval is bracketed by dramatic oxygen isotope changes in the Gulf of Mexico is strong support for the proposal that a major influx in meltwater to the northern Atlantic ocean was responsible for the Younger Dryas cold episode.

Independent oxygen-isotope evidence from the Bay of Biscay (France) for benthic foraminifera[25] and a new coral-based chronology for the sea level during the time interval 15,000–9,000 yr BP[26] suggest that the Younger Dryas interval was one of reduced meltwater flow relative to the warm intervals before and after this event. The problem is that as meltwater from other sectors of the Laurentide Ice Sheet and from the Scandinavian Ice Sheet entered the Northern Atlantic at all times, it might be claimed that the increase in fresh-water input to the northern Atlantic at the onset of the Younger Dryas cold episode caused by the diversion of meltwater from the Mississippi to the St Lawrence was largely offset by a reduction in meltwater input from these other sectors. A further issue regarding the Rooth hypothesis is that the re-diversion of meltwater from the Mississippi to the St Lawrence after 10,000 yr BP failed to produce a cold event comparable to the Younger Dryas. Although we do not have satisfactory answers to these questions, we feel that the cadmium- and carbon-isotope data for benthic foraminifera[27] clearly show that the Atlantic conveyor-belt system did shut down during the Younger Dryas time. Taken together with meltwater-routine chronology we feel that the case for a diversion trigger remains strong. □

THE non-invasive measurement of vascular dynamics and elasticity is critical in understanding haemodynamic conditions of cardiovascular diseases such as hypertension and atherosclerosis[1]. Although there are numerous invasive and *in vitro* techniques[2] for such measurements, until now non-invasive methods have been limited[3]. We have now obtained stroboscopic NMR images[4,5] of the carotid arteries of 80-g rats. The change in the cross-sectional area of arteries of diameter ~600–800 μm was correlated with the change in absolute blood pressure. These are the first microimages[6–9] of a dynamic system and enable the direct visualization of compliance, the non-invasive measurement of Young's modulus, the direct determination of the local effects of vasoconstrictors and vasodilators and the mapping of the entire cardiac cycle.

Figure 1 (left panel) shows a large-field-of-view (FOV) spin-echo NMR image of the left side of the neck of an 80-g rat, whereas the images shown in the middle and right panels correspond to systole and diastole, respectively. The carotid artery at systole appears dark (corresponding to the absence of signal) because the blood that was excited during slice selection had flowed out of the slice by the time the echo was obtained. Fresh unexcited blood had taken its place, thereby affording great contrast. The image at diastole is an extreme example of a complete loss of contrast that occurs when the blood flow is so slow that it is difficult to distinguish between the blood in the artery and the water in the surrounding tissue. This effect was observed only rarely (more representative images at diastole are shown in Fig. 3), and the echo time (T_E) could be adjusted to change the intensity of the blood signal in the artery.

Data such as these shown in Fig. 1 were analysed by drawing expanded plots, the contours of which correspond to the grey levels in the image. Representative plots are shown in Fig. 2. Each of the areas of these plots was measured independently by three individuals, using a planimer. The averages of the three normalized measurements for two rats are shown in Fig. 3. The error bars correspond to the standard error of the three separate measurements. The error is small near systole (~2%) and larger near diastole (~8%) because of the flow effects mentioned above.

The cross-sectional areas of the carotid artery at the extremes of systole and diastole can be correlated with the absolute blood pressure to determine the distensibility, related to the compliance, of the carotid artery. Compliance is defined as the volume change per unit of pressure; our measurements, however, recorded a change in the cross-sectional area. We have assumed that the length of the carotid artery did not change appreciably during the heart cycle, an assumption that is valid in view of separate measurements of the transverse and longitudinal Young's modulus (see below). The distensibility is calculated by:

$$\frac{(A_{\text{systole}} - A_{\text{diastole}})/A_{\text{diastole}}}{P_{\text{systole}} - P_{\text{diastole}}} \times 100\%$$

where P_{systole} and P_{diastole} are the absolute blood pressures at systole and diastole, respectively, and A_{systole} and A_{diastole} are

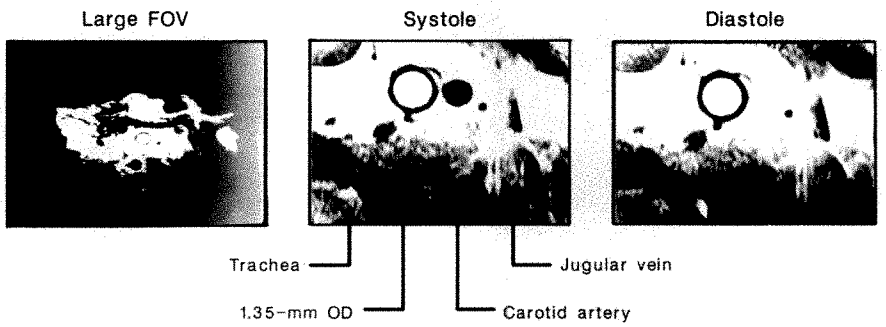

FIG. 1 Spin-echo NMR images of the left side of the neck of an 80-g rat. Left, Field of view (FOV) 33.9 × 33.9 mm; middle, FOV 8.5 × 8.5 mm; this image corresponds to systole. Right, FOV 8.5 × 8.5 mm; image corresponds to diastole.

METHODS. Female Sprague–Dawley rats (80 g) were anaesthetized with ethyl carbamate (urethane, Sigma) in 0.85% saline (w/v) by injecting 850 mg of the solution per kg (body weight) intraperitoneally, and then injecting 850 mg per kg subcutaneously behind the neck. The rats were intubated and a water-filled capillary (10 mm × 1.35 mm o.d.) was inserted near the carotid artery as a marker for vertical positioning. The incision was sutured and electrocardiograph leads were placed on the upper abdomen, away from the surface coil, with the resultant electrocardiogram producing a V_3-like trace. The rat was placed head-down in a specially designed plastic rodent holder that was affixed to the probe. The temperature of the rats decreased to 31 °C and stabilized at that level. They breathed 60% O_2 and 40% N_2. The NMR images were obtained using a Bruker AM 360 equipped with an NMR microscope accessory. The probe circuit was modified to accommodate a 1.4-cm-diameter single-turn surface coil. A 2-ms lobeless sinc pulse was used for the slice-selective 90°-and 180° pulses. The water line-width was shimmed on the desired slice to ~100 Hz. The gradient strengths for the 33.9 × 33.9 × 0.8-mm FOV were 0.69, 0.74 and 1.8 gauss cm^{-1} for the read-out (x), phase encode (y) and slice select (z) directions, respectively. For the 8.5 × 8.5 × 0.8-mm FOV the gradient strengths were 2.77, 1.48 and 1.8 gauss cm^{-1}, respectively. The images consisted of two scans at each of 64 phase-encode increments surrounding the echo maximum. The pixel size in the phase-encode direction was 132 μm, and 33 μm in the read direction before zero filling. The data matrix was zero filled to 512 × 512 before Fourier transformation; no signal enhancement or digital filtering was applied to the data. Slice thickness was ~800 μm. The repetition time (T_R) was 6 s and the echo time (T_E) was 20 ms.

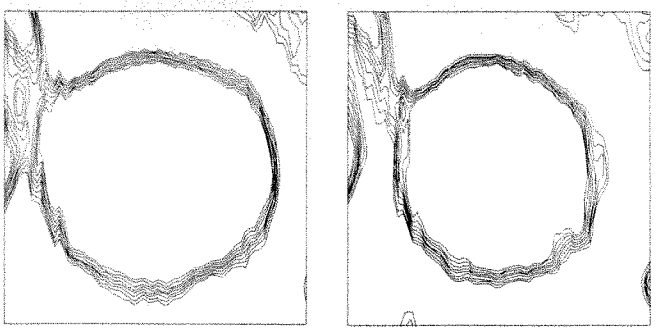

FIG. 2 Representative contour plots for cross-sectional area determinations.

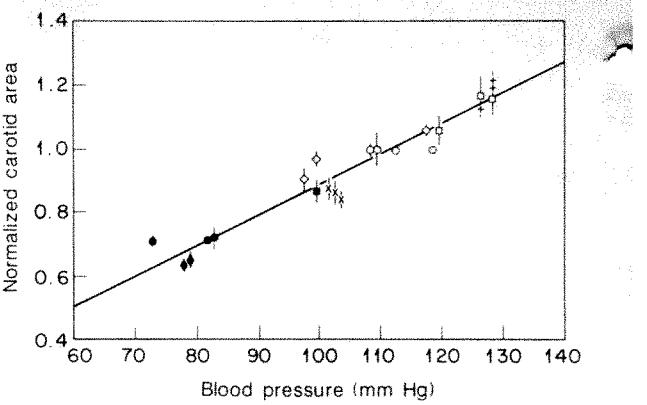

FIG. 4 Plot of the normalized cross-sectional area of the carotid artery versus blood pressure for five rats, with and without phenylephrine. The data before and after administration of the vasoconstrictor were fully reversible. ○, Control, systole; ●, control, diastole; +, drug dose 1, systole; ×, drug dose 1, diastole; □, drug dose 2, systole; ■, drug dose 2, diastole; ◇, post-drug systole; ◆, post-drug diastole.

METHODS. Blood pressure was measured using a catheter inserted into the right carotid artery. A 1.5-cm length of polyethylene tubing (0.61 mm OD, 0.28 mm ID, Clay Adams PE 10) was inserted into the artery; it was joined to a 2.9-m length of larger (0.965 mm OD, 0.58 mm ID, Clay Adams PE 50) polyethylene tubing, filled with a solution of normal saline with heparin (10 USP units ml^{-1} saline), that led out of the magnet to the pressure transducer (Spectramed P23XL). The artery was periodically flushed with heparinized saline (0.1 ml) The blood pressure typically remained stable to ~5% systole and ~8% diastole during ~5 h total experimental time. The right jugular vein of the rat was catheterized with a 2.9-m length of polyethylene tubing (PE 10). This led to a calibrated syringe pump (Sage Instruments, model 355). For an 80-g rat, phenylephrine (Sigma; 1 mg ml^{-1} in normal saline) was delivered at ~7.5 μl min^{-1}, with small variations needed to keep the blood pressure constant. For an 80-g rat, sodium nitroprusside (0.08 mg μl^{-1}; Sigma) in 5% dextrose (w/v) was delivered at 13 μl min^{-1}.

the corresponding arterial cross-sectional areas. The average distensibility was determined as 1.1% per mm Hg (range 0.67–1.36%) from the NMR data for six rats.

These NMR data provided a unique opportunity to measure non-invasively the transverse Young's modulus of the carotid artery. The Young's modulus E is a measure of the elasticity of a material and increases as the material stiffens. It is defined by E = stress/strain, or

$$E = \frac{2\pi r_0}{s} k$$

(ref. 10) where r_0 is the artery radius at zero pressure and s is the corresponding thickness of the arterial wall. For a section of artery of length l, the constant k is related to the force tangental to the arterial wall F and to the pressure P exerted by the blood on the arterial wall by

$$F = Prl = kl[2\pi(r - r_0)]$$

where r is the arterial radius at pressure P. From this expression,

$$\Delta P = 2\pi k \Delta r / r$$

Integration gives

$$(P_{\text{systole}} - P_{\text{diastole}}) = 2\pi k[\ln (r_{\text{systole}}/r_{\text{diastole}})],$$

where r_{systole} and r_{diastole} are the arterial radii at systole and diastole, respectively. Thus, we could determine k from the available NMR data and once k was obtained, calculate r_0 by setting P_{diastole} to zero. The thickness of the artery at zero pressure must be known. We measured the average thickness of an excised artery from an 80-g rat using a light microscope as 0.10 ± 0.02 mm.

The average Young's modulus was calculated as 7×10^5 dyn cm^{-2} for six rats (range 4.9×10^5–1.3×10^6 dyn cm^{-2}).

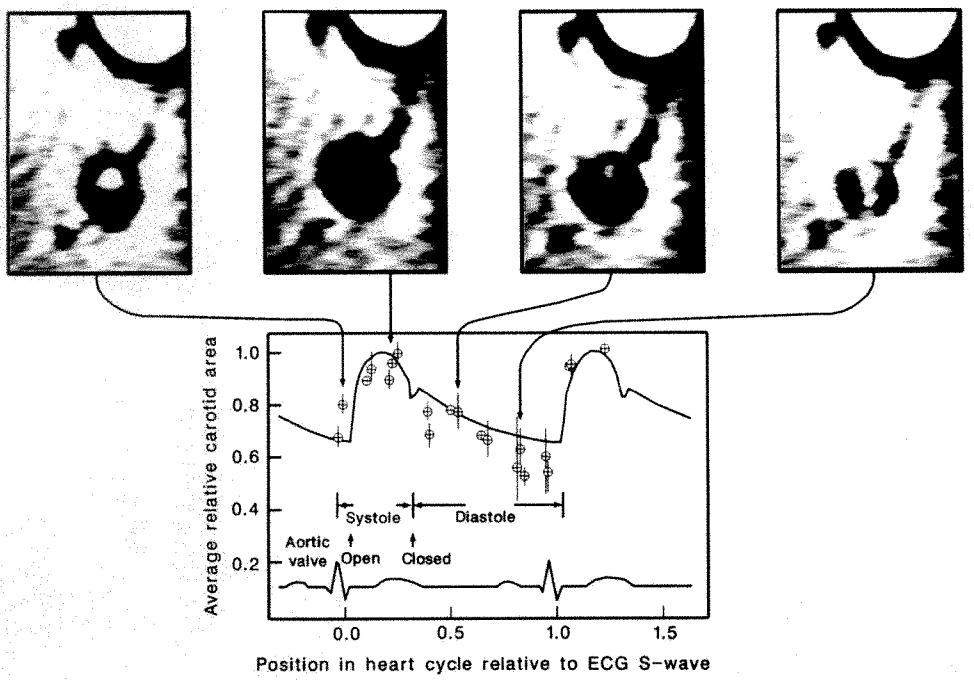

FIG. 3 Arterial cross-sectional area as a function of phase in the heart cycle. The line through the data corresponds to blood pressure in a human heart cycle and is intended only as a guide to the eye.

METHODS. Either the R- or the S wave of the electrocardiogram was used for gating. The spin-echo pulse sequence incorporated a time delay between the triggering and excitation. This delay was adjusted so that slice excitation corresponded to a known fraction of the heart cycle. The heart period (typically 150 ms) was recorded periodically and remained stable to within 3% during the 13-min experiment and ~10% during the 5 h typically required to acqure a series of data.

This can be compared with a value of 6.5×10^5 dyn cm^{-2} for the transverse modulus of an excised carotid from an 80-g rat, measured mechanically with a Rheovibron viscoelastometer. (The longitudinal Young's modulus was 3.1×10^6 dyn cm^{-2}.) The agreement between the NMR measurement of Young's modulus and the classical Rheovibron measurement is remarkable, considering the errors associated with keeping the sample moist during the viscoelastic measurements, and the assumption that the arterial thickness is identical for all arteries.

The NMR method can also be used to provide non-invasive information about the local action of vasoactive drugs. The vasoconstrictor phenylephrine affects primarily the small arterioles. As the heart beats more slowly, this results in a compensatory increase in the cardiac output. The carotid artery, therefore, must expand to accommodate this increase in volume—such an expansion may be observed directly (data not shown). Figure 4 shows the cross-sectional areas of the carotid arteries of five rats, normalized to the pre-drug systole area, plotted against the blood pressure, with and without phenylephrine. The linearity of the data shows that the drug raised the blood pressure without affecting the distensibility of the carotid artery. Similar experiments were performed with the vasodilator nitroprusside. Although the variation between rats was greater in these experiments, the data suggest that the dilation of the artery at diastole with the drug was greater than that without it.

The data shown here were obtained for the carotid artery of 80-g rats, whose arteries were ~600–800 μm in diameter. We predict that it is possible to observe changes under high-contrast conditions when there are 4–5 pixels across the artery. This would set a lower limit of 2.5–3 mm for the diameter of human vessels that can be measured accurately, given the 0.5-mm resolution so far available on whole-body machines. □

Cloned cytotoxic T cells recognize an epitope in the circumsporozoite protein and protect against malaria

Pedro Romero*, Janet L. Maryanski†, Giampietro Corradin‡, Ruth S. Nussenzweig*, Victor Nussenzweig§ & Fidel Zavala*

PROTECTIVE immunity against malaria is induced by vaccination of hosts with irradiation-attenuated sporozoites. This immunity is mediated in part by neutralizing antibodies that are directed mainly against the repeat domain of the circumsporozoite protein[1–4]. Early experiments showed, however, that B-cell-depleted mice that are immunized with sporozoites can resist challenge, indicating that T-cell effector mechanisms may also have a role in protection[5]. This idea was supported by the recent observation that protective immunity also requires T-cells expressing the CD8 antigen ($CD8^+$ T cells)[6,7], whose target is probably the developing liver-stage parasites[8–10]. Moreover, an oral *Salmonella* vaccine that expresses the circumsporozoite protein is able to protect against murine malaria in the absence of antibodies[11]. Here we report the identification of an epitope contained within amino acids 249–260 of the *Plasmodium berghei* circumsporozoite protein that is recognized by H-2Kd-restricted cytotoxic T cells[12,13]. Passive transfer into mice of cytotoxic-T-cell clones that recognize this epitope conferred a high degree of protection against challenge. These results provide the first direct evidence that $CD8^+$ T cells that are specific for a defined epitope can confer protection against a parasitic infection.

To identify epitopes in the *P. berghei* circumsporozoite (CS) protein recognized by cytotoxic T lymphocytes (CTLs), spleen cells from sporozoite-immunized BALB/c mice (haplotype H-2d) were stimulated *in vitro* in the presence of a pool of 12 synthetic peptides[14] (series I, Fig. 1) representing parts of the CS sequence. After 5–7 days of *in vitro* stimulation, the lytic activity of the spleen cells was assayed by incubation with P815 target cells (haplotype H-2d) in the presence of the individual CS peptides.

In initial experiments, the spleen cells lysed the P815 target cells only in the presence of the peptide corresponding to amino acids 249–260 (amino-acid sequence (single-letter code) NDDSYIPSAEKI). Control immune spleen cells cultured

* ^{51}Cr-labelled P815 target cells (2×10^3, in 50 μl medium), or EL-4 target cells (1×10^4, in 50 μl medium), were added to wells of V-bottom microtiter plates with or without peptide of amino acids 249–260 (1 μM). Viable spleen cells were collected after *in vitro* expansion, and added to each well in different numbers, at E:T ratios of 3:1–100:1. After 4 h of incubation at 37 °C, the plates were centrifuged and 100 μl of supernatant removed to measure chromium release. The per cent specific lysis was calculated as:

$$\frac{\text{(experimental release (c.p.m.)} - \text{spontaneous release c.p.m.)}}{\text{(total c.p.m.} - \text{spontaneous release c.p.m.)}} \times 100\%$$

Each value represents the mean of duplicate wells.
† E:T, ratio of lymphocyte effector -cells to target cells.
‡ Immune spleen cells were obtained from BALB/c mice that were immunized by multiple intravenous injections of irradiation-attenuated *P. berghei* sporozoites. Spleen cells were cultured *in vitro* for five days[25], in the presence or absence of 5 μM peptide of amino acids 249–260.

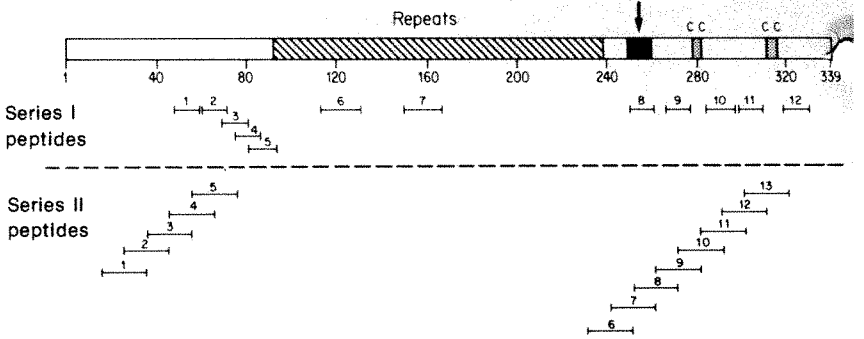

FIG. 1 Schematic representation of the *P. berghei* CS protein and related peptides. The sequences of the peptides used in these studies were taken from the deduced amino-acid sequence for the CS gene as reported[12,13,28]. Amino acids of peptides of series I are: 1, 47–58; 2, 59–70; 3, 68–80; 4, 74–85; 5, 80–92; 6, DPPPPNPNDPPPPNPND (single-letter code, dimeric repeat); 7, DPAPPNAND-PAPPNAND (single-letter code, dimeric repeat); 8, 249–260; 9, 265–276; 10, 283–296; 11, 297–308; and 12, 317–328. Amino acids of peptides of series II are: 1, 20–39; 2, 30–49;, 3, 40–59; 4, 50–69; 5, 60–79; 6, 240–259; 7, 250–269; 8, 260–279; 9, 270–289; 10, 280–299; 11, 290–309; 12, 300–319; and 13, 310–329. Amino acids of peptides of series II (except 1 and 3) have a C-terminal tyrosine that is not part of the protein sequence. Peptides of series I and II were synthesized and purified as described[17,29]. The arrow indicates the position of the cytotoxic epitope.

without peptide had no cytolytic activity. The recognition of this peptide was genetically restricted: only P815 target cells (haplotype H-2d), but not EL-4 target cells (haplotype H-2b), were specifically lysed. Naive spleen cells cultured for the same period of time with the 249–260 peptide had negligible lytic activity, indicating that the CTLs had not been primed *in vitro* by the peptide, but had been induced *in vivo* by immunization with sporozoites (Table 1).

A T-cell line was then obtained from the immune spleen cells by stimulation with the 249–260 peptide, and from this population 10 clones, designated series CS.B, were derived by limiting dilution. Four of these clones (cs.B-28, -31, -35 and -43) also killed the P815 target cells in the presence of the homologous peptide from the *P. yoelii* CS protein (amino acids 276–288), NEDSYVPSAEQI[15], differing in the three underlined amino acids from the 249–260 *P. berghei* peptide.

An independent series of four clones (series CS.C) were derived from two other immunized BALB/c mice. In this case, the spleen cells were directly stimulated under limiting-dilution conditions with a pool of a new series of thirteen 20-mer peptides (series II, Fig. 1). The series-II peptides spanned most of the sequence of the CS protein, except for the repeats, and portions of the putative signal- and anchor sequences. The peptides of series II overlapped by 10 amino acids, and differed in size from the peptides of series I. The specificity of the CS.C clones was determined by incubating each clone with the P815 target cells and pools of three peptides. If the assay was positive, it was repeated using the individual peptides. All four CS.C clones recognized two overlapping peptides (amino acids 240–259 and 250–269), which included most of the amino-acid sequence 249–260, but not other peptides of series II. None of the CS.C clones recognized the *P. yoelii* peptide of amino acids 276–288.

These findings indicate that mice bearing the H-2d haplotype recognize predominantly a single cytotoxic epitope within the CS protein. Such a limitation in the number of CTL epitopes and their MHC-dependence has been found in other viral polypeptides[16–21].

By cytofluorometry, all 14 CTL clones expressed the CD3 and CD8 antigens, but not the CD4 antigen (phenotype $CD3^+4^-8^+$). To determine the class I MHC product involved in the recognition of the epitope of amino acids 249–260, we assayed the lytic activity of the clones on L-cell fibroblasts transfected with the *Kd*-, *Ld*-, or *Dd* genes of H-2 (ref. 22). In the presence of the 249–260 peptide, all of the clones were able to lyse only the H-2*Kd*-transfected cells. The lytic activity was inhibited specifically by monoclonal antibodies against the Kd antigen but not the Ld antigen (data not shown).

Determinations of the ratio of lymphocyte effector cells to target cells (E:T) that was required for lysis were carried out for most of the CTL clones. In a representative experiment (Fig. 2*a*), we observed a 50% specific lysis of target cells at E:T ratios as low as 1.0–0.3, in the presence of 1.0 μM peptide. All clones released γ-interferon (γIFN) into the culture medium during the 4-h assay (Fig. 2*b*). In other experiments, the E:T ratio was maintained constant at 3:1, and the concentration of the 249–260 peptide was varied. For many CTL clones, 50% specific lysis was obtained in the presence of as little as 10^{-9} M peptide (Fig. 2*c*).

To determine whether the CTL clones could protect against sporozoite-induced malaria infection, nine clones were expanded and adoptively transferred into groups of naive BALB/c mice. Eighteen hours after the T-cell clone transfer, the mice were challenged by intravenous injection of *P. berghei* sporozoites. In separate experiments, the clone CS.C7 con-

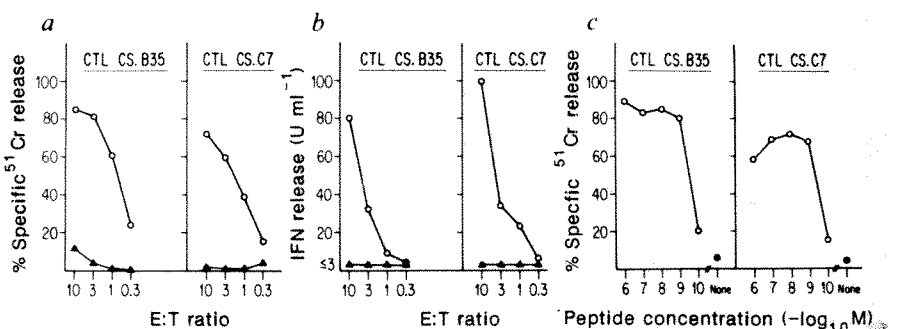

FIG. 2 Results of cytotoxic assays performed with P815 target cells and CTL clones in the presence of peptide 249–260. Specific lysis (*a*) and the production of γIFN (*b*) at different E:T ratios, in the presence of 1.0 μM peptide (○) or in the absence of peptide (▲, ●). (*c*), Specific lysis obtained with different peptide concentrations and a constant ratio of 3:1.

METHODS. A panel of 14 CS-specific CTL clones was obtained by using two different strategies. The series CS.B consisted of 10 CTL clones derived by limiting dilution of a short-term T-cell line. This T-cell line was obtained from spleen cells of sporozoite-immune mice, re-stimulated weekly with irradiated spleen cells that had been pulsed with peptide 249–260. Cells were grown in medium containing concanavalin A-induced T-cell growth factors[25]. The cloning was performed by limiting dilution, using as stimulators irradiated P815 cells pulsed with peptide 249–260[26]. Once the clones were established, they were maintained by weekly re-stimulation with the same stimulator cells in addition to peptide. The four clones of the series CS.C. were obtained directly by limiting dilution of sporozoite-immune spleen cells, without previous *in vitro* expansion. The P815 stimulator cells were pulsed with a mixture of thirteen 20mer peptides (series II, Fig. 1) for 1 h at 37 °C. These clones were expanded for the first three passages with the same mixture of peptides until their epitope specificity was determined. Cells were then maintained by weekly re-stimulation with P815 cells pulsed with peptide 249–260. The CTL assay was performed as described in the footnote to Table 1. To measure the production of γIFN during the CTL assay, an aliquot of 30 μl was removed from the supernatant after 4 h incubation. γIFN content was measured using a previously described immunoassay[30].

sistently conferred a high degree of protection to the recipient mice (Table 2). Two other clones (CS.C1 and CS.C11) were also protective. Protection was obtained with challenge doses of 2×10^3–10^4 sporozoites when 2×10^7 cells of the CS.C7 clones were transferred. Protection was species-specific, as indicated by the failure of the CS.C7 clones to protect against challenge with 500 sporozoites of *P. yoelii*, a more infective rodent malaria parasite than *P. berghei*. This result is in agreement with the lack of *in vitro* recognition of the homologous *P. yoelii* peptide by the CS.C7 CTL clones (data not shown). Furthermore, the protective effect was also stage-specific; the CS.C7 clone conferred no protection against challenge with 2,000 red blood cells infected with *P. berghei*.

Partial protection, which needs to be confirmed by additional experiments, was observed with three other clones (CS.C3, CS.B43 and CS.B18). No protection was observed with clones CS.B35, CS.B28 and CS.B83. Although differences in the protective ability of CTL clones have been reported in another system[23], the basis of this functional heterogeneity remains unclear. Variation in the fine specificity of the clones, or the loss of 'homing' receptors after long periods of *in vitro* culture may be responsible for this phenomenon[24]. Furthermore, the method used in this study to evaluate the efficacy of the adoptive protection, that is the detection of patent infection, is very stringent and is based on an all-or-nothing effect. Even if a large number of the liver-stage parasites had been inhibited by the T-cell clones, a full-blown infection of the erythrocytes would result.

The most probable targets of the protective CTL clone are the intrahepatocytic stages of malaria parasites, the protection being mediated either through a direct recognition of the infected cells, or by the release of lymphokines. Gamma-IFN, a product of T-cells, has a potent inhibitory effect on the development of liver-stage parasites[8,9]. But a recent study has shown that spleen cells from mice that have been immunized with irradiated sporozoites can eliminate *P. berghei* parasites from hepatocytes *in vitro*, and that this effect cannot be inhibited by a monoclonal antibody against γIFN (ref. 10).

The processing of polypeptide antigens and their presentation to T-cells that recognize class-I-restricted epitopes seem to result from the intracytoplasmic degradation of the antigens (for a review see ref. 14). Sporozoites, however, are not localized in the cytoplasm, but are found in endocytic vesicles. Perhaps the CS protein leaks into the cytoplasm of the host cells (hepatocytes and macrophages) and enters the 'endogenous' pathway of antigen processing. Alternatively, antigens of sporozoites, and perhaps of other microbes found in endocytic vesicles, may follow a different processing pathway. A better understanding of these mechanisms should facilitate the design of immunogens and vaccines which aim at inducing both antibodies and $CD8^+$ cytotoxic T cells.

Our results are in agreement with earlier findings showing that cytotoxic-T-cell epitopes are contained within the CS protein of *P. falciparum*[21]. More important, we demonstrate that these epitopes can be the target of cell-mediated immunity, and that $CD8^+$ T cells that are specific for a single epitope can confer protection against a parasitic infection. □

TABLE 2 Effect of passively transferred CS-specific cytotoxic T-cell clones on sporozoite challenge

Cells transferred* (no. cells $\times10^6$)	Challenge†	No. protected/ total challenged	% Mice protected
Experiment 1			
C7 (18)	*P. berghei*	5/5	100
C1 (40)	*P. berghei*	16/21	76
B35‡ (30)	*P. berghei*	0/5	0
Normal spleen cells (40)	*P. berghei*	0/6	0
Experiment 2			
C11 (20)	*P. berghei*	5/5	100
Normal spleen cells (20)	*P. berghei*	0/5	0
Experiment 3			
C7 (25)	*P. berghei*	5/5	100
C7 (5)	*P. berghei*	0/5	0
Experiment 4			
C7 (20)	*P. berghei*	5/5	100
Normal spleen cells (20)	*P. berghei*	0/5	0
C7 (20)	*P. yoelii*	0/5	0
Normal spleen cells (20)	*P. yoelii*	0/5	0
Experiment 5			
C7 (20)	*P. berghei*	5/5	100
Normal spleen cells (20)	*P. berghei*	0/5	0
C7 (20)	*P. berghei* (blood forms)	0/5	0

* *P. berghei* CS-specific cytotoxic clones were maintained in culture by weekly re-stimulation as described[26]. Groups of age-matched (8–10-week-old) female BALB/c mice were injected intravenously with each of the CTL clones collected 7 days after re-stimulation with antigen. As controls, other groups of mice were injected with normal spleen cells. Immediately before transfer, cells were resuspended in culture medium (0.5 ml) without serum and containing 10^3 U human recombinant interleukin-2. A second dose (10^3 U) of interleukin-2 was administered intraperitoneally 16 h after cell transfer. The mice were challenged 18 h after the cell transfer by intravenous injection of sporozoites. A final dose of 10^3 U interleukin-2[27] was administered intravenously 24 h after sporozoite challenge. Thin blood smears were prepared daily between day 3 and day 12 after challenge, stained with Giemsa and examined by light microscopy to detect parasitized red blood cells. Protection was defined as absence of parasitaemia.

† In experiments 1, 2, 3 and 4, the mice were challenged with 2,000 *P. berghei* sporozoites. In experiment 5 they were challenged either with 10,000 *P. berghei* sporozoites or with 2,000 infected red blood cells obtained from a *P. berghei*-infected mouse. In experiment 4, some groups of mice were challenged with 500 *P. yoelii* sporozoites.

‡ Mice injected with clones CS.B28 (17×10^6 cells per mouse), B83 (26×10^6) and CS.B35 (20×10^6) were not protected against sporozoite challenge. Partial protection, which needs to be confirmed in additional experiments, was obtained with three other clones (CS.C3, CS.B43 and CS.B18).

An explanation for the protective effect of the MHC class II I-E molecule in murine diabetes

INSULIN-DEPENDENT diabetes mellitus is widely believed to be an autoimmune disease[1]. Recent onset diabetics show destruction of insulin-secreting pancreatic β-cells associated with a lymphocytic infiltrate (insulitis)[2], with autoantibodies to β-cells being found even before the onset of symptoms[3]. Susceptibility to the disease is strongly influenced by major histocompatibility complex (MHC) class II polymorphism in both man[4] and experimental animal models such as the non-obese diabetic (NOD) mouse[5]. As MHC class II molecules are usually associated with dominant immune responsiveness, it was surprising that introduction of a transgenic class II molecule, I-E, protected NOD mice from insulitis and diabetes[6]. This could be explained by a change either in the target tissue or in the T cells presumed to be involved in β-cell destruction. Recently, several studies have shown that I-E molecules are associated with ontogenetic deletion of T cells bearing antigen/MHC receptors encoded in part by certain T-cell receptor *Vβ* gene segments[7–11]. To determine the mechanism of the protective effect of I-E, we have produced cloned CD4$^+$ and CD8$^+$ T-cell lines from islets of recently diabetic NOD mice. These cloned lines are islet-specific and pathogenic in both I-E$^-$ and I-E$^+$ mice. Both CD4$^+$ and CD8$^+$ cloned T cells bear receptors encoded by a *Vβ5* gene segment, known to be deleted during development in I-E expressing mice[10]. Our data provide, therefore, an explanation for the puzzling effect of I-E on susceptibility to diabetes in NOD mice.

Studies of insulin-dependent diabetes mellitus (IDDM) in NOD mice, BioBreeding (BB) rats and man all demonstrate a pathogenic role for T cells, probably by direct cytotoxic effects on β-cells. In addition, it is clear that both CD4$^+$ and CD8$^+$T cells are required to transfer diabetes to NOD mice[12,13]. To further characterize the specific T cells involved in the immunopathogenesis of IDDM in NOD mice, we have isolated and cloned by limiting dilution a number of T-cell lines from the islets of recently diabetic NOD mice. Islet-specific cloned T-cell lines are propagated by feeding with NOD islets and exogenous interleukin-2 (IL-2). Among the cloned lines we have recovered, several respond specifically to NOD islets and not to NOD spleen cells (Fig. 1). The data shown in this paper all derive from a single CD4$^+$ and a single CD8$^+$ cloned T-cell line. Identical results have been obtained with three other CD4$^+$ T-cell lines and one other CD8$^+$ T-cell line (data not shown). Further analysis shows that the CD4$^+$ cloned T cells do not respond significantly to islets from BALB/c mice, differing from NOD mice at many loci, including MHC. Unlike the one previously reported murine islet-specific cloned CD4$^+$ T-cell line[14], the response of our CD4$^+$ cloned lines to islets did not require the addition of syngeneic feeder cells. CD8$^+$ cloned lines do respond to BALB/c islets; BALB/c and NOD are similar or identical at the class I MHC locus H-2K^d, perhaps accounting for this result[5]. B10.BR (H-2^k) islets stimulate neither cloned line significantly (data not shown). Thus, both CD4$^+$ and CD8$^+$ cloned lines appear to be islet-specific and MHC restricted. Because BALB/c mice are I-E positive, and because (NOD × BALB/c)F_1 hybrid mice develop neither insulitis nor diabetes, which is consistent with the results in I-E transgenic NOD mice, we asked whether the putative islet autoantigens recognized by our cloned T-cell lines were expressed on these islets. As can be seen (Fig. 1), both CD4$^+$ and CD8$^+$ cloned T cells respond to (NOD × BALB/c)F_1 islets. This suggests that the protective effect of I-E expression is not due to an absence of stimulatory autoantigens on islet cells.

These cloned T-cell lines have been tested for their ability to transfer disease to sub-lethally irradiated young NOD mice, according to the protocol of Miller *et al*[13] for polyclonal T cells. As can be seen in Fig. 2*a*, neither CD4$^+$ nor CD8$^+$ clones injected alone cause significant insulitis. As predicted by earlier studies using uncloned T cells[12,13] and by injection of antibodies against CD4 (refs 15, 16) and CD8 (ref. 17), however, the mixture of islet-specific CD4$^+$ and islet-specific CD8$^+$ clones causes intense insulitis by 28 days in most islets of all mice sampled. This mixture of cloned T cells causes loss of cells containing insulin immunoreactivity from islets invaded by lymphocytes in these mice (data not shown), as well as glycosuria on occasion. These results suggest that the transferred T cells markedly impair β-cell function. The fraction of cells found in the islets of such mice derived from the injected cloned T cells is not known. In parallel

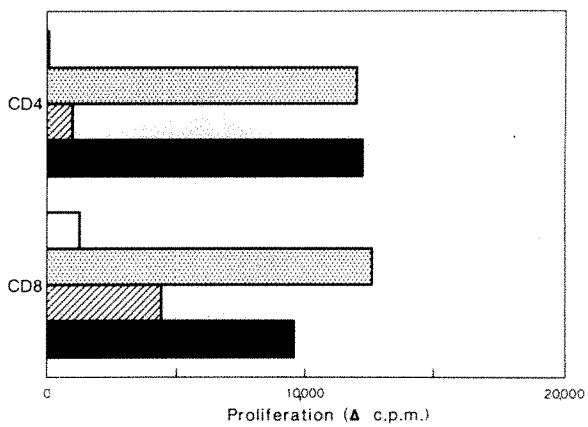

FIG. 1 NOD mouse islet derived CD4$^+$, CD8$^-$ and CD8$^+$, CD4$^-$ cloned T-cell lines demonstrate islet specificity and MHC restriction. Proliferation assays were used to determine the response of the T-cell clones using the following stimulators: NOD spleen cells (open bars), NOD islets (spotted bars), BALB/c islets (striped bars), and (NOD × BALB/c)F1 islets (black bars). Note that both cloned lines respond equally to NOD islets (I-E$^-$) and (NOD × BALB/c)F1 islets (I-E$^+$).

METHODS. Islet-specific T-cell clones were generated from islets obtained from newly diabetic NOD female mice. T cells were expanded in recombinant (r) IL-2 (10 U ml^{-1}) in Click's EHAA medium with 10% FCS. Every 21 days, rIL-2 was removed for 2 days. Cloned lines were stimulated with mitomycin-C treated NOD islets for two days, after which cells were expanded in rIL-2-containing medium. Cells were cloned by limiting dilution. Mouse islets were isolated by the method of Prowse *et al*[29]. In the proliferation assay, mitomycin C-treated splenocytes (10^5) or islets (10) are cultured with islet specific T-cell clones (10^4) in 0.2 ml Click's medium and 5% FCS in 96-well round-bottomed microtitre plates. After 48 h, rIL-2 (5 U ml^{-1}) is added to the wells, and at 96 h of total incubation, a terminal 16 h pulse with 1 μCi [^{3}H]thymidine (6.7 Ci mmol^{-1}; ICN) was added to the cultures. The mean c.p.m. for thymidine incorporation are calculated from duplicate cultures.

‡ To whom correspondence should be addressed.

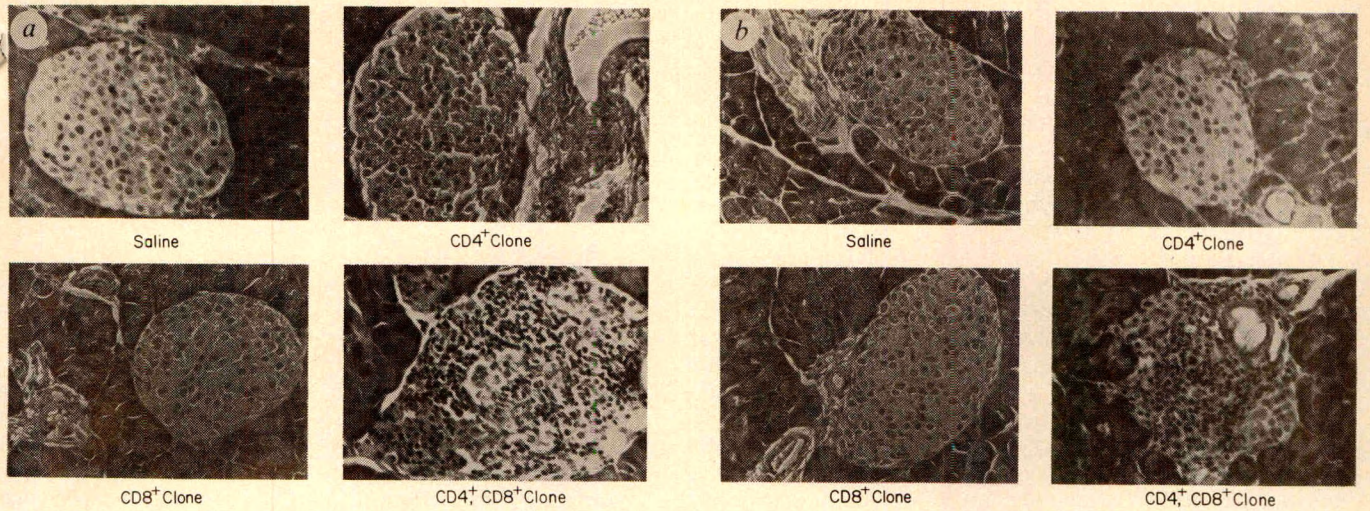

FIG. 2 A combination of a $CD4^+$ and a $CD8^+$ islet specific T-cell clone is required to produce insulitis in irradiated NOD (*a*) and (NOD × BALB/c)F1 (*b*) recipient mice. Representative pancreatic sections are shown from four treatment groups: saline (upper left), $CD4^+$ clone alone (upper right), $CD8^+$ clone alone (lower left), and a mixture of a $CD4^+$ and a $CD8^+$ clone (lower right). Insulitis, massive lymphocytic infiltration into the islet, is seen only in the groups that received a mixture of the two cloned lines.

METHODS. Female NOD and (NOD × BALB/c)F1 mice, 7–8 weeks old, were given whole-body irradiation (700 rads) before being injected intravenously with 5×10^6 cloned T cells in 0.3 ml saline. Recipient mice were killed 4 weeks after treatment for histopathology. The tissue was fixed in buffered formalin, paraffin-embedded, sectioned and stained with haematoxylin and eosin.

studies, similar results are found in $(NOD \times BALB/c)F_1$ irradiated recipients (Fig. 2*b*), again arguing against an effect of I-E on autoantigen expression in NOD islets. These studies also show that prior inflammation of the islets is not required to obtain stimulation of our cloned T-cell lines *in vivo* or *in vitro*. Thus, the responses of $CD4^+$ T cells are likely to be directed against secreted β-cell products processed and presented by antigen-presenting cells normally residing in the islet.

As I-E expression appears to be unable to protect islets from autoimmune attack by cloned, MHC-restricted, islet cell-specific T cells, we have examined an alternative hypothesis. It is now well established that expression of I-E is associated with the deletion during intrathymic ontogeny of T cells whose receptors are encoded by certain $V\beta$ genes[7,10,11]. To determine if such deletional effects might explain the protective effect of I-E on diabetes in NOD mice, we determined the $V\beta$ genes expressed by the receptors on our cloned T-cell lines. As can be seen in Fig. 3, both the $CD4^+$ and the $CD8^+$ cloned T-cell lines express T-cell receptors that have β-chain variable regions which are partially encoded by $V\beta5$; this was true of 3 of 3 other $CD4^+$ and 6 of 12 other $CD8^+$ cloned, islet-specific T-cell lines tested. It has recently been shown that T cells expressing $V\beta5$ are ontogenetically deleted in I-E expressing mice[10]. Also, we have shown that NOD mice express $V\beta5$ on ~5% of their T cells, whereas $(NOD \times BALB/c)F_1$ mice express $V\beta5$ on very few T cells (~1%). Finally, preliminary adoptive transfer experiments of splenic T cells from recently diabetic mice to irradiated young NOD recipients[13] gives diabetes in all recipients, whereas depletion of $V\beta5$-bearing T cells from this population gives almost no diabetes (E-P.R., O.K., R.S.S. and C.A.J., unpublished data). Thus, if the cloned, pathogenic T-cell lines we have isolated are representative of the cells involved in β-cell destruction in NOD mice, as seems likely from the above studies, then one can understand the protective effect of I-E.

Two other issues are worth noting. First, the mechanism by which T cells, distinguishable only by expression of the T-cell antigen receptor (TCR) encoded by particular $V\beta$ gene segments, are deleted by I-E molecules is unclear. However, it is probable that it is not I-E alone which is responsible for the deletional effects, as similar effects are observed in deletion by *Mls* locus polymorphisms[8,9]. Although the precise nature of the *Mls* locus product is unknown, a highly analogous situation is observed with certain bacterial proteins, such as the *Staphylococcal* enterotoxins[18–20] (J. Yagi and C.A.J, manuscript submitted). These proteins seem to act by binding to the outer face of the class II molecule and to the outer face of the $V\beta$-encoded segment of the TCR (ref. 19). It has also been shown that T cells expressing a receptor encoded by $V\beta17a$ do not respond to I-E expressed on transfected L cells, although they do respond

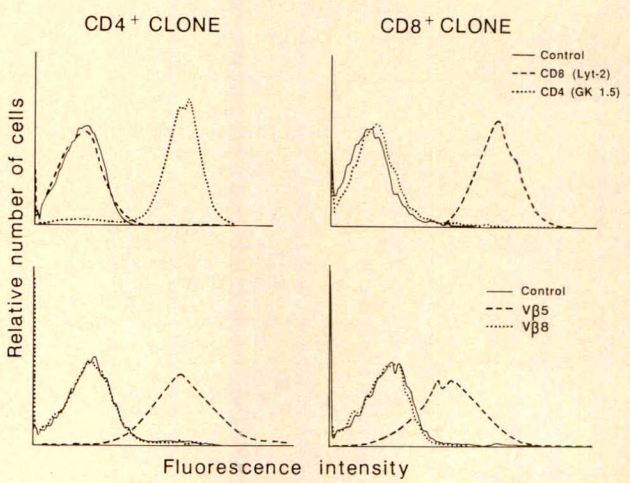

FIG. 3 Both $CD4^+$, $CD8^-$ and $CD8^+$, $CD4^-$ islet specific T-cell clones express T-cell receptors with β-chain variable regions which are encoded by $V\beta5$. Immunofluorescent analysis was carried out using the following biotin-conjugated monoclonal antibodies: Controls, FITC-Avidin alone; upper panels, anti-CD8, anti-CD4; and lower panels, anti-$V\beta5$ (MR9-4) (O.K. & E. Palmer, manuscript submitted) and anti-$V\beta8$ (F23.1) (ref. 30).

METHODS. Biotin-conjugated antibodies, at optimum concentrations, were added to 10^6 T cells for 30 min at 4 °C in phospate-buffered saline containing 2% FCS and 0.1% sodium azide (staining buffer). After washing with staining buffer, cells were stained with FITC-Avidin for 30 min at 4 °C. Washed cells were analysed on a FACS 440. Cell number is displayed against a 3.7 log unit axis of fluorescence intensity.

to I-E expressed on B cells[21]. Such cells are ontogenetically deleted in I-E positive mice. These studies suggest that all such deletional events may involve *Mls*-like molecules. Presumably the I-E molecules expressed in NOD transgenic mice delete Vβ5-bearing cells by such a mechanism and thus protect the animal from autoimmune β-cell attack.

The second issue involves the apparent protective effect of certain HLA-DR alleles in human IDDM. It is well known that HLA-DR2 is negatively associated with IDDM in man[22]. Could this class II molecule be deleting potentially autoreactive T cells? This question is worth examining, even though current evidence indicates that Vβ deletion is not a common event in man[23]. Rather, it has been argued that the protective effect of certain HLA-DR alleles is due to linkage disequilibrium with a non-susceptible allele at HLA-DQ (refs 4, 24). This raises an alternative intriguing possibility, namely, that linkage disequilibrium in HLA is maintained so that the deletion of certain TCRs in people of each HLA-DR genotype leaves residual TCRs that can interact effectively with the linked HLA molecules to generate protective immunity. It is worth noting that the protective effect of HLA-DR2 is seen in heterozygotes as well, indicating that this effect is dominant. Deletion of potentially autoreactive T cells in such individuals is, therefore, a possibility.

One can argue that autoimmune diseases are diseases of receptor repertoire, in which lymphocytes bearing autoreactive receptors are activated and cause tissue damage. The studies reported here are consistent with this proposal. Similarly, recent studies have shown a remarkable homogeneity in autoreactive T cells in experimental allergic encephalomyelitis[25,26], an induced autoimmune disease of mice, and in rheumatoid arthritis, a spontaneous autoimmune disease in man[27]. That diabetes may fall into this same group further supports the notion that the outgrowth of 'forbidden clones' may underlie many such diseases[28]. This raises the hope that anti-receptor immunotherapy may be more beneficial than would be predicted on the basis of effects of anti-idiotypic antibody administration in conventional immune responses. □

ACKNOWLEDGEMENTS. The authors would like to thank Masakazu Hattori for supplying the NOD mice from which our colony derived, Satyajit Rath for help with histopathology, Janet Williams, Denise Scaringe, Pat Conrad and Cara Wunderlich for technical assistance, Rocco Carbone for FACS analysis and Liza Cluggish for secretarial help. These studies were supported by the Juvenile Diabetes Foundation (C.A.J.), the American Diabetes Association (R.S.S.) and by the Howard Hughes Medical Institute. E.-P.R. was supported by an NIH training grant.

Myosin I is located at the leading edges of locomoting *Dictyostelium* amoebae

MOVEMENT of a eukaryotic cell along a substrate occurs by extension of lamellipodia and pseudopodia at the anterior and retraction at the posterior of the cell. The molecular and structural mechanisms of these movements are uncertain. *Dictyostelium discoideum* contains two forms of myosin. Here we show by immunofluorescence microscopy that non-filamentous myosin I occurs at the leading edges of the lamellipodial projections of migrating *Dictyostelium* amoebae, which are devoid of myosin II, whereas filamentous myosin II is concentrated in the posterior of the cells. On the basis of these locations of the two forms of myosin and their known biochemical and biophysical properties, we suggest that actomyosin I may contribute to the forces that cause extension at the leading edge of a motile cell, while the contraction of actomyosin II at the rear squeezes the cell mass forward. Myosin I isozymes might have similar roles in metazoan cells, for example at the leading edges of neuronal growth cones, and in the extension

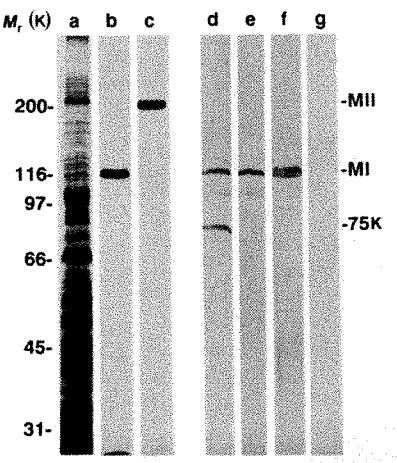

FIG. 1 Lanes *a–c*, Coomassie blue-stained gels of total *Dictyostelium* cell lysate (lane *a*), purified myosin I (lane *b*) and purified myosin II (lane *c*). Lane *d*, Immunoblot of a cell lysate probed with DM1, which recognizes peptides of 117K (myosin I, heavy chain) and 75K. Lane *e*, Immunoblot of a cell lysate probed with pDM1 (DM1 after adsorption with partially purified 75K protein). Lanes *f* and *g*, Immunoblots with partially purified 75K protein). Lanes *f* and *g*, Immunoblots of purified myosin I (lane *f*) and myosin II (lane *g*) with pDM1. M_rs for migrating standard proteins are indicated (in thousands) on the left; positions of myosin II (MII) and myosin I (MI) heavy chains, and 75K protein are shown on the right.

METHODS. Myosin I was purified from *D. discoideum* (strain AX-3) essentially as described for *Acanthamoeba* myosin I[20]. Purified myosin II[22] was a gift from E. Kuczmarski. The 75K polypeptide was partially purified by chromatography on DE-52 (Whatman), hydroxyapatite (BioRad), and MonoQ (Pharmacia). A New Zealand white rabbit was immunized by two injections, each containing 200 μg myosin I in Freund's adjuvant and spaced three weeks apart, and was bled 10 days after the second injection. The antiserum so obtained (DM1) was adsorbed (pDM1) with the 75K polypeptide immobilized on nitrocellulose membranes. After separation by SDS-PAGE[23] and transfer to nitrocellulose membranes[24], the proteins were immunoblotted. Nitrocellulose replicas were incubated in DM1 and pDM1 diluted 800-fold. Primary antibodies were visualized after incubation with peroxidase-conjugated goat anti-rabbit IgG (Boehringer Mannheim).

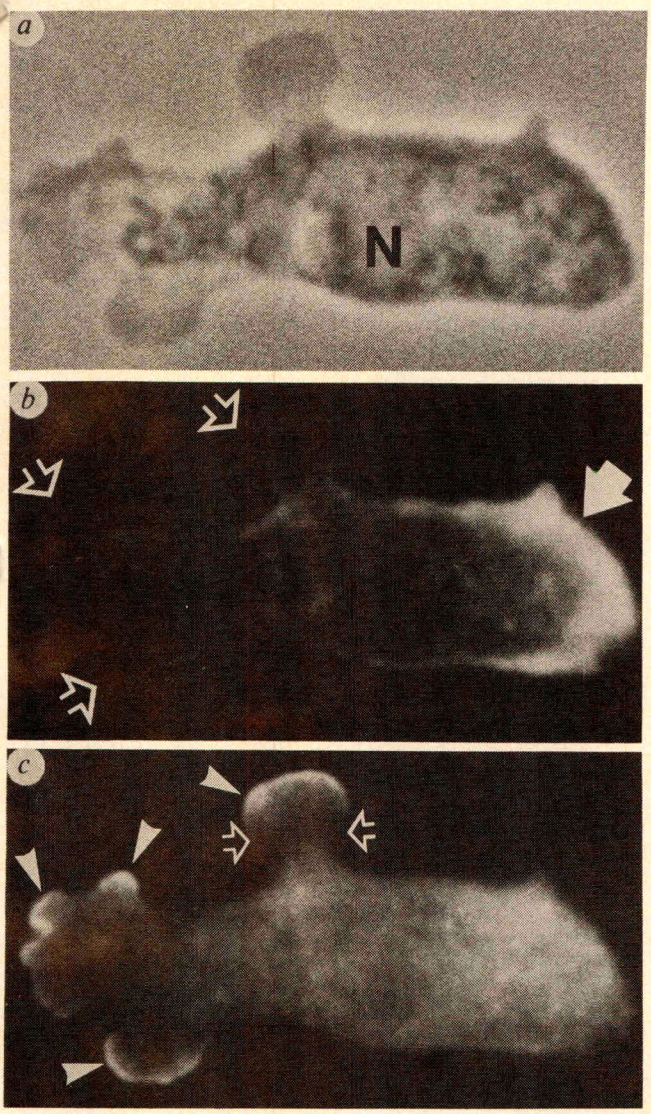

FIG. 2 Differential localization of myosin I and myosin II in a migrating *Dictyostelium* amoeba. *a*, Phase-contrast image of a representative cell migrating from right to left. The cell has formed one lamellipodium and two pseudopodia. *N*, denotes the nucleus. *b* and *c*, Immunofluorescence micrographs of the same cell stained for myosin II (*b*) and for myosin I (*c*). Magnification, ×3,450

METHODS. *D. discoideum* amoebae (strain NC4) were plated on coverslips and prepared for immunofluorescence by the 'agar-overlay' technique[10]. Briefly, samples were fixed for 5 min at −15 °C with 1% formaldehyde in absolute methanol and washed with PBS solution (137 mM NaCl, 2.7 mM KCl, 1.5 mM KH_2PO_4, 8.0 mM Na_2HPO_4, pH 7.3) for 10 min. After removing the agarose, samples were incubated for 30 min at 37 °C in a 1:1 mixture of pDM1 (rabbit anti-myosin I) diluted 1:80 in PBS, and DM2 (mouse monoclonal IgG against myosin II) at 2 μg ml^{-1} in PBS. After washing with PBS for 10 min, the sample was stained for 30 min at 37 °C with a mixture of fluorescein isothiocyanate-labelled goat anti-rabbit IgG, $F(ab')_2$ (Sigma) and tetramethylrhodamine isothiocyanate-labelled goat anti-mouse IgG (Southern Biotechnology Associates), both diluted 1:25 (final) in PBS. Non-specific staining was eliminated by carefully selecting among the commercially obtained second antibodies and by pre-adsorbing them with cell lysate[14]. Samples were washed with PBS, mounted in a mixture of 10%(w/v) 1,4-diazabicyclo[2,2,2]octane, 30% glycerol and 20% polyvinylalcohol in PBS[14], and observed under a Zeiss Photomicroscope III equipped with Plan Neofluar ×40 (N.A. 0.9), Plan Apo ×63 (N.A. 1.4) and Neofluar ×100 (N.A. 1.3) objective lenses. Micrographs were taken on Tmax-400 film (Kodak) developed with Diafine (Acufine).

of lamellipodia and pseudopodia of leukocytes, macrophages and fibroblasts.

Dictyostelium amoebae, which chemotax as elongate, polarized cells, provide a favourable system for studying the role of actomyosin in cell motility[1]. Actin[2,3] and two forms of myosin have been purified from *Dictyostelium:* myosin II (ref. 4) is a conventional myosin of native relative molecular mass (M_r) ~ 550,000 (550K) that self-assembles into bipolar filaments analogous to the thick filaments of the skeletal muscle sarcomere. Myosin I (ref. 5) by contrast, is a single-headed globular protein of M_r ~ 140K which is incapable of forming filaments. It is very similar to the much more extensively characterized myosin I isozymes from *Acanthamoeba*[6]. Both myosins I and II are mechanochemical enzymes which generate force through the hydrolysis of ATP when complexed with F-actin[6].

Recently two genetically engineered myosin II-deficient strains of *Dictyostelium*[7,8] were found to be defective in cytokinesis, but capable of phagocytosis and limited chemotaxis.

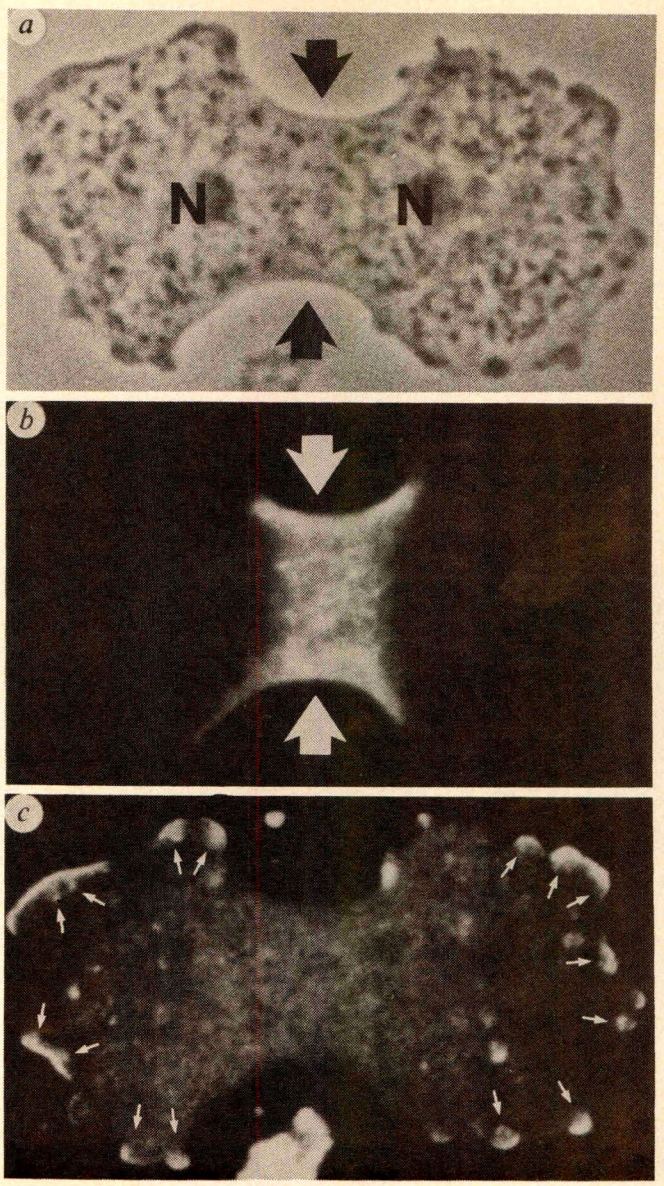

FIG. 3 *Dictyostelium* amoeba during cytokinesis. *a*, Phase-contrast micrograph of a cell with a typical cleavage furrow (arrows) and surface projections at its poles. *N*, denotes nuclei. *b* and *c*, Immunofluorescence micrograph of the same cell stained for myosin II (panel *b*) and for myosin I (panel *c*). Magnification, ×3,800

The velocity of amoeboid movement of these cells is substantially impaired, but the rate of formation of pseudopodia is relatively normal[9], although the pseudopodial area and growth rate are diminished. These results indicate that myosin II is required for normal translocation but is not essential for phagocytosis or the extension of pseudopodia at the leading edge. We were therefore interested to investigate the intracellular distribution of myosin I in normal motile cells.

We used two antibodies in the studies illustrated here. DM2, a monoclonal antibody against myosin II (ref. 10), recognizes only the myosin II heavy chain in immunoblots of total cell extracts and does not react even with large amounts of purified myosin I (data not shown). DM1, the antiserum raised against purified *Dictyostelium* myosin I, recognizes two polypeptides in immunoblots of total cell lysates, the 117K myosin I heavy chain and an unidentified 75K polypeptide (Fig. 1, lane *d*). Specific anti-myosin I serum (pDMI) (Fig. 1, lane *e*) was obtained by adsorption of DMI with a partially purified preparation of the 75K polypeptide. We found that pDM1 does not recognize myosin II on immunoblots of cell lysates or of the purified protein (Fig. 1, lanes *e* and *g*).

Figure 2*a* shows a phase-contrast image of a typical migrating cell. As we expected from earlier work[10–12], myosin II is concentrated in the posterior cortical region (Fig. 2*b*; large arrow). A limited number of myosin filaments are scattered throughout the cytoplasm, but essentially no myosin II is detected in the lamellipodia or pseudopodia (Fig. 2*b*; open arrows). In marked contrast, myosin I is concentrated in the submembranous cortex at the leading edge of lamellipodia and pseudopodia (Fig. 2*c*; arrowheads). The intensity of staining of myosin I, and the distance it extends in from the margin of the cell, varies in different projections, possibly reflecting the dynamic nature of the anterior of a migrating amoeba. A substantial amount of myosin I is also diffusely distributed in the cytopolasm, particularly in the posterior of the cells, but regions behind the leading edge contain little or no myosin I (Fig. 2*c*; open arrows).

Results were identical when we used two antisera raised against *Acanthamoeba* myosin I and a second antiserum against *Dictyostelium* myosin I. Each of these four antisera reacts strongly with myosin I and very weakly with different patterns of lower molecular weight peptides on immunoblots of total cell lysates; other bands are almost undetectable with the second *Dictyostelium* myosin I antiserum, and adsorption with total amoeba protein minus myosin I has no effect on the immunoblots. Cells did not stain with pre-immune serum or with the second antibodies alone (goat anti-rabbit

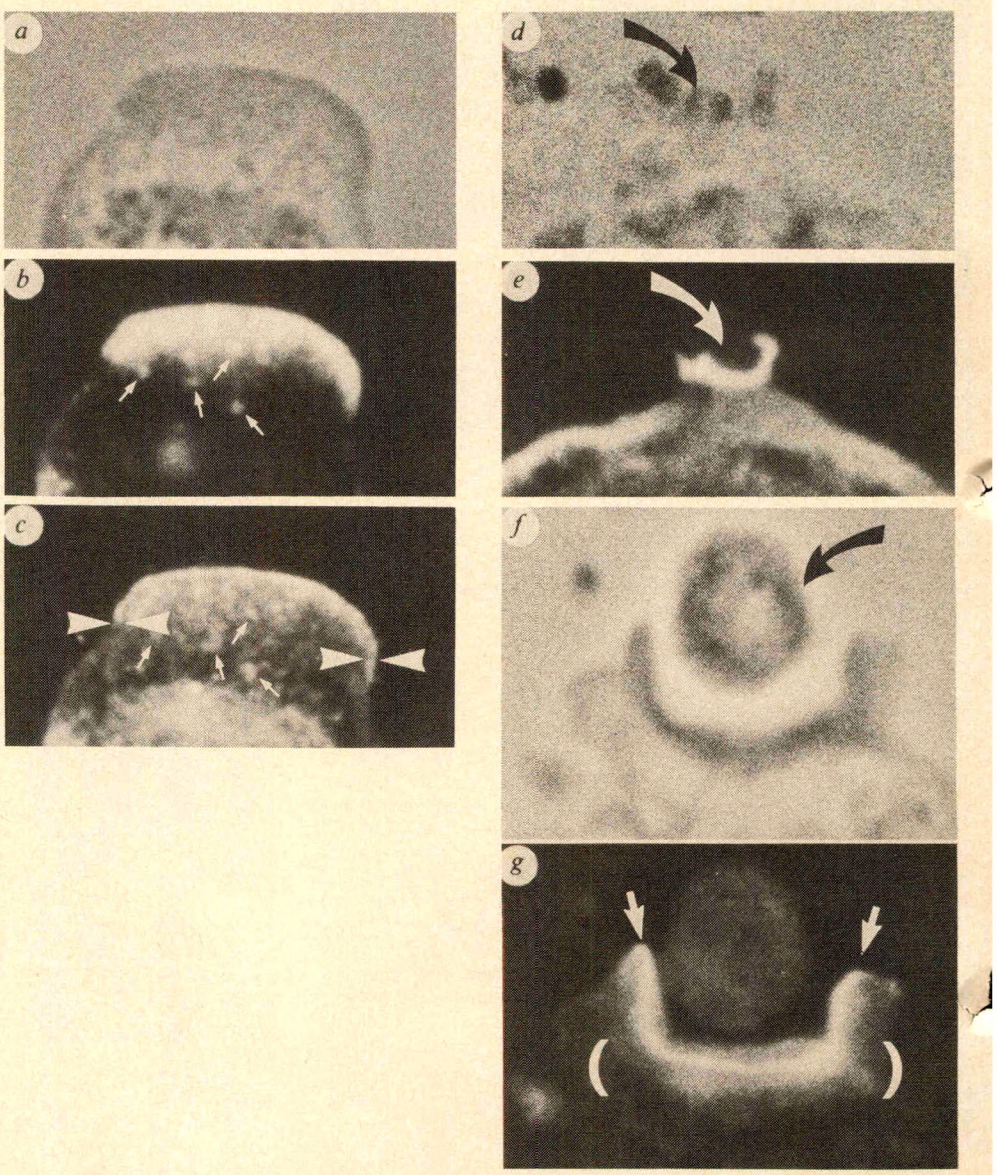

FIG. 4 Localization of myosin I at the leading edge. *a*, Phase-contrast and *b* *c*, fluorescence micrographs of the same lamellipodium stained for *F-actin* (*b*) and myosin I (panel *c*). Magnification, ×10,000. *d* and *e*, Localization of F-actin in the phagocytic cup. *d*, Phase-contrast micrograph of a phagocytic cup internalizing bacteria (arrow). *e* Fluorescence micrograph of the same region stained for F-actin. Magnification, ×6,000X. *f* and *g*, Localization of myosin I in the phagocytic cup. *f*, Phase-contrast micrograph of a phagocytic cup of one amoeba internalizing what appears to be a fragment of another amoeba (arrow). *g*, Immunofluorescence micrograph of the same region stained for myosin I. Magnification, ×6,700.
METHODS. Sample preparation and microscopy were as described in the legend to Fig. 2, except that the sample shown in *a–c* was incubated for 20 min at 37 °C with rhodamine-phalloidin (Molecular Probes), diluted 1:5 in PBS after staining with pDMI and its secondary antibody; also, the sample shown in *d* and *e* was stained with only rhodamine-phalloidin.

and goat anti-mouse IgG). Each of the images in Figs 2–4 is characteristic of more than 1,000 cells and we confirmed these observations by through-focus images of cells that had not been flattened.

Amoebae undergoing cytokinesis form a cleavage furrow and distinctive local pseudopodial projections (Fig. 3*a*). As before[10,12], myosin II is concentrated in the cleavage furrow of the dividing cell (Fig. 3*b*; arrows). Myosin I does not accumulate in the cleavage furrow (Fig. 3*c*) but is concentrated in the pseudopodia at the two poles of the dividing cell (Fig. 3*c*; small arrows). The diffuse cytoplasmic fluorescence of myosin I is less intense in the polar regions of dividing cells, which may correspond to the exclusion of myosin I from the regions behind the leading edge of migrating amoebae.

Fluorescence localization of F-actin with rhodamine-labelled phalloidin confirms earlier reports[10,13,14] of its existence in the lamellipodia and pseudopodia projecting from the anterior of the cells and in the posterior cortical regions (data not shown). Interestingly, double fluorescence staining of lamellipodia of migrating cells (Fig. 4*a*) shows that myosin I is, for the most part, restricted to a narrow zone at the leading edge (Fig. 4*c*), whereas F-actin occupies a broader zone extending further into the body of the cell (Fig. 4*b*). Small foci behind the leading edge stain for both F-actin and myosin I (Fig. 4*b* and *c*; small arrows).

Formation of a cortical projection is an early step in the ingestion of particles by these amoebae. The 'phagocytic cup' contains little or no myosin II (ref. 10). We find that the phagocytic cup stains strongly for F-actin (Fig. 4*e*) and myosin I (Fig. 4*g*). Myosin I occupies a zone ~1 μm wide beneath the cup (Fig. 4*g*; parentheses) and is most concentrated in a 300-nm band immediately below the plasma membrane (Fig. 4*g*; arrows).

Our data establish that, in *Dictyostelium*, myosin I is present in lamellipodia, pseudopodia and phagocytic cups, which are regions containing well developed networks of actin filaments but essentially no myosin II. By contrast, myosin II is concentrated in the posterior cortex of migrating amoebae and in the contractile ring of dividing cells, which are regions not enriched in myosin I. We cannot determine by immunofluorescence microscopy whether the myosin I in the leading edge of the *Dictyostelium* amoebae is associated with the plasma membrane or is embedded in the cortical actin network, or both, but a substantial fraction of *Acanthamoeba* myosin I is known to be tightly associated with the plasma membrane[15,16].

These observations suggest that actomyosin I-dependent force-generating activity occurs at the leading edge (as in pseudopodia extension) and that actomyosin II-dependent force-generating activity occurs at the trailing end of a migrating *Dictyostelium* amoeba (causing the cell mass to move forwards). This could explain how myosin II-minus mutants can form smaller-than-normal pseudopodia at a relatively normal rate[9]. The myosin I that is more generally distributed in the cytoplasm might be involved in other motile activities[16], perhaps with myosin II; or it might represent, at least in part, the enzymatically inactive (unphosphorylated) state of myosin I (refs 5 and 6). The conventional sliding-filament model is proably adequate to explain the contractile activity of actomyosin II, but the mechanism by which myosin I associated with the plasma membrane and F-actin could generate an extensive force is uncertain. Membrane-bound *Acanthamoeba* myosin I can generate force against actin cables however[17], and both *Acanthamoeba* and *Dictyostelium* myosin I will crosslink actin filaments and generate force between crosslinked filaments[18–21].

None of our observations is incompatible with the participation either of other processes in amoeboid movement, such as membrane flow or the remodelling of the actin matrix, or of myosin I and myosin II in other motile activities. The significance of our results is that they show the presence in the leading edge of a migrating cell of myosin I, which in conjunction with F-actin, is known to be capable of producing force and movement. □

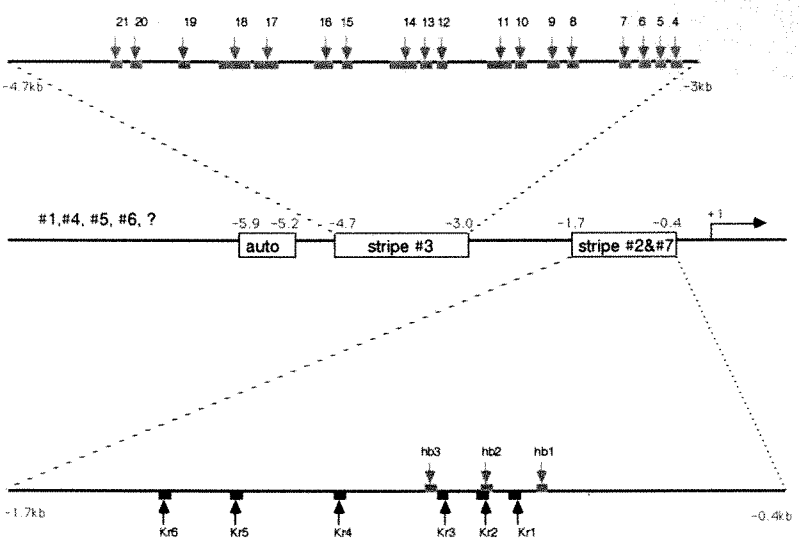
Sequence-specific DNA-binding activities of the gap proteins encoded by *hunchback* and *Krüppel* in *Drosophila*



Dusan Štanojević, Timothy Hoey* & Michael Levine

Department of Biological Sciences, Fairchild Center, Columbia University, New York, New York 10027, USA

THE segmentation of the *Drosophila* body plan depends on a hierarchy of interactions among ~20–25 regulatory genes that are active in the early embryo (refs 1–4; for a review see ref. 5). The gap genes have a key role in this process and are responsible for the periodic expression of certain pair-rule genes[6–8] and the localized expression of several homoeotic genes[9–11]. The two best characterized gap genes, *hunchback* (*hb*) and *Krüppel* (*Kr*), contain homologies with the zinc-finger DNA-binding motif[12,13], although their mode of action in the early embryo is unknown. Here we report that both of the proteins encoded by these genes possess sequence-specific DNA-binding activities, which indicates that they might regulate gene expression at the level of transcription. The binding sites of the *hb* gene product are related by a 10-base pair (bp) consensus sequence, $^{G/A}_{C/C}$ATAAAAAA, whereas the binding sites of the *Kr* gene product share a distinct 10-bp motif, AACGGGTTAA. It is possible that the *hb* and *Kr* proteins cooperatively regulate gene expression, because they are expressed in broad, overlapping gradients in the early embryo. We also provide evidence that the on/off periodicity of the pair-rule gene *even-skipped* (*eve*)[14,15] involves the interaction of the *hb* and *Kr* proteins with defined *eve* promoter elements[16,17].

We found that full-length *hb*- and *Kr*-encoded proteins produced in *Escherichia coli* are able to bind to specific sequences in the *eve* promoter. Our choice of *eve* for this analysis was based on previous genetic circuitry studies, which indicate that *eve* is an 'early' pair-rule gene that is directly regulated by the gap genes[8,17,18]. Promoter-fusion studies have identified regions

FIG. 1 Hb and Kr sites in the *eve* promoter. The central horizontal line shows the three *cis*-regulatory elements in the *eve* promoter identified. The arrow indicates the transciption start site (+1)[16,17]. The initiation of stripe 3 depends on sequences located between −4.7 and −3 kb. Truncated promoters, or promoters carrying internal deletions, that disrupt this region fail to initiate stripe 3. The initiation of stripes 2 and 7 depends on sequences located between −1.7 and −0.4 kb. Sequences located between −5.9 and −5.2 kb mediate *eve* autoregulation (Auto) during later stages of development. The regulatory sequences responsible for the initiation of stripes 1, 4, 5 and 6 were not identified in previous studies, and seem to map further upstream than −8 kb. Stripe-2 and stripe-3 elements were scanned for Hb and Kr sites by DNaseI footprint assays using overlapping DNA fragments which spanned both promoter elements. Regions protected by the *hb* protein are indicated in grey, whereas Kr sites are indicated in black. The stripe-3 promoter element (above) contains 18 Hb sites, but does not contain any high affinity Kr sites. The stripe-2 element (below) contains six Kr sites and three Hb sites. Note that each Hb site in the stripe-2 element is closely linked to a Kr site. All six Kr sites are related by a 10-bp consensus sequence shown in the bottom left column. Alignment of the Hb sites reveals a distinct consensus sequence, shown in the bottom right column. Because of lack of space, not all of the Hb sites are listed, although all contain at least one copy of the consensus sequence. Note that some of the Hb sites contain multiple copies of the consensus sequence. For example, the Hb14 site contains three copies. The boundaries of the stripe-2 and -3 elements are based on studies by Harding *et al.*[16]. An independent study was done by Goto *et al.*[17], which included an examination of *eve* promoter fusions carrying internal deletions. This study identified narrower limits for the elements essential for initiation of the two stripes. For example, Goto *et al.*[17] propose that the stripe-3 element resides between −3.8 and −3 kb, which indicates that the Hb15–Hb21 sites might not be critical for the initiation of stripe-3. Perhaps the multiple Hb sites in the stripe-3 element are functionally redundant. Alternatively, optimal expression of stripe 3 might depend on all of the Hb sites, whereas the initiation of the stripe involves just a subset of the sites. Similar arguments pertain to the stripe-2 element. Goto *et al.*[17] propose that this element maps between −1.7 and −1.1 kb, which indicates that the sites Hb1, Hb2, Kr1 and Kr2 are not essential for the initiation of stripe 2. Unfortunately, it is not clear whether stripe 2 is expressed at optimal levels when driven by *eve* promoters that lack sequences between −1.1 and −0.4 kb. Interestingly, an *eve* promoter lacking a 480-bp region in the stripe-2 element, which deletes the sites Hb3, Kr3, Kr4 and Kr5, fails to initiate stripe 2. This observation is consistent with the notion that one or more of these binding sites may be important for the expression of stripe 2. More rigorous evidence for this possibility depends on evaluating the *in vivo* expression of otherwise normal *eve*-promoter fusions carrying point mutations in the binding sites.

METHODS. Full-length *hb* and *Kr* proteins were prepared with the T7 expression vector pAR3040 (ref. 27), similar to a previously described method[28]. *In vitro* mutagenesis was done to create an *Nde*I site at the translation initiation site for each coding sequence, and each sequence was then cloned into the unique *Nde*I site of the vector. Proteins were expressed in the bacterial strain BL21(DE3), and ~15–30% of the total protein obtained after induction with IPTG corresponds to *hb* or *Kr* protein. Total induced extract was solubilized in buffer Z (ref. 28) containing 4 M urea.

in the *eve* promoter that are essential for the initiation of stripes 2, 3 and 7, and are probable targets for *hb* and *Kr* activity[16,17] (see Fig. 1).

By using DNaseI footprint assays, we systematically searched for sites able to bind the *hb* or *Kr* protein (termed Hb or Kr sites, respectively) in overlapping DNA fragments that encompassed the *eve* promoter elements essential for stripes 2 and 3 (termed the stripe-2 and stripe-3 elements, respectively). The results of such an analysis for the stripe-2 element are shown in Fig. 2. A 280-bp *Hin*fI–*Fsp*I fragment from the stripe-2 element was labelled with ^{32}P, incubated with increasing amounts of *hb* or *Kr* protein extracts, and then partially digested with DNaseI. This fragment contains three Kr sites (Kr1, Kr2 and Kr3) and three Hb sites (Hb1, Hb2 and Hb3), which represent most of the binding sites present in the stripe-2 element (Fig. 1). The proteins encoded by *hb* and *Kr* seem to recognize distinct sequences. An increase in the concentration of *hb* protein resulted in the protection of a sequence located near the labelled end of the DNA fragment (the Hb1 site; Fig. 2, lanes 5–7), which was not bound by the *Kr* protein present at any of the concentrations tested in this assay (Fig 2, lane 4). Conversely, the *Kr* protein gave strong protection of a sequence (Kr1) that was not recognized by the *hb* protein. Despite their recognition of distinct sequences, some of the Kr and Hb sites are closely linked. For example, within the resolution of DNaseI protection, the Kr2 and Hb2 sites seem to overlap, as do the Kr3 and Hb3 sites. The six Kr sites that were identified within the stripe-2 element are related by a 10-bp consensus sequence AACGGGTTAA (Fig. 1).

Systematic searches of the stripe-3 element failed to reveal any high-affinity Kr sites, although it was shown to contain nearly 20 different Hb sites. Examples of the footprint assays done with stripe-3 sequences are shown in Fig. 3. Both of the DNA fragments shown contain several regions that were protected after addition of high concentrations of *hb* protein. These regions contain at least one copy of a 10-bp consensus sequence, $^{G/A}_{C/C}$ATAAAAAA (Fig. 1). Several of the binding sites (such as Hb18) contain as many as four copies of this consensus (Fig. 3*b*, vertical arrows).

The patterns of *hb* and *Kr* expression in the early embryo indicate that the *hb* and *Kr* proteins could function cooperatively to regulate gene expression. Double-staining studies with mixtures of antibodies directed against the *hb* and *Kr* proteins showed that the two proteins are distributed in broad gradients, which overlap extensively (Fig. 4*a*). The anterior domain of *hb* expression (shown in red) overlaps with the *Kr* expression domain (shown in green). The region of the overlap stained yellow (indicated by arrows) and includes a transverse stripe of at least eight cells in width that encircles the embryo. Overlap in the *hb* and *Kr* expression patterns is observed from the time

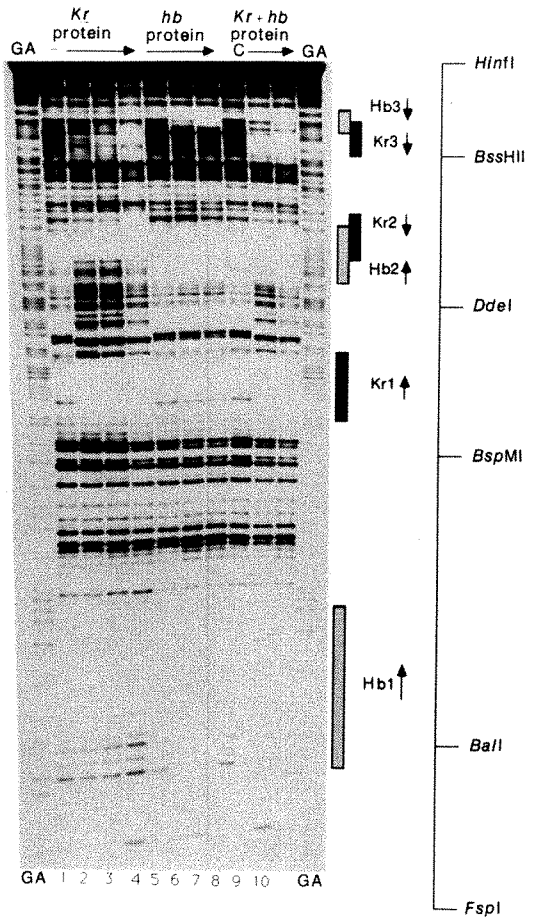

FIG. 2 Hb and Kr sites in the stripe-2 element. A 280-bp *Hin*fI–*Fsp*I fragment from the stripe-2 element was labelled with ^{32}P at the *Fsp*I site and incubated with increasing amounts of *Kr* and *hb* protein extracts. Lanes 2–4, 25, 50 and 75 μg, respectively, of *Kr*-protein extract. There are three regions that were protected from digestion with DNaseI, Kr1, Kr2 and Kr3 (black rectangles on right). Lanes 5–7, 25, 75 and 150 μg, respectively, of *hb*-protein extract. Three regions of protection are observed, Hb1, Hb2 and Hb3 (grey rectangles on right). Vertical arrows indicate orientations of consensus sequences. Lanes 9 and 10, footprint assays done with mixtures of the *hb* and *Kr* encoded protein extracts. Lane 9, 25 μg *hb*-protein extract and 25 μg *Kr*-protein extract. Lane 10, 75 μg *hb*-protein extract and 75 μg *Kr*-protein extract. Mixing experiments were done by adding both proteins simultaneously. Lane 1 (—), negative control in which DNaseI digestion of the *Hin*fI–*Fsp*I fragment was done without added protein. Lane 8 (C), control done with 75 μg protein extract from cells containing the T7 expression vector without the *hb* or *Kr* cDNA inserts. Lanes labelled GA, deoxyguanosine and deoxyadenosine sequences of the *Hin*fI–*Fsp*I DNA fragment.

METHODS. DNaseI-protection assays were carried out essentially as previously described[28,29]. Binding reactions were done with 2–5 ng ^{32}P-labelled DNA and 0.5 μg poly(dI)·poly(dC) and 0.25 μg sonicated salmon-sperm DNA in 50 μl buffer 2 for 90 min on ice. Bacterial *hb* and *Kr* proteins are extremely insoluble (particularly *hb* protein), and required the use of urea as a solvent. Urea-extracted proteins were stored at −80 °C and small aliquots were added directly to the binding reactions. Two different binding buffers were used, both providing similar results. Buffer 1: 110 mM KCl, 47.5 mM HEPES buffer, pH 7.9, 13.75 mM $MgCl_2$, 1 mM DTT, 0.1 mM $ZnCl_2$, 12% glycerol and 0.06% Nonidet P-40 detergent. Buffer 2: 100 mM KCl, 35 mM HEPES buffer, pH 7.9, 9.5 mM $MgCl_2$, 0.1 mM EGTA, 1.6 mM DTT, 0.06 mM $ZnCl_2$, 12% glycerol and 0.06% Nonidet P-40 detergent. After binding, 50 μl of 10 mM $MgCl_2$/5 mM $CaCl_2$ were added to the reaction, and then 3.5 μl freshly diluted DNaseI (Worthington) to give a final concentration of 10 μg ml^{-1}. DNaseI digestion was stopped after 2–5 min on ice by addition of 90 μl of 1% SDS, 20 mM EDTA, 200 mM KCl, and 250 μg ml^{-1} yeast transfer RNA. The samples were extracted with phenol, phenol–chloroform (1:1), chloroform, and then ethanol precipitated and electrophoresed in an 8% polyacrylamide/7.5 M urea gel.

of the initial detection of the *hb* and *Kr* proteins, and persists during gastrulation (data not shown). This overlap is far more extensive than that indicated by previous localization studies[19–21], and might have important implications for the way in which gap genes specify striped patterns of gene expression (see below). The limits of the *hb* and *Kr* expression patterns were further mapped in double-staining studies using antibodies directed against the *eve* protein. The *Kr* expression domain extends from the posterior margin of *eve* stripe 2 to the anterior margin of stripe 5 (Fig. 4*b*), whereas the anterior *hb* expression domain encompasses *eve* stripes 1 and 2 and extends into the

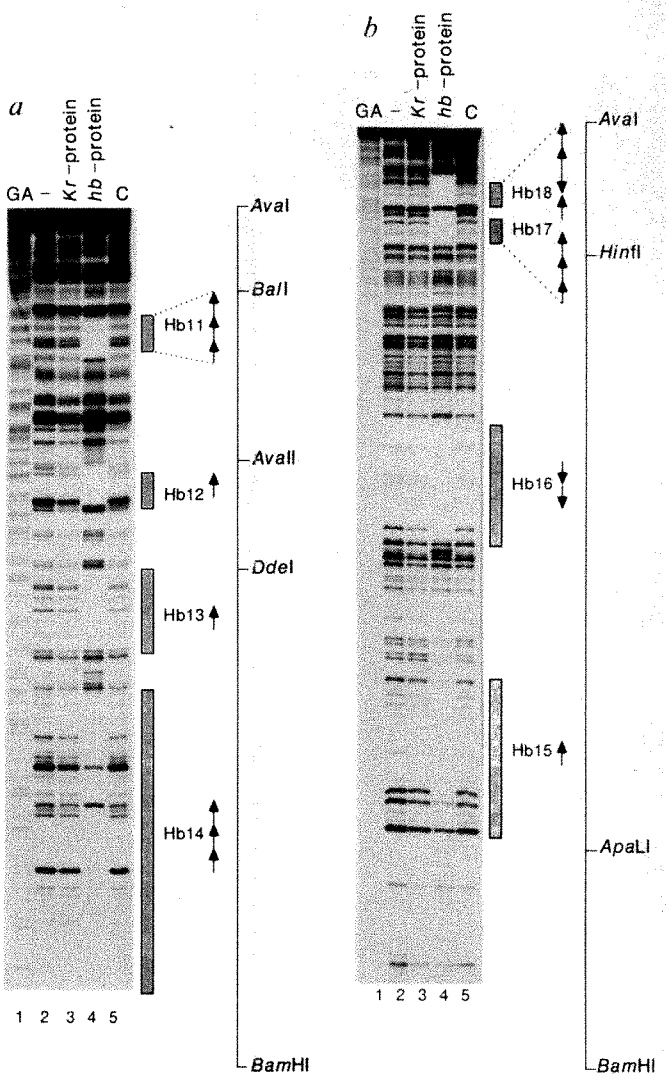

FIG. 3 Hb sites in the stripe-3 element. *a*, A 511-bp *Bam*HI–*Ava*I fragment from the stripe-3 element was ^{32}P-labelled at the *Bam*HI site and incubated with 75 μg *Kr*-protein extract (lane 3) and 75 μg *hb*-protein extract (lane 4). The *Kr* extract failed to bind any sites in this fragment. Four of the protected regions obtained with the *hb* extract are indicated by the rectangles on the right. The vertical arrows indicate the orientations of a 10-bp consensus sequence in each site (see Fig. 1). A fifth Hb site occurs near the top of the gel. Note the appearance of hypersensitive sites that flank each of the binding sites. *b*, A 583-bp *Ava*I–*Bam*HI fragment from the stripe-3 element was ^{32}P-labelled at the *Bam*HI site and used for footprint assays as described in *a*. No Kr sites are observed, but the fragment contains at least four Hb sites. One of them Hb18, contains four copies of the 10-bp consensus sequence. Lanes 2 (—) and 5 (C) in both autoradiograms are controls, as described in Fig. 2 legend. Lane 1 (GA) in each autoradiogram corresponds to the deoxyadenosine and deoxyguanosine sequences of the DNA fragment.

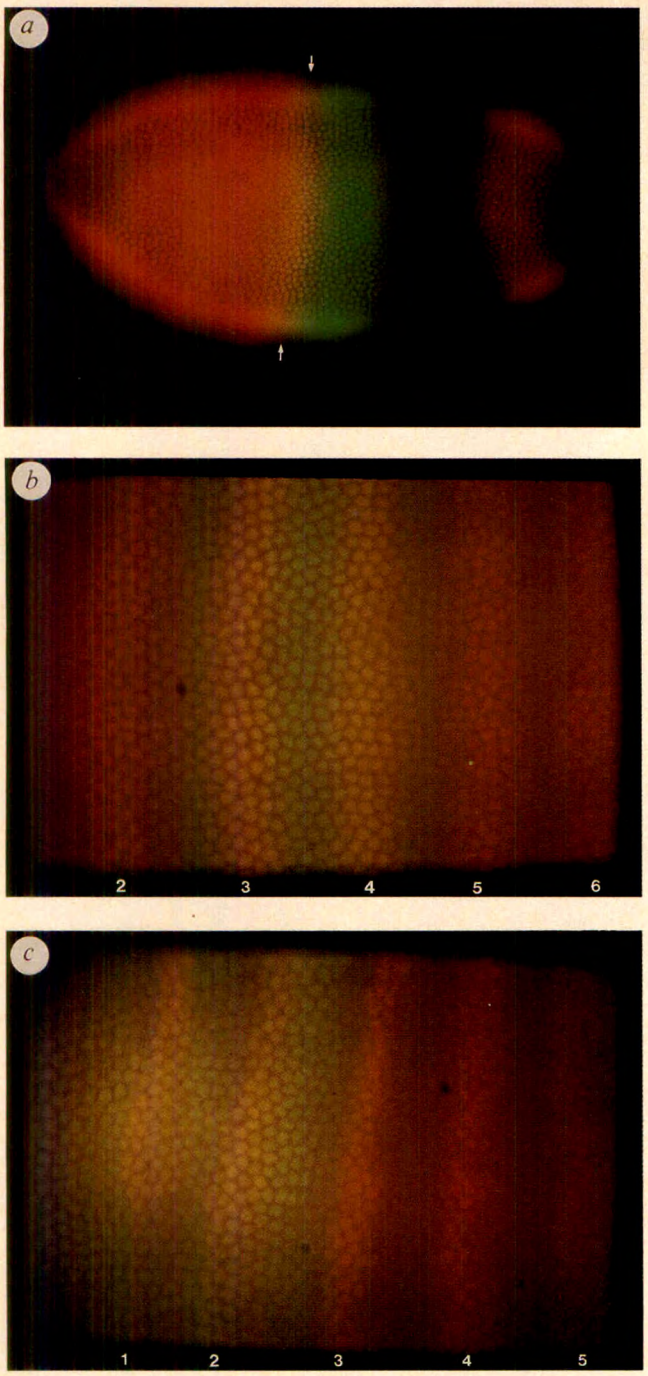

FIG. 4 Co-localization of *hb*, *Kr* and *eve* proteins in wild-type embryos. *a*, Embryo undergoing cellularization stained with a mixture of antibodies against *hb* proteins (red) and against *Kr* proteins (green). Cells that express both proteins stain yellow and are indicated by arrows. *b*, High magnification view of an embryo stained with a mixture of antibodies against *eve* proteins (red) and *Kr* proteins (green). The numbers at the bottom correspond to *eve* expression stripes 2–6. The distribution of the *Kr* protein shows a broad, bell-shaped profile, extending from the posterior margin of *eve* stripe 2 through to the anterior margin of stripe 5. *c*, High magnification view of an embryo stained with a mixture of antibodies against *eve* proteins (red) and *hb* proteins (green). Only the anterior domain of *hb* expression is observed. The protein shows a graded distribution, with more posterior regions expressing lower levels of *hb*. Expression encompasses stripes 1 and 2, and low levels of *hb* protein extend into cells expressing *eve* stripe 3. Note that stripe 3 is brighter than stripes 4 and 5, due to the appearance of both *hb* and *eve* proteins.
METHODS. Embryos were fixed and stained with antibodies as described[8]. Antibodies were: rat anti-*hb* protein, rabbit anti-*Kr* protein, and guinea-pig anti-*eve* protein. Whole sera were diluted in PBS buffer (rat, 1:200; rabbit, 1:500; guinea pig, 1:100) and preabsorbed overnight at 4 °C with fixed embryos of mixed stages. Indirect immunofluorescence was done with TRITC-conjugated anti-rat and anti-guinea pig secondary antibodies, and with an FITC-conjugated anti-rabbit antibody (Jackson Immuno Research). Photomicrographs were taken with a Nikon Optiphot fluorescence microscope. Double exposures were done by separately photographing with the fluorescein and rhodamine channels. Kodachrome daylight film (ASA 64) was used to obtain transparencies, which were printed on Cibachrome paper (Ilford).

cells that comprise stripe 3 (Fig. 4*c*). The patterns of *hb*, *Kr* and *eve* expression are summarized in Fig. 5.

Our results show that the *hb* and *Kr* proteins possess sequence-specific DNA-binding activities. Previous studies indicated such a role for these proteins, but failed to provide definitive proof[12,13,20–24]. The *Kr* protein binds with a high degree of specificity because each of the Kr sites contains a well-conserved copy of a 10-bp consensus sequence (see Fig. 1). The Kr1 site contains a 10/10 match with the consensus, and showed the highest relative affinity for the protein (data not shown). The *hb* protein seems to bind DNA cooperatively because the highest affinity sites were found to contain multiple copies of the consensus sequence of the Hb sites. Binding sites that include single copies of the consensus showed a lower affinity for the protein (data not shown).

It is probable that at least some of the Hb and Kr sites that we identified in this study play a part in mediating the complex regulatory interactions between gap genes and the *eve* promoter defined in previous genetic studies[8,17]. Goto *et al.*[17] found that a 600-bp region of the *eve* promoter (from −1.7 to −1.1 kilobases (kb)) is particularly important for the expression of stripe 2. We have shown that this region contains one Hb site (Hb3) and four Kr sites (Kr3–Kr6; see Fig. 1); a 480-bp deletion that removes these sites (except Kr6) abolishes the expression of

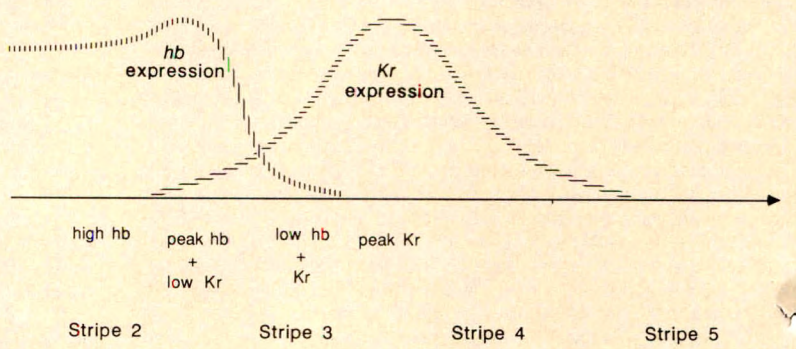

FIG. 5 *hb*, *Kr* and *eve* expression patterns. The *hb* and *Kr* proteins are expressed in broad, overlapping gradients, such that a transverse stripe of about eight cells in width expresses significant levels of both proteins. The *eve* stripes 2–5 are shown. Each *eve* stripe includes a swath of about four cells, and interstripe regions also encompass four cells. This diagram is not intended to represent the distribution of *hb* and *Kr* products in a quantitative manner, but instead simply summarizes the approximate extent of overlap among the three patterns. The *eve* stripes 2 and 3 are expressed in regions of the early embryo where there are distinctive combinations and concentrations of the *hb* and *Kr* proteins. Stripe 2 coincides with cells expressing high levels of *hb* protein, but lacking *Kr*. Stripe 3 coincides with cells expressing low levels of *hb* protein and high levels of *Kr* protein. The interstripe region separating stripes 2 and 3 contain peak levels of *hb* protein and low levels of *Kr*. The 'bulge' in *hb* protein expression at this site (parasegment 4) is due to the superimposition of *hb* products specified by both the proximal and distal *hb* promoters (after fertilization, the distal promoter is active only in parasegment 4)[30]. The periodic on/off pattern of *eve* expression could involve these different combinations and concentrations of the *hb* and *Kr* proteins.

stripe 2 (ref. 17). Similarly, removal of a 900-bp region of the stripe-3 element (from −3.8 to −2.9 kb) that contains 11 Hb sites (Hb4–Hb14) eliminates the expression of stripe 3[17]. Furthermore, we have sequenced a total of 6.4 kb of the *eve* 5′ flanking region (T.H. and M.L. unpublished results), and with very few exceptions the only sequences that share significant homologies with the consensus of the Hb and Kr sites are contained within the limits of the stripe-2- and stripe-3 elements shown in Fig. 1. DNA-binding studies support this correspondence between the occurrence of Hb- and Kr-site recognition sequences and functional regions of the *eve* promoter. For example, the most proximal 400 bp of the *eve* promoter is not essential for initiating stripes 2, 3 or 7 (refs 16, 17) and DNA-binding assays have failed to identify any *hb* or *Kr* protein binding activity in this interval (data not shown). Similarly, there do not seem to be any high-affinity binding sites in regions that map upstream of the stripe-3 element, including the distal autoregulatory element.

Perhaps the on/off periodicity of the *eve* promoter depends on distinctive concentrations and combinations of the *hb* and *Kr* proteins (for a summary see Fig. 5). Stripe 2 coincides with cells expressing high levels of *hb* protein and no *Kr* protein, whereas stripe 3 is expressed where there are low levels of *hb* protein and high levels of *Kr* protein. Genetic studies indicate that *hb* and *Kr* differentially regulate *eve* expression[8]. The *hb* gene activity exerts a positive effect on the expression of *eve* stripes 2 and 3, whereas *Kr* activity represses the expression of stripe 2. In Kr^- mutant embryos, the posterior margin of stripe 2 expands posteriorly into cells that normally contain appreciable levels of the *Kr* protein (ref. 8; R. Warrior & M.L., unpublished results; see Fig. 5). Perhaps the *hb* protein activates the expression of stripe 2 by binding to one or more of the sites in the stripe-2 element (see Fig. 1). Cells just posterior to the limit of stripe 2 seem to contain sufficient levels of the *Kr* protein, above a minimal threshold, to block activation by *hb*. Given the close linkage between the Hb- and Kr sites in the stripe-2 element, it is conceivable that the *Kr* protein blocks activation mediated by the *hb* protein by binding competitively to DNA. Alternatively, the *Kr* protein may mask (or quench) the activity of the *hb* protein through protein–protein interactions. We favour this latter mechanism, because the two proteins can occupy closely linked Hb and Kr sites; in fact it is possible that the two proteins bind to these sites cooperatively (Fig. 2; compare lane 9 with lanes 2 and 5). Similar models of protein–protein interactions have been proposed to account for the repression of *a*-specific genes in yeast by a complex of the cell-type-specific repressor $\alpha 2$ and the non-cell-type-specific protein PRTF[25], and the repression of heterologous promoters that contain multiple recognition sites for homoeodomain proteins in transient co-transfection assays[26]. □

ACKNOWLEDGEMENTS. We thank Gary Struhl and Herbert Jäckle for providing *hb* and *Kr* complementary DNA clones, and Paul Macdonald, Chris Rushlow and Rahul Warrior for providing the antibodies. D.S. is grateful to Branko Latinkic for discussions; M.L. is grateful to Gary Struhl for supporting publication of this study. The work was funded by the NIH.

The products of the *Drosophila* gap genes *hunchback* and *Krüppel* bind to the *hunchback* promoters

Jessica Treisman & Claude Desplan

Howard Hughes Medical Institute, The Rockefeller University, New York 10021, USA

THE first zygotic genes to be expressed during early *Drosophila* development are the gap genes[1–3]. Their role is to read and interpret coarse positional information deposited in the egg by the mother[4–6] and to refine it by cross-regulatory interactions[7] and by controlling a class of pair-rule genes[8,9]. Little is known about the molecular mechanisms[10] by which the three cloned gap genes[3,11,12] carry out their genetically defined functions. Here we report that the *Krüppel* (*Kr*) gene product (K_r) binds to the sequence AAGGGGTTAA, whereas the *hunchback* (*hb*) gene product (Hb) recognizes the consensus ACNCAAAAAANTA. We have identified binding sites for these proteins upstream of the two *hb* promoters, which we suggest could mediate the repression of *hb* by *Kr*[7] and perhaps allow *hb* to influence its own expression.

The presence of zinc-finger motifs[13] in both the Kr and Hb proteins[3,11] indicates that these proteins can bind to DNA. To identify fragments that contained binding sites for Kr and Hb, we used an immunoprecipitation assay based on our observation that Kr and Hb overproduced in *Escherichia coli* are insoluble but still able to bind to DNA. Such binding sites were searched for in a complex DNA mixture (the 50-kilobase (kb) bacteriophage lambda genome), which should by chance have contained sequences approaching those actually recognized by the Kr and Hb proteins *in vivo*[14–16]. We then used the protein extracts to footprint the binding sites on the precipitated fragments. Figure 1*a* presents four sequences protected by Kr and the consensus AAGGGGTTAA derived from them. A synthetic DNA fragment that contained three repeats of this sequence exhibited strong footprints with the Kr extract, but none with the Hb extract (data not shown).

We then looked for biologically relevant Kr-binding sites in the regions flanking the two *hb* promoters[3]. The proximal promoter directs early zygotic expression in the anterior part of the embryo and is dependent on the maternal gene *bicoid*[17–20]. In the absence of *Kr*, *hb* expression expands posteriorly into the *Kr*-expression domain, indicating that *Kr* normally functions to repress *hb* transcription[7]. The distal *hb* promoter is transcribed maternally[3,17] and also directs later zygotic expression in one stripe at the border between *Kr* and early *hb* expression, and in another stripe near the posterior end of the embryo[17].

The short time span of the interactions between gap genes implies that *Kr* acts directly on *hb*. We therefore searched for Kr-binding sites on a 10-kb genomic DNA fragment that contained the *hb* coding sequence and both *hb* promoters[3]. We identified two binding sites located at −676 and −359 base pairs (bp) from the proximal *hb* promoter (Fig. 1*b*); the footprint of one site is shown in Fig. 2. The sequences of the sites closely

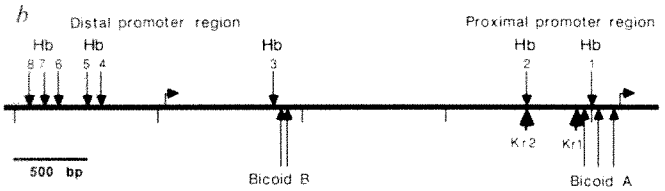

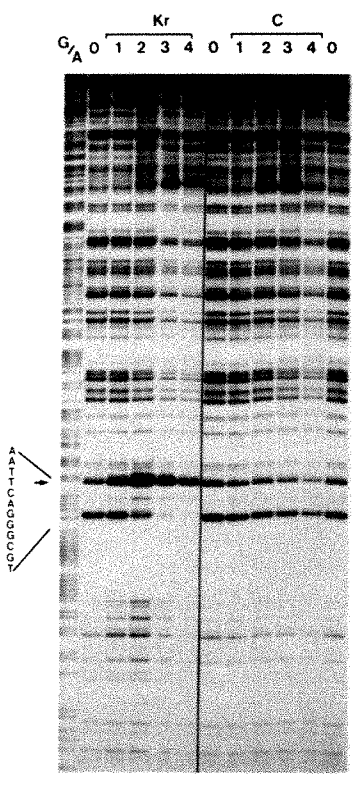

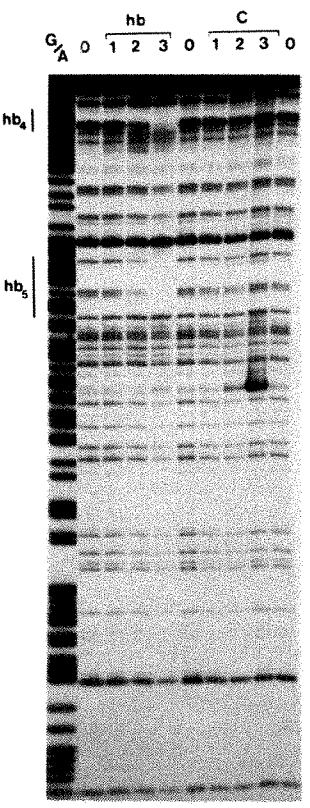

FIG. 1 *a*, Sequences recognized by the Kr and Hb proteins. Four sites in lambda DNA protected from DNase I were used to define the Kr-binding consensus sequence; Kr-binding sites upstream of the proximal *hb* promoter are also indicated. Eight sites, which are upstream of both *hb* promoters, have been footprinted by the Hb-protein extract. The protected sequences are shown together with the consensus derived from them. *b*, Summary of the binding sites detected for Kr (short vertical arrows) and Hb (long vertical arrows, above the line) in the regions of the *hb* promoters[3,17]. The positions of *bicoid*-gene-product (Bcd) binding sites, according to Driever and Nüsslein-Volhard[18] (long vertical arrows, below the line) are also shown.

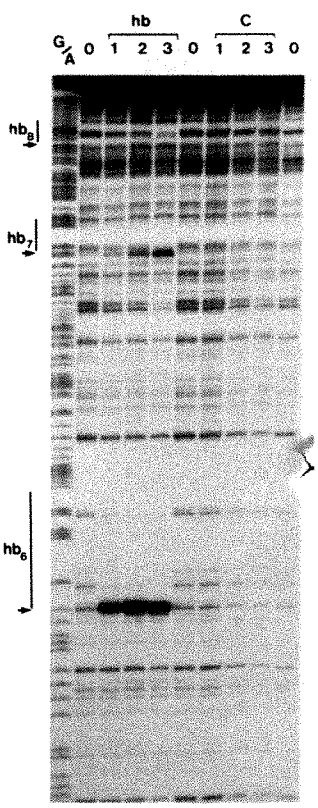

FIG. 2 DNase I footprints of binding sites for Kr and Hb flanking the *hb* promoters. G/A, Maxam and Gilbert sequencing ladder. *a*, −298 to −802-bp region of the proximal *hb* promoter, showing a Kr-binding site at −359 bp (Kr1). lanes 0, no protein extract. The other lanes contained an amount of protein extract from bacteria (containing the control pAR3040 (C lanes) or the pARKr (Kr lanes) expression plasmids) as follows (μg): lane 1, 0.2; lane 2, 1.0; lane 3, 5.0; lane 4, 25.0. *b*, −667 to −387-bp region of the distal *hb* promoter, showing Hb-binding sites at −449 bp (Hb4) and at −535 bp (Hb5). *c*, −667 to −1019-bp region of the distal *hb* promoter, showing Hb-binding sites at −731 bp (Hb6), −831 bp (Hb7) and −915 bp (Hb8). In *b* and *c* lanes 0 contained no extract. The other lanes contained an amount of bacterial extract (containing the pAR3040 (C lanes) or pARHb (Hb lanes) expression plasmids) as follows (μg): lane 1, 0.2; lane 2, 1.0; lane 3, 5.0; lane 4, 25.0.

METHODS. The pARHb plasmid was constructed by creating *Nde*I and *Bam*HI sites at the ends of a 2.4-kb genomic *Xba*I fragment[3,18] that contained the entire *hb* coding sequence[3], using amplification by the polymerase chain reaction with oligonucleotide primers that contained these sites. The resulting *Nde*I–*Bam*HI fragment was cloned into pAR3040, a T7 expression vector[24]. *E. coli* BL21 (DE3) that contained either pARKr (provided by Hoey and Levine), pARHb or pAR3040 were induced with 0.4 mM IPTG at $A_{600} \sim 0.5$, and extracts were prepared by denaturation in buffer Z containing 4M guanidine-HCl, followed by renaturation against buffer Z, according to the method of Hoey and Levine[25], except that the buffer contained no $MgCl_2$ and did contain 0.5 mM $ZnCl_2$ and 0.2 mM EDTA. The presence of zinc was not essential but did seem to result in higher activity. All labelled fragments were derived from pE8B1000, a 10-kb *Bam*HI genomic *hb* clone[3] (provided by Gaul and Jäckle). The fragment in *a* was labelled at the *Sal*I site and recut with *Hin*dIII; *b*, Fragment was labelled at the *Hin*dIII site and recut with *Hha*I; *c*, Fragment was labelled at the *Hin*dIII site and recut with *Bam*HI. DNase footprint methods: 5×10^4 c.p.m.-labelled DNA was incubated for 30 min at 0 °C in 25 μl binding buffer (20 mM Tris-HCl pH 7.5, 50 mM NaCl, 0.2 mM EDTA, 0.5 mM $ZnCl_2$, 800 μg ml^{-1} poly(dI.dC), 10% glycerol. Then 175 μl footprint dilution buffer (10 mM Tris-HCl pH 7.5, 1.2 mM $MgCl_2$, 0.25 mM $CaCl_2$, 1 mM DTT, 10 μg ml^{-1} salmon sperm DNA, 10% glycerol) was added, followed by DNase I to a final concentration of 6.25 ng ml^{-1}. After 5 min at 0 °C the reaction was stopped with EDTA and NaCl at final concentrations of 10 mM and 300 mM, respectively, and the samples were purified by phenol-chloroform extraction and ethanol precipitation before electrophoresis on an 8% sequencing gel.

match the consensus, except that they both contain a 2-bp insertion in the middle of the most highly conserved region (Fig. 1*a*). Because Kr contains four zinc fingers, relative motion between them could allow for such flexibility in the spacing of these conserved base pairs.

We are now testing short-lived *hb–lacZ* gene fusions[21] to determine whether the binding sites that we have described mediate repression of *hb* by *Kr*[7].

By using the same approach, we identified binding sites for the Hb protein that are upstream of both promoters of the *hb* gene (Fig. 1*b*). Figure 2 shows examples of DNase I footprints obtained with a crude extract that contained the Hb protein, on fragments initially identified by the precipitation assay. The consensus sequence for Hb binding is ACNCAAAAAANTA (Fig. 1*a*), which is quite distinct from the consensus bound by Kr. The central run of adenines is the most highly conserved part of the Hb-binding consensus. Repeats of the synthetic consensus sequence ACTCAAAAAACTA were protected from DNase I by Hb, but not by Kr (data not shown).

The presence of Hb-binding sites upstream of the *hb* promoters indicates that this gene could be autoregulated, as are some other developmental genes[21–23]. We are now testing the functions of these sites *in vivo*.

In conclusion, we have identified specific binding sites for the Kr and Hb proteins upstream of the *hb* promoters, through which Kr and Hb could regulate expression of *hb*. □

ACKNOWLEDGEMENTS. We thank D. Stanojevic, T. Hoey and M. Levine for discussion of their results before publication and for the pARKr clone, and U. Gaul and H. Jäckle for providing clones. S. DiNardo, S. Cohen and members of our laboratory gave us much appreciated advice and support, and P. O'Farrell's suggestions were valuable at the beginning of this work. We thank C. Fleisher for technical assistance, D. Atherton for oligonucleotide synthesis, and S. DiNardo, Y. Ohkuma, P. Gönczy, S. Dougan and M. Vashishtha for comments on the manuscript. J.T. is supported in part by the Lucille P. Markey Charitable Trust.

Krüppel requirement for *knirps* enhancement reflects overlapping gap gene activities in the *Drosophila* embryo

Michael J. Pankratz, Michael Hoch, Eveline Seifert & Herbert Jäckle

Institut für Genetik und Mikrobiologie, Maria Ward Strasse 1A, D-8000 München 19, FRG

SEGMENTAL pattern formation in *Drosophila* proceeds in a hierarchical manner whereby the embryo is stepwise divided into progressively finer regions until it reaches its final metameric form[1,2]. Maternal genes initiate this process by imparting on the egg a distinct antero-posterior polarity and by directing from the two polar centres the activities of the zygotic genes[3]. The anterior system is strictly dependent on the product of the maternal gene *bicoid* (*bcd*), without which all pattern elements in the anterior region of the embryo fail to develop[4]. The posterior system seems to lack such a morphogen. Rather, the known posterior maternal determinants simply define the boundaries within which abdominal segmentation can occur, and the process that actively generates the abdominal body pattern may be entirely due to the interactions between the zygotic genes[5–7]. The most likely candidates among the zygotic genes that could fulfil the role of initiating the posterior pattern-forming process are the gap genes, as they are the first segmentation genes to be expressed in the embryo[8–10]. Here we describe the interactions between the gap genes *Krüppel* (*Kr*), *knirps* (*kni*) and *tailless* (*tll*). We show that *kni* expression is repressed by *tll* activity, whereas it is directly enhanced by *Kr* activity. Thus, *Kr* activity is present throughout the domain of *kni* expression and forms a long-range protein gradient, which in combination with *kni* activity is required for abdominal segmentation of the embryo.

Mutations in the gap genes *Kr*, *kni* and *tll* cause large pattern-deletions in the abdomen: *Kr* affects the development of thoracic (T) and abdominal (A) segments T1 to A6 (ref. 11), *kni* affects abdominal segments A1 to A7 (ref. 12), and *tll* affects segments posterior to A7 (ref. 13). The gene *kni* is expressed in three areas at the cellular blastoderm stage[14] (Fig. 1*a*, *b*). The broad posterior domain of expression (the lack of which is most probably responsible for the gap phenotype) narrows from the posterior border during early stages of development so that the initial domain of *kni* expression pattern covers ~23–45% egg length, whereas during cellulation it spans ~30–45% (the posterior pole is 0%; for details see ref. 14). First we investigated whether the neighbouring gap genes, *Kr* and *tll*, played any part in establishing the posterior pattern of *kni* expression.

In *tll*-mutant embryos, the domain of *kni* expression is expanded towards the posterior pole (Fig. 1*c*). The simplest explanation for this is that *tll* activity represses *kni* expression, and that the lack of *tll* activity in the mutants allows *kni* to be ectopically expressed in a region where *tll* would normally be active. An unexpected result was obtained in *Kr*-mutant embryos. We did not see the anticipated expansion of the *kni* expression domain towards the anterior pole, but instead we saw a marked decrease in the level of *kni* expression in its normal posterior domain relative to that in its anterior domain (Fig. 1*d*). These observations indicate that *Kr* activity enhances *kni* expression, whereas *tll* limits the posterior border of *kni* activity by acting as a repressor.

To identify the *cis* regulatory elements of *kni* that mediate its interactions with *tll* and *Kr*, we made fusion constructs between the upstream sequences of *kni* and the bacterial *lacZ* gene (Fig. 3*a*). The constructs were integrated into the *Drosophila* germ line using P-element mediated transformation[15], and the expression pattern of β-galactosidase (β-gal) was monitored in early embryos. A construct containing ~4.4 kilobases (kb) of *kni* upstream sequence (4.4 kni–lacZ) gave the correct spatial pattern of expression in the anterior and the posterior domains (Fig. 2*a*, *b*). When this construct was placed into a *tll*-mutant background, the expression of β-gal in the posterior domain expanded towards the posterior pole, as had been observed for the endogenous *kni* expression (Fig. 2*c*). In addition, we crossed

the 4.4 kni-lacZ fusion gene construct into the background of a gain-of-function mutant for the *torso* gene[16,17]. This maternal mutation eliminates all segments in the thoracic and abdominal region and the effect is thought to be due in part to the ectopic expression of *tll* in the segmental primordia[16,17]. As shown in Fig. 2*e*, the posterior expression of β-gal is absent in these mutant embryos, consistent with the view that *tll* is a repressor of *kni* activity.

The 4.4 kni-lacZ fusion construct was then introduced into *Kr* mutants to see if the 4.4-kb fragment of *kni* also contained the *cis* regulatory elements that mediated *Kr*-dependent enhancement of *kni* expression. As shown in Fig. 2*d*, the level of β-gal expression in the posterior domain was reduced relative to the anterior domain, which served as an internal standard. This demonstrated that the *Kr*-responsive elements in *kni* resided in this 4.4-kb fragment.

We then investigated whether the *Kr*-gene product directly interacts with the *kni* upstream sequence. The 4.4-kb *kni* upstream DNA was screened for potential *Kr* protein-binding sites by immunoprecipitation[18]. Using a truncated form of bacterially produced *Kr* protein that contained the DNA-binding finger domain, we detected one DNA fragment that specifically precipitated with the *Kr* protein and antibody (Fig. 3*b*). DNase I footprinting[19] was used to characterize further the binding sites within this fragment. Two adjacent *Kr* protein-binding regions contained the sequence AAAAGGGTTAA (Fig. 3*c*).

To assess the *in vivo* relevance of these *in vitro* binding sites, we deleted the region that contained the *Kr* protein-binding sites from the 4.4 kni-lacZ construct and reintroduced the modified fragment (3.6 kni-lacZ) into flies. As shown in Fig. 2*f*, this construct gave a decreased expression of β-gal in the posterior domain relative to the anterior domain. This indicated that the sequences characterized *in vitro* are biologically important sites for the binding of the *Kr* protein. Of course, we do not know whether sites that were not detected by the footprinting but included in the deleted region also contributed to the decrease in β-gal expression. Because a low level of *kni* expression still exists in *Kr* mutants, the initial spatially restricted expression of *kni* must be dependent on factors other than *Kr*. At the moment we do not know whether a basal level of *kni* expression must be present before *Kr* can enhance the expression of *kni*, or whether *Kr* can activate *kni* transcription *de novo*. In either case, the results that we present have indicated that *Kr* activity is present and required throughout the domain of *kni* expression, and that *Kr*-gene product sets the correct level of *kni* expression by acting as a sequence-specific transcription regulator.

A long-standing dilemma has been the difference in size between the domain of *Kr* expression in wild-type embryos and the region affected in the phenotype of *Kr* mutants[20]. The pattern of *Kr* transcription revealed by *in situ* hybridization[8], as well as the initially described *Kr* protein domain[21], cover only about

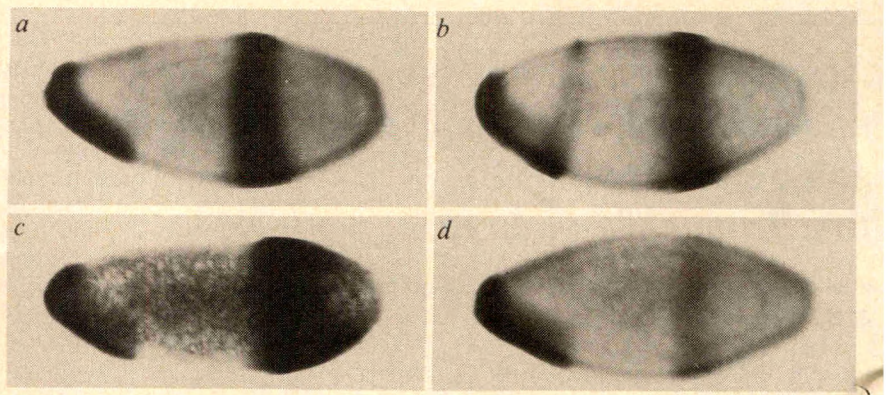

FIG. 1 Localization of *kni* transcripts by whole-mount *in situ* hybridization. Expression of *kni* in wild-type- and mutant embryos. Orientation of embryos is anterior-left and dorsal-up. *a*, Wild-type embryo at syncytial blastoderm; *b*, Wild-type embryo at cellular blastoderm; *c*, tll^{g} embryo at syncytial blastoderm; *d*, Kr^{l} embryo at syncytial blastoderm. Note the anterior and posterior domains of *kni* expression in wild-type embryos (*a*, *b*), the expansion of the posterior domain towards the posterior in the *tll* mutant (*c*), and the decrease in the posterior domain relative to the anterior in the *Kr* mutant (*d*). The *kni* complementary DNA probe pCJ15 (ref. 10) and the staining procedure of Tautz and Pfeifle[34] were used.

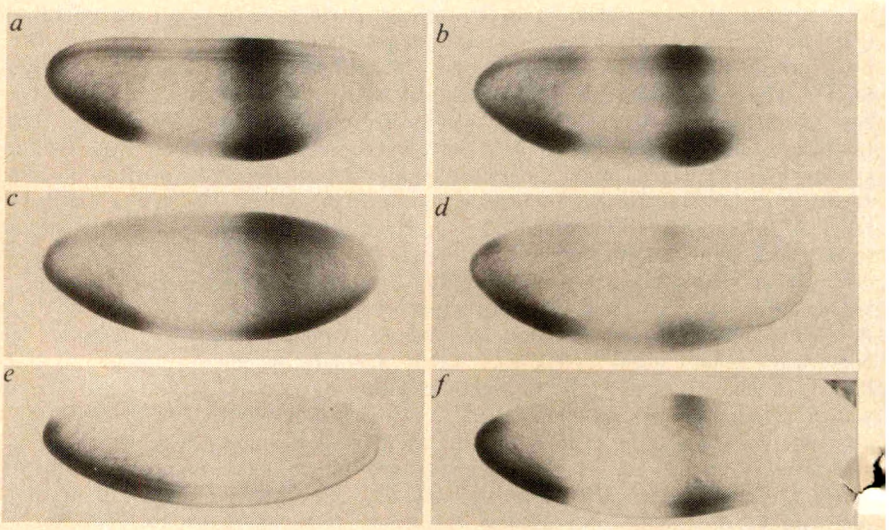

FIG. 2 Expression of β-galactosidase under the control of *kni* upstream sequences. Embryos in *a* to *e* harbour the 4.4-kb kni-lacZ construct (Fig. 3*a*). The embryo in *f* harbours the 3.6-kb kni-lacZ construct, which has the 800-base pair (bp) fragment containing the *Kr* protein-binding sites deleted (see Fig. 3). *a*, Wild-type embryo at late cellular blastoderm; *b*, Wild-type embryo at early gastrulation. Because of the stability of the RNA and/or protein, β-gal persists throughout development. Note that the relative levels of β-gal in the anterior and the posterior domains are about equal; *c*, tll^{g} embryo. The posterior domain expands towards the posterior; *d*, Kr^{l} embryo. The level of β-gal posteriorly is decreased relative to that anteriorly; *e*, tor^{4021} gain-of-function mutant embryo. The posterior domain is absent; *f*, wild-type embryo carrying the 3.6 kni-lacZ construct in which the region containing the *in vitro Kr* protein-binding sites has been deleted (see Fig. 3). Note again that the level of β-gal posteriorly is decreased relative to that anteriorly. Orientation of the embryos is anterior-left and dorsal-up. Embryos in *b* and *d* are at about the same stage of development, as are the embryos in *a*, *c*, *e* and *f*. METHODS. The appropriate *kni* DNA fragments were cloned into the P-element vector pCaSpeR AUG β-gal (ref. 35), transformed into flies[15], and the embryos harbouring the constructs assayed for β-gal expression. For each experiment, at least two independent transformant lines were tested. All embryos were stained with antibodies against β-gal as previously described[36].

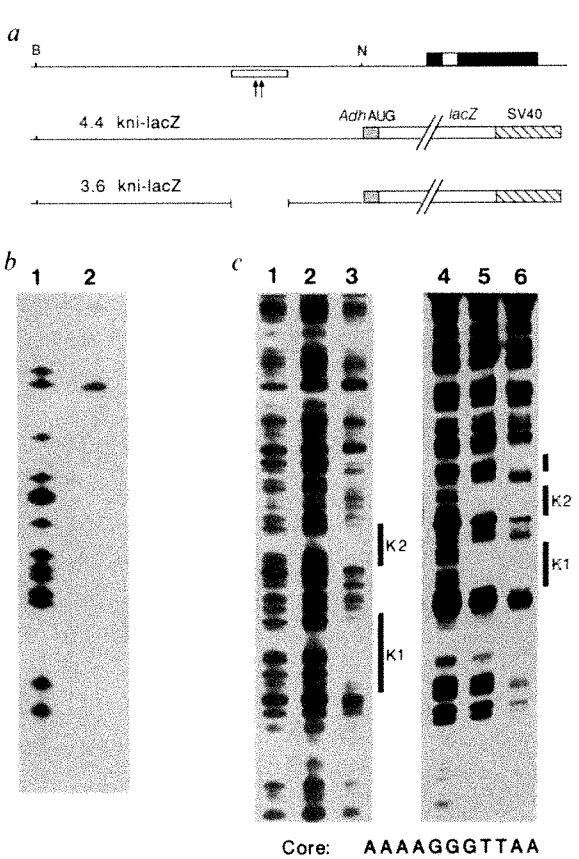

FIG. 3 Identification of *Kr*- and *tll* responsive elements in the *kni* upstream region. *a*, Top line shows the genomic map of *kni*. Black boxes are coding regions[10]. Middle line shows the fusion construct between 4.4-kb *Bam*H1(B)–*Nru*(N) upstream fragment of *kni* and the pCaSpeR AUG β-gal[35]. The bottom line shows kni-lacZ construct in which an 800-bp fragment containing the *Kr* protein-binding sites has been deleted. The unshaded rectangle below the top line indicates the fragment that specifically immunoprecipitates with *Kr* protein and antibody. The two arrows indicate the approximate positions of the sequence protected by *Kr* protein in the DNase I footprinting assay. *b*, Immunoprecipitation of *kni* upstream sequences. Lane 1 shows input DNA consisting of the 4.4-kb *kni* upstream fragment digested with *Hpa*II and end-labelled. Lane 2 shows the immunoprecipitated DNA fragment. One DNA fragment of ~800 bp specifically precipitates with extract containing *Kr* protein. No fragment precipitated with control extract made from bacteria that do not express *Kr* protein (not shown). Using a different restriction enzyme (*Taq*I), the fragment was narrowed down further to ~400 bp (not shown). This fragment was used for DNase I footprinting. *c*, DNaseI protection of *kni* upstream sequence. Left panel shows the coding strand labelled at the 3′ end. Right panel shows the non-coding strand labelled at the 5′ end. Lane 1, no protein extract. Lane 2, 1.2 μg control extract without *Kr* protein. Lane 3, 1.2 μg extract with *Kr* protein. Lane 4, no protein extract. Lane 5, 4 μg *Kr* extract. Lane 6, 16 μg *Kr* extract. The sequence protected in the coding strand is AAAAGGGTTAAACAGG for K1 and AAAAGGGTTAAG for K2. The sequence protected in the non-coding strand is AATCGCCGTATTTT-CCCAATTT for K1 and TTACGCGCGGGTATTTTCCCAATTC for K2. Therefore the common core sequence protected on both strands is AAAAGGGTTAA (reading from the coding strand). More sites become protected with increasing *Kr* protein concentration, as demonstrated by the region marked above the K2 site to the right of lane 6.

METHODS. *Kr* protein was produced in bacteria using the T7 promoter system[37]. *Kr* DNA fragment used in the expression vector started from the *Bam*H1 site located 5′ to the region encoding the DNA-binding finger motifs[38]. The extract was prepared as previously described[39]. For immunoprecipitation, crude extract was used. For DNase I footprinting, the crude extract was passed over a heparin–agarose column and eluted with KCl. The fractions were tested for the presence of *Kr* protein by western analysis and subsequently pooled. The control extract was prepared in the same way from bacteria carrying the expression vector alone without any *Kr* sequences.

half the size of the blastoderm anlagen that are affected in the mutants. It now seems, however, that these observations were limited by the degree of visual resolution, because improved staining techniques have recently allowed the detection of a much broader domain of *Kr* expression[22]. Our observation that the product of *Kr* directly binds to, and enhances the transcription of, *kni* demonstrates that *Kr* activity is not limited to the central region of the embryo. Rather, the *Kr* protein forms a steep asymmetric gradient, which extends significantly into the posterior region. Further evidence for the long-range effect of *Kr* activity is that the expression patterns of stripes five and six of the pair-rule gene *even-skipped* (*eve*), which lie outside the central high-level *Kr* domain, are altered in *Kr* mutants[23]. For the pair-rule gene *hairy* (*h*), we have identified specific DNA fragments that control the expression of individual stripes of the *h* gene. The control element responsible for the *h* stripe six contains binding sites for the *Kr* protein and requires *Kr* activity for its normal expression (M.J.P., unpublished observations). These results provide further support for the presence and requirement of *Kr* activity in the posterior region of the embryo.

If the posterior body pattern in *Drosophila* is in fact set up solely through zygotic input[5–7], then the process that generates the abdominal body pattern may be initiated by the activities of *Kr* and *kni*. Formation of the anterior body pattern requires the concentration-dependent positional information provided by the maternal morphogen *bcd* (refs 24–27); the gap genes *hunchback* (*hb*) (refs 26–29), *Kr* (ref. 30) and other possible target genes[26] respond differently to the different *bcd* protein concentrations constituting the *bcd*-protein gradient along the longitudinal axis in the early embryo[26,27]. We suggest that there could be a system analogous to that for *bcd*, but at the zygotic level, in which the *Kr*-product in combination with other gap-gene products determines positional values in the posterior segmental region. The *Kr* gene alone cannot perform this function, because in a situation where only *Kr* is expressed throughout the embryo in the absence of *hb* or *kni* expression, no segmentation is observed[30]. Furthermore, owing to the extensive overlap of gap gene activities, the relative concentrations between a given combination of gap gene products could direct diverse pattern-forming events. This would explain how so few gap genes could control a wide range of pattern-forming processes. It has already been shown for *eve* (refs 31, 32) and *h* (ref. 33) that individual pair-rule stripes possess unique identities, which are controlled by separable regulatory elements. The generation of the initial pair-rule expression patterns could, therefore, be directed by distinct positional cues that are potentially established by the overlapping gradients of the gene products of *hb* and *Kr* (ref. 22), and *Kr* and *kni*. □

ACKNOWLEDGEMENTS. We thank Steve Cöhen, Gerd Jürgens, Diethard Tautz and Detlef Weigel for helpful suggestions about the manuscript, Carl Thummel for the pCaSpeR AUG β-gal vector, Barbara Baier and Bettina Bilfi for technical assistance, and Martin Hülskamp, Mike Rothe and Detlef Weigel for performing the *in situ* hybridizations. M.J.P. thanks Detlef Weigel for his advice on fly genetics. This work was supported by the Deutsche Forschungsgemeinshaft and the Genzentrum München.

The *caudal* gene product is a direct activator of *fushi tarazu* transcription during *Drosophila* embryogenesis

Charles R. Dearolf, Joanne Topol* & Carl S. Parker

Division of Chemistry and * Division of Biology, California Institute of Technology, Pasadena, California 91125, USA

A DROSOPHILA pair-rule segmentation gene, *fushi tarazu* (*ftz*), encodes a protein which is expressed in a characteristic seven-stripe pattern[1]. The promoter sequences that are sufficient for generating this spatially restricted pattern of expression are located within 669 base pairs upstream of the transcription start site[2]. Multiple transcriptional activators and repressors interact with this 'zebra-stripe' promoter unit to bring about the positional specificity of *ftz* transcription[3]. Here we report that the homoeodomain-containing protein encoded by *caudal* (*cad*) is one such regulator. The *cad* gene product can increase the level of *ftz* transcription in the posterior half of the embryo by interacting with multiple copies of a TTTATG consensus sequence located in the zebra-stripe unit. This result demonstrates one pathway by which the product of a maternally expressed segmentation gene, expressed in an antero-posterior concentration gradient, can directly regulate the expression of a pair-rule gene.

An analysis of sequential deletions of the zebra-stripe promoter unit demonstrated that sequences between −482 and −386 base pairs (bp) from the startpoint of transcription can direct the expression of *ftz-lacZ* gene-fusion constructs preferentially in the posterior parasegments of germ-line transformed embryos (Fig. 1). The expression of β-galactosidase was observed in a continuous band rather than in discrete stripes, because the constructs did not contain the repressor elements that would normally prevent transcription in the cells that comprised the interband regions[3]. Staining was consistently seen between the parasegments that would correspond to *ftz* stripes 4–7, with stripe 7 staining most strongly. Weak staining was also detected in most embryos in the parasegments just anterior to the region corresponding to stripe 4.

The posterior-specific expression of these *ftz*-promoter fusions is similar to the pattern of expression that is observed for the *cad* protein during early embryogenesis[4,5]. Because posterior *ftz* expression is drastically reduced in *cad*$^-$ mutant embryos[4], and because the *cad*-gene product contains a homoeodomain, which indicates that the protein has a DNA-binding capability[6], we examined whether the *cad*-gene product could function as a direct regulator of *ftz* transcription. To determine if the *ftz*-promoter region responsible for posterior-specific expression contained a *cad*-protein DNA-recognition-element (CDRE), we performed DNA-binding experiments with bacterially overproduced *cad* protein. We found that this promoter fragment contains two elements that are bound *in vitro* by *cad* protein (Fig. 2*a*). Both of these elements contain two copies of a motif with the consensus TTTATG; the distal element has an inverted repeat of the motif separated by 4 bp, whereas the proximal element has a direct repeat of the sequence separated by 2 bp (Fig. 3*a*). This *cad*-protein DNA-recognition sequence is different from that reported for other *Drosophila* homoeodomain proteins (see ref. 7 for a review), which is consistent with the diverged nature of the *cad*-protein homoeodomain[6]. Additionally, at least two homoeoproteins, which recognize a TCAATTAAAT homoeodomain-binding consensus, the *even skipped* and *engrailed* proteins, do not bind *in vitro* to the TTTATG sequence (C.R.D., unpublished observations). These observations support the idea that the CDRE is specific for the *cad* protein.

Both of the elements to which the *cad* protein binds are required for the posterior expression of *ftz-lacZ* fusion constructs in germ-line transformed embryos. Point mutations in which the first and fourth base pairs of the consensus hexamer were changed to G and to T, respectively, eliminated the binding of the *cad* protein *in vitro* (Fig. 2*b,c* and Fig. 3). Mutations in either the two distal consensus sequences or in the two proximal consensus sequences also eliminated the posterior pattern of expression. The expression of β-galactosidase in embryos that were transformed with either of these mutant fusion genes resembled that of embryos transformed with gene fusions that completely lacked both the distal and proximal elements (Fig. 1). In addition to the negative effects that the mutations had on transcription, point mutations in one of the repeats seemed to reduce the level of binding of the *cad* protein at the remaining binding site ~100 bp away (Fig. 2*b,c*). This indicates that some form of cooperative binding may occur with *cad* protein. It has been suggested that homoeoproteins recognizing the TCAATTAAAT consensus sequence also bind cooperatively[8,9].

To demonstrate that *cad* protein can increase the transcription of the *ftz* gene by acting through the CDRE, we performed transient co-transfection assays in *Drosophila* Schneider-2 cells[10]. When *cad* protein was over-expressed in these cells, the increase in the transcription of a fusion construct that contained six copies of the TTTATG sequence was 12-fold more than the increase in the transcription of a construct containing six copies of a mutant hexamer (Fig. 4*a*). Furthermore, the transcription of intact *ftz*-promoter sequences which contained the CDREs was increased more than six times over that of a similar construct from which the binding sites had been deleted, and point mutations in either of the CDRE repeats reduced this transcriptional increase by 42–48% (Fig. 4*b*). This effect of CDRE point mutations on transcription differs from that found in germ-line transformants, in which mutations in either of the consensus repeat sites eliminated all detectable posterior-specific expression of the fusion constructs. This difference is probably due to the nature of the transient expression assay, in which artificially high levels of *cad* protein were present within the cell.

We suggest that *cad* protein activates *ftz* transcription in both ectodermal and mesodermal cells, even though primarily mesodermal *ftz-lacZ* expression was observed in the embryos reported here. The −6.1 to −3.4 kb upstream promoter region is necessary for full *ftz* expression in the ectoderm[2,3,11]; it is possible that these sequences are also necessary for high levels of ectodermal *cad*-driven transcription. It is also possible that *cad* protein activates *ftz-lacZ* expression in low but relatively similar amounts in both ectoderm and mesoderm, and a mesodermal enhancer element within the wild-type *rosy* gene of the Carnegie 20 injection vector may increase the mesodermal expression to readily detectable levels[12].

The work reported here demonstrates that the *ftz* promoter is activated by a regulatory factor expressed with positional specificity in the embryo, and illustrates the usefulness of

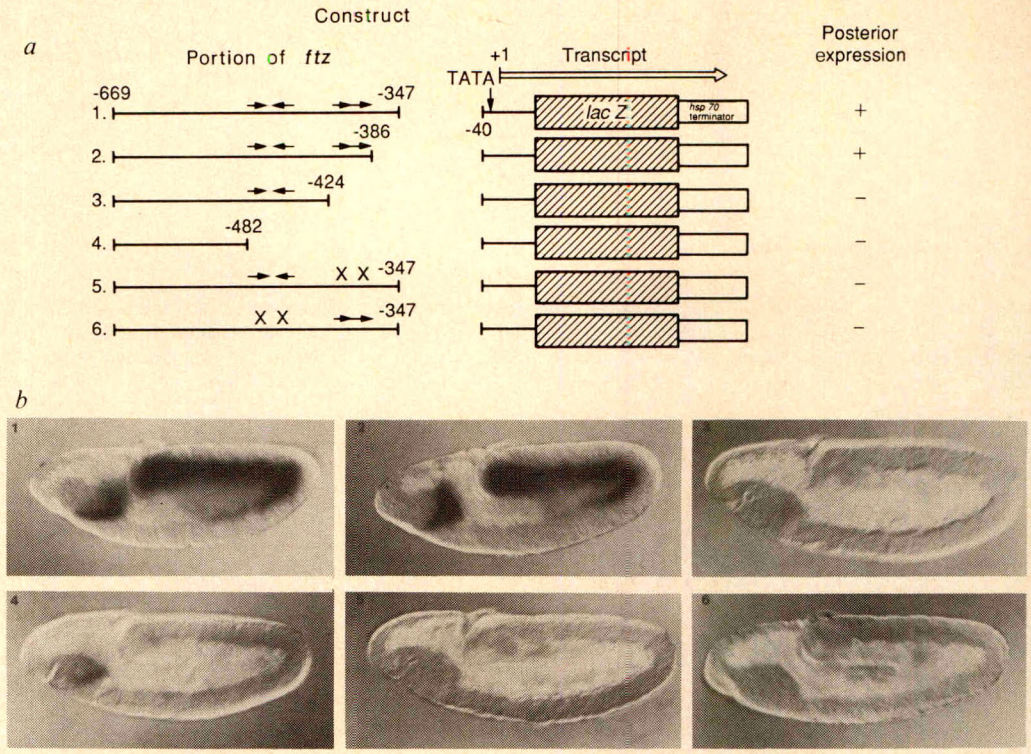

FIG. 1 Embryonic expression of germ-line-transformed *ftz–lacZ* gene-fusion constructs. *a*, Diagram of the *ftz–lacZ* portion of the constructs injected and a summary of β-galactosidaseexpression observed in the germ band of transformed embryos. Numbers given are base pairs from the start point of transcription. Each arrow represents a single copy of the CDRE, whereas each X represents a mutated CDRE to which *cad* protein does not bind. *b*, Representative transformed embryo corresponding to the constructs summarized in *a*, stainedfor β-galactosidase activity using 5-bromo-4-chloro-3-indolyl-D-galactoside (X-gal) as substrate. Because these constructs lack the *ftz* upstream enhancer element and most of the zebra-stripe element, the expression levels are greatly reduced[3]. Therefore, embryos were examined during germ-band extension, as this is the earliest stage in which β-galactosidase activity (or antigen) can be readily detected. Constructs 1 and 2, which contained two intact copies of the CDRE repeats, expressed β-galactosidase in a posterior-specific pattern (see text). Constructs 3–6, in which one or both of the CDRE repeats were deleted or mutated, did not express β-galactosidase in the germ band. The cephalic staining observed is variable and is most probably due to elements in the Carnegie 20 injection vector used in these studies[2,3,12]. METHODS. Promoter fragments of *ftz* were ligated to the 5Δ–40 construct[3], in which *ftz* sequences from −40 to +73 bp from the 5′ cap site are fused to the *Escherichia coli lac Z* coding sequences. The construction of *ftz–lacZ*-fusion genes, generation of germ-line transformants, X-gal staining of embryos, and photography were as described previously[3]. Point mutations (see Fig. 3 for base-pair alterations) were made with the Amersham oligonucleotide-directed *in vitro* mutagenesis system (version 2) according to manufacturer's instructions. At least five independent transformed lines were examined for each construct described. Embryos stained for longer periods of time than those presented show slight amounts of β-galactosidase activity in the germ band, apparently due to the presence of a general activator element located between −482 and −535 bp[3]. Constructs 1 and 4 were previously described in ref. 3 as 3′Δ–347 and 3′Δ–482, respectively.

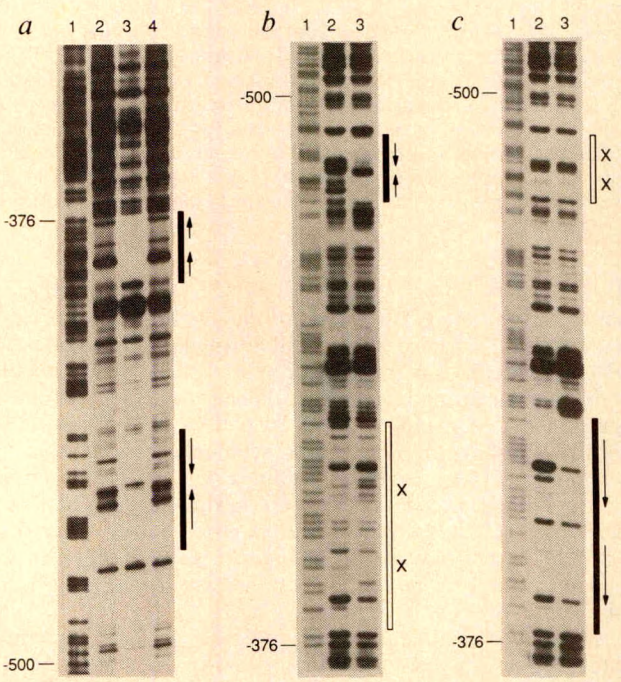

FIG. 2 DNase I protection of the *ftz* promoter by *cad* protein. Numbers given are base pairs from the startpoint of transcription. Sequences protected from DNase I digestion are indicated by solid rectangles; sequences not protected because of the generation of point mutations are indicated by open rectangles. The approximate locations of the TTTATG consensus motif are shown with arrows; locations of the mutated consensus are shown with an X. *a*, Intact fragment of the *ftz* zebra stripe promoter unit. Lane 1, T and C nucleotides; lane 2, no extract added; lane 3, extract from bacteria expressing *cad* added; lane 4, crude extract from bacteria not expressing *cad* added. Two DNase I footprint regions are seen, specific for digestion reactions in which the *cad* extract had been added. *b*, Zebra-stripe promoter fragment of *ftz* containing mutated consensus binding sites at the proximal protection region. Lane 1, T and C nucleotides; lane 2, no extract added: lane 3, *cad* extract added. *c* Zebra-stripe promoter fragment of *ftz* containing mutated consensus binding sites at the distal protection region. Lane 1, T and C nucleotides; lane 2, no extract added; lane 3, *cad* extract added. Point mutations in the TTTATG consensus motif eliminated protection from DNase I digestion around those sequences, while reducing the level of protection at the intact footprinting region. METHODS. The *cad* protein was over-expressed in BL21 (DE3) bacteria using the system of Studier and Moffatt[19]. A T7/cad vector, pcad316, was used to overproduce *cad* protein. Induction of *cad* protein and production of crude extract were performed as described by Hoey *et al.*[20], with the exception that only the supernatant from the lysate centrifugation was used for all further steps. Crude *cad*-protein extract gave reasonably strong DNase I footprints (data not shown), but to optimize footprinting activity, *cad*-protein extract was subjected to chromatography on a heparin-agarose column. The flow-through was collected and the column washed in Z buffer (100 mM KCl, 25 mM HEPES buffer pH 7.8, 12.5 mM $MgCl_2$, 1 mM DTT, 0.1% Nonidet P-40 (NP-40, 20% glycerol, and protease inhibitors phenylmethylsulphonyl fluoride (1 mM) and benzamidine (2 mM). Fractions were then step-eluted by the sequential addition of Z buffer with 200 mM NaCl, 400 mM NaCl, and finally 700 mM NaCl. The majority of *cad* protein eluted in the 400 mM NaCl fractions, as determined by anti-*cad*-protein antibodies; these fractions were pooled, dialysed against Z buffer, and frozen at −70 °C until use. Heparin agarose eluate (15 μl) was used for each footprinting reaction when required. Crude extract from bacteria not expressing *cad* protein was made from DE3 cells not transformed with pcad316, but otherwise treated in the same manner. This material (15 μl) was used for each footprinting reaction when required. DNase I digestions were performed as described previously[21], using ^{32}P-end-labelled DNA. Each reaction mix was electrophoresed on a 6% polyacrylamide gel, and the DNA fragments were detected by autoradiography.

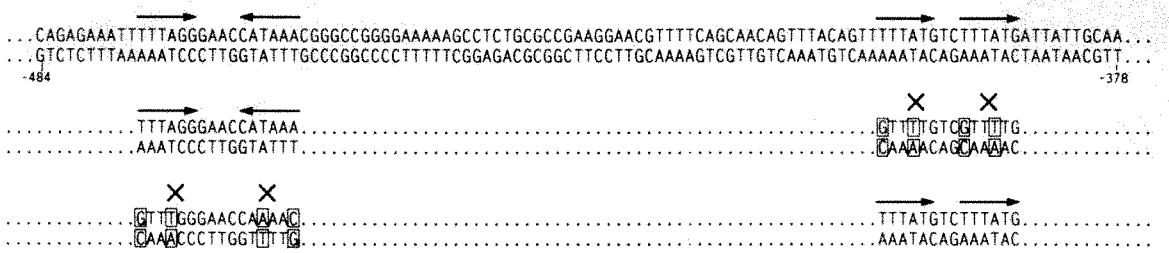

FIG. 3 Sequence of the *ftz* zebra-stripe promoter unit containing the *cad*-protein-recognition sites. *a*, Portion of the intact *ftz* promoter. Two repeats of the consensus motif are located between −474 and −388 bp from the startpoint of transcription. Three of the CDREs contain a TTTATG hexanucleotide, whereas the fourth CDRE has a TTTAGG sequence. Each copy of the motif is indicated by an arrow. *b, c*, Portion of the *ftz* promoter in which point mutations have been introduced into the proximal CDREs (*b*) or into the distal CDREs (*c*). The mutant base pairs are boxed.

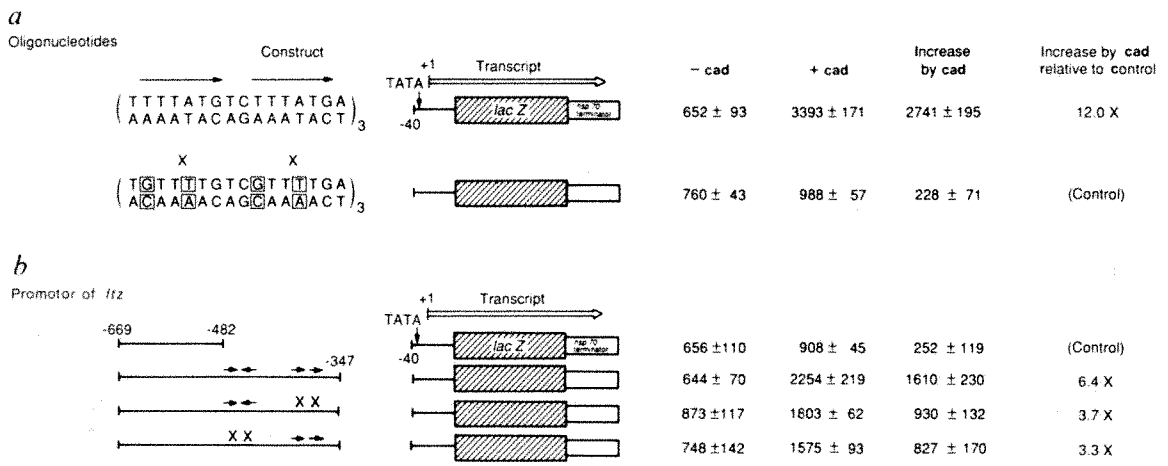

FIG. 4 Expression of CDRE fusion constructs in Schneider 2 cells overproducing *cad* protein. Fusion constructs were co-transfected with either the plasmid pP_{Ac} (ref. 10) (indicated as −cad) or the *cad* expression plasmid pP_{Ac}cad325 (indicated as +cad). The level of β-galactosidase activity in the cells was determined spectrophotometrically, and is given as arbitrary units. For each fusion construct, the increase in β-galactosidase expression due to overexpression of *cad* was determined by subtracting the activity in cells co-transfected with pP_{Ac} from that in the cells co-transfected with pP_{Ac}cad325. The calculated increases in expression levels were then compared, as indicated. *a*, Effects of *cad* over-expression on β-galactosidase activity of a fusion construct containing three copies of the proximal CDRE repeat. The control construct contains three copies of a CDRE repeat to which *cad* protein does not bind. Mutant base pairs are boxed. *b* Effects of *cad* over-expression on expression of constructs containing intact or mutated *ftz*-promoter fragments. Each intact CDRE repeat is indicated by arrows, each mutant CDRE by an X. The control construct does not contain a CDRE repeat.

METHODS. The *cad* expression vector pP_{Ac}cad325 contains the *cad* coding region and the alcohol dehydrogenase gene polyadenylation signal, inserted into pP_{Ac}, which contains the actin 5C promoter. Fusion constructs, cloned into the Carnegie 20 vector, were co-transfected with either pP_{Ac} or pP_{Ac}cad325 according to the method of Krasnow *et al.*[10], with the following alterations: 10 μg of each plasmid and 5 ml of Schneider-2 cells were used for each individual experiment. After transfection, cells were grown for 48 h at 24 °C, collected, resuspended in 270 μl assay buffer (50 mM potassium phosphate, 1 mM $MgCl_2$, pH 8.0) and frozen at −70 °C until further use. β-Galactosidase enzyme activity was determined spectrophotometrically by the method of Simon and Lis[22], using the substrate chlorophenol red-β-D-galactopyranoside. Three independent experiments were performed and the results averaged for each value obtained.

detailed promoter dissections for elucidating the complicated regulation of *Drosophila* segmentation genes; indeed, the direct interaction between the *cad* protein and the *ftz* zebra-stripe promoter unit would have been difficult to predict from a comparison of the overall expression pattern of the *cad* and *ftz* proteins. It should be noted that other more general transcription factors also seem to contribute to activating *ftz* transcription through the zebra-stripe unit, even in the posterior half of the embryo (ref. 3, and our unpublished observations). Therefore it is possible that the extreme changes in *ftz* expression in *cad*$^-$ mutant embryos[4] are due to both direct and indirect effects of the mutation.

It has been postulated that the gap genes may act as intermediates between maternal and pair-rule segmentation genes[13]. Indeed, the maternally expressed *bicoid*-gene product can activate transcription of the gap gene *hunchback*[14,15]. Furthermore, *cis*-acting elements that allow transcription in only one or a pair of stripes, and which may respond to gap gene products, have been reported for the pair-rule loci *hairy* and *even skipped*[16–18]. By contrast, the evidence so far indicates only an indirect regulation of *ftz* expression by the products of the gap genes; in addition, the data presented here demonstrate that the product of a maternally expressed gene, present in a concentration gradient along the antero-posterior axis, can interact directly with a pair-rule segmentation gene. Therefore, it seems that several types of hierarchical networks are used in the regulation of pair-rule gene transcription.

A nuclear DNA attachment element mediates elevated and position-independent gene activity

THE transcriptional activity of genes that have randomly integrated into the genomes of transfected cells and transgenic organisms is in general unpredictable, varying with the chromosomal site of the insertion[1–4]. This effect of chromosomal position on gene expression may reflect the organization of chromosomes into topologically constrained loops[5–8] and functional domains[9–12]. To assess the biological significance of these loop domains, the anchorage of DNA to the nuclear scaffold has been studied at specific gene loci[8,13–20]. We have previously defined *cis*-acting regions flanking the chicken lysozyme-gene domain that mediate the attachment of the chromatin to the nuclear scaffold. These 'A-elements' map to the 5′ and 3′ boundaries of the region of general DNase sensitivity in the active chromatin[10,17,21,22], which contains the lysozyme gene and its *cis*-regulatory elements[10,23–28]. Here we report that when a reporter gene is flanked by 5′ A-elements from the lysozyme gene, its expression in stably transfected cells is significantly elevated and is independent of chromosomal position.

For the functional analysis of the A-element attachment-region, we constructed plasmids that each contained a 'mini-domain' consisting of one of various combinations of the enhancer of the lysozyme gene lying 6.1 kilobases (kb) upstream of the start site (E)[26], the lysozyme-gene promoter (P)[26], the reporter gene (C) encoding chloramphenicol acetyltransferase (CAT), and the lysozyme-gene 5′ A-element (A), as depicted in Fig. 1. In the first series of experiments we transferred these plasmid DNAs into chicken HD11/HBCI-promacrophage cells, in which the endogenous lysozyme gene as well as the lysozyme enhancer are active[17,26], and measured the CAT activity 45 hours later (Fig. 1*b*). The results obtained with plasmids that contained either PC or EPC minidomains confirmed the previous report of stimulation by the lysozyme-gene enhancer element[26]. The transfection of cells with constructs containing A-elements at either or both ends of a PC element did not have a significant effect on the expression of CAT. In this arrangement, the A-elements remained neutral. When, however, cells were transfected with constructs in which the A-elements had been placed between the enhancer and the promoter, stimulation by the enhancer was inhibited. The constructs that contained an insertion, between the enhancer and the promoter, of a vector DNA fragment of roughly the same length as the A-element, demonstrated that only a small part (~40%) of the A-element inhibition

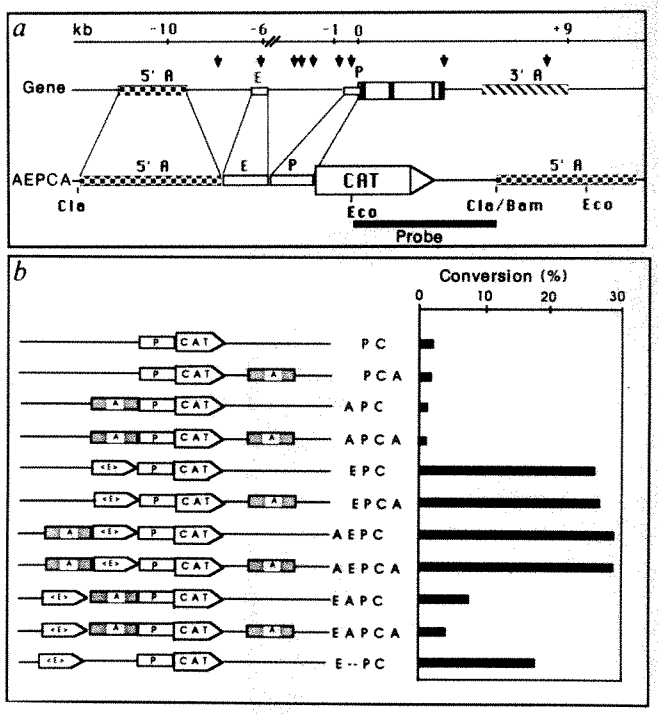

FIG. 1 Functional analysis of A-elements by their transient transfections into promacrophages. *a*, Diagram of the genomic organization of the lysozyme gene and of the construct containing an AEPCA mini-domain. In genomic location, the lysozyme domain (−12 kb to +9 kb) is flanked by 5′ (dotted box) and 3′ (hatched box) DNA attachment elements. The enhancer element[26] (nucleotides −6,331 to −5,772), the promoter element[26] (nucleotides −579 to +15) and the coding region with exons and introns (box with filled and open bars) are detailed. Arrowheads mark the positions of DNase-I-hypersensitive sites in the chromatin of various cell types[23,25]. In the construct containing the AEPCA mini-domain (not to scale), the reporter gene *CAT*, which is linked to the lysozyme-gene promoter and enhancer, is flanked by two lysozyme-gene 5′ A-elements (B1–X1 DNA fragment[17], nucleotides −11.7 to −8.7 kb). Restriction sites relevant for Southern blot analysis (for details of probe, see legend to Fig. 2) are indicated: *Cla*I (Cla), *Eco*RI (Eco), *Bam*HI (Bam). *b*, Constructs transfected into HD11/HBCI promacrophages[17,26] and CAT activity in extracts of transiently transfected cells (44–48 h after transfection[26]). Construction of plasmids containing PC (pLYSCAT2000) or EPC (pLYSCAT2100) or E--PC (pLYSCAT2300) was as described previously[26]; plasmids containing the minidomains PCA, APC, APCA, EPCA, AEPC or AEPCA were constructed by blunt-end ligation of the lysozyme-gene 5′ A-element into the *Xba*I and/or the *Bam*HI site of plasmids containing PC or EPC. Plasmids containing EAPC or EAPCA were constructed by subcloning the enhancer fragment *Bam*HI–*Sau*3A[26] into the *Bam*HI site of the plasmid pB-1–X1[17], reisolation of a fragment containing the 5′ A-element and the enhancer, and recloning by blunt-end ligation into the *Xba*I site of plasmids containing PC or PCA.
METHODS. HD11/HBCI cell growth, transfection and CAT assays were performed as described[26]. CAT activity is given as the percentage of chloramphenicol acetylated by 10 μl of cell extract incubated for 1 h at 37 °C. Values are averages of three independent transfection experiments.

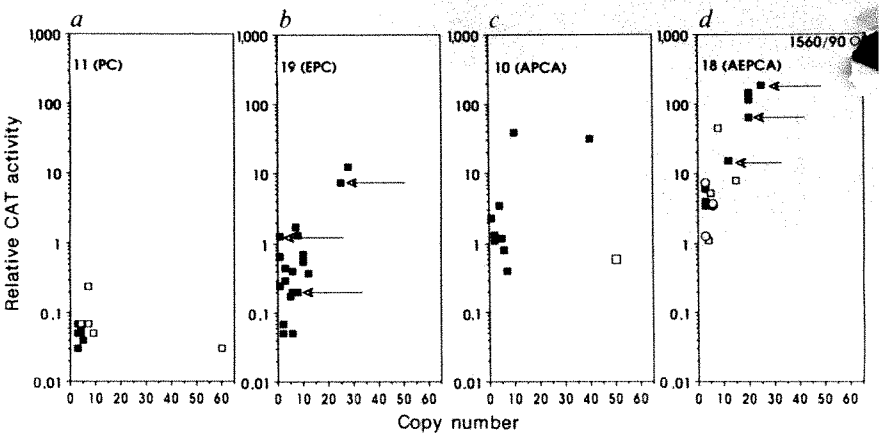

FIG. 2 Effect of A-elements on the activity of stably integrated reporter genes. Each dot represents 1 of 58 stably transfected HD11/HBCI cell clones of two independent series of experiments (open and closed symbols). Copy number of correctly inserted DNA is plotted versus relative CAT activity. *a*, 11 clones with inserted PC-containing plasmid DNA; *b*, 19 clones of EPC-containing cells; *c*, 10 clones of APCA-containing cells; *d*, 18 clones of AEPCA-containing cells. Control experiments demonstrated that A-elements in integrated constructs containing AEPCA retained the ability to attach to the nuclear matrix or scaffold obtained from lithium 3',5'-diiodosalicylate-extracted nuclei (L. Phi-Van, unpublished results). In AEPCA-containing cells, represented by circles, the upstream A-element is in sense orientation; those cells represented by squares have the A-element in the antisense orientation. Arrows mark cell clones used for Fig. 3. The AEPCA cell clone (represented by an open circle in the right upper corner of Fig. 2*d*) has the true values of relative CAT activity 1560 and the copy number 90, as indicated.

METHODS. DNA transfection was as described[26]. Plasmid (2 μg) containing the neomycin-resistance gene[29] linked to the long terminal repeat promoter of the murine-leukaemia-virus and the poly(A) signal of the thymidine kinase (*tk*) gene of the herpes simplex virus (pMPIneo), and 48 μg of the different CAT plasmid constructs were cotransfected into 2×10^6 promacrophages. 72 h later, cells were harvested, diluted (1:3) with medium containing 500 μg ml^{-1} G418 antibiotic. After 4 weeks, G418-resistant clones were isolated. Integration of transfected DNA was analysed by Southern blotting of 10 μg genomic DNA (*Bam*HI digestion of PC- and EPC-containing cell DNA, *Cla*I digestion of APCA- and AEPCA-containing cell DNA and hybridization with probe shown in Fig. 1*a*). On average, 50% of clones showed correct integration; clones with incorrectly integrated DNA were discarded. Copy numbers of integrated DNA were determined by quantitative Southern blotting. DNA of clones with correctly integrated DNA was digested with *Eco*RI and hybridized with the probe shown in Fig. 1*a*. Signal intensities were compared with standards derived from dilution series of plasmid DNA (not shown). CAT activity was determined as described[26]. 1 unit of relative CAT activity represents the conversion of 1% chloramphenicol by incubation with 300 μg extract protein for 1 h at 37 °C (86.6 pmol acetylated chloramphenicol per mg of protein per hour).

could be accounted for by the increased distance between the enhancer and the promoter.

To study the function of A-elements when they are stably integrated into the genome, we co-transfected selected plasmid DNA-constructs together with plasmids carrying a neomycin-resistance gene[29] into HD11/HBCI cells, and isolated promacrophage cell lines that were clonally derived and neomycin resistant; each of these clones represents an individual integration event. Figure 2 summarizes the result of an analysis of 58 cell lines, in which the transfected DNA-constructs were correctly integrated into the genome (Southern blots not shown). The relative CAT activity has been plotted versus the copy number of the integrated plasmid DNAs, as determined by quantitative Southern blots. The panels demonstrate the clonal distribution of genomic insertion events with PC-, EPC-, APCA- and AEPCA DNA (Fig. 2*a*–*d*). The comparison of CAT activities produced by the two constructs that lacked A-elements clearly demonstrates that the enhancer has an average stimulatory effect when it is in a genomic location. It compares well with the results of transient transfection assays (Fig. 1*b* and ref. 26). The CAT activities of individual enhancer-activated cell lines, however, differed considerably (Fig. 2*b*). This variability exemplifies the commonly observed copy-number independence that results from the genomic position effect.

The presence of A-elements at both ends of the inserted DNA dramatically affected the activity of the reporter gene in two ways. First, comparisons of the CAT activity of PC-containing cells with that of APCA-containing cells (Fig. 2*a*, *c*) and of the CAT activity of EPC-containing cells with that of AEPCA-containing cells (Fig. 2*b*, *d*), show that there was significant A-element-dependent stimulation of the reporter-gene activity. Second, consistently high-level CAT activity that was dependent on the copy number was obtained in AEPCA-containing cells (Fig. 2*d*), in which the inserted DNA elements resembled the arrangement of the endogenous domain of the lysozyme gene. A-elements seemed to buffer the inserted mini-domain from the influence of nearby genomic regions. Both of the A-element activities—the stimulatory activity as well as the activity that produced independence of the integration site—were found, irrespective of the orientation of the upstream A-element (Fig.

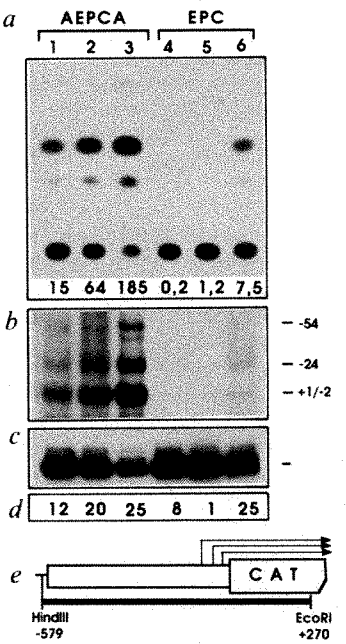

FIG. 3 A-elements stimulate transcription start at the correct promoter site. *a*, CAT assays of six AEPCA- and EPC-containing cell clones (indicated by arrows in Fig. 2). *b*, S1-nuclease mapping analysis of *CAT*-gene transcripts in total cellular RNA. Numbers indicate positions of start sites with respect to the main start site of the lysozyme-gene promoter[26,30]. *c*, Signals of S1-nuclease mapping analysis of endogenous β-actin-specific transcripts. *d*, Copy number of inserted AEPCA- and EPC-containing constructs (see Fig. 2). *e*, Schematic diagram showing S1-nuclease mapping of *CAT*-gene transcripts. Total cellular RNA was hybridized to a 849-bp *Hin*dIII–*Eco*RI fragment of PC-containing plasmid (pLYSCAT2000; ref. 26) labelled at the *Eco*RI site. METHODS. CAT activity was determined as described in Fig. 2. Preparation of RNA and S1-nuclease mapping analysis were performed as described[26] with the following modifications: for the analysis of *CAT*-gene-specific transcripts, 100 μg RNA was hybridized to the DNA probe for 12 h at 43 °C; for β-actin-specific transcripts, 5 μg RNA was hybridized for 12 h at 50 °C. After hybridization the samples were digested with S1 nuclease (250 units) at 37 °C for 1 h.

2*d*). Figure 3 demonstrates that, also, A-elements in genomic position stimulate the start of transcription from the correct promoter site, an effect that has previously been shown for the lysozyme-gene enhancer in transiently transfected promacrophages[26]. The signals from the quantitative S1-nuclease mapping of the reporter gene transcripts in three AEPCA-containing and three EPC-containing cell lines show that the level of transcripts parallels the activity of the reporter enzyme (Fig. 3*a*, *b*, *e*). The 5′ ends of the reporter-gene transcripts were characteristic of the multiple messenger RNAs generated from the chicken lysozyme promoter[26,30].

Transcriptional stimulation of the A-elements added to the stimulatory activity of the enhancer (Fig. 2), yet A-elements and the enhancer stimulated in a functionally distinguishable manner. A-element activity can only be monitored when the element is stably integrated into the genome. In addition, the 5′ A-element of the lysozyme gene does not coincide with a classical DNase-I-hypersensitive site in chromatin[17,23]. Position independence was also found recently for inserted DNA constructs containing the human β-globin gene domain[11,12] and was attributed to the presence of a far-upstream DNA site called the dominant control region. Here we have shown that high-level activity of the reporter gene that is independent of the position of insertion demands two types of elements—the enhancer lying 6.1 kb upstream of the lysozyme gene, and the 5′ A-element of the lysozyme locus.

The two activities of the 5′ A-element of the lysozyme gene in (1) sequestering functional chromatin domains and (2) increasing transcriptional efficiency, may both be functions of the structural features of the A-element that have been described previously: A-elements can attach to nuclear scaffold material and they also carry sequence motifs that are similar to the consensus sequences of DNA topoisomerase II (ref. 17). The molecular mechanism of the function of A-elements must ultimately also explain the more-than-linear (cooperative) enhancement of transcriptional activity with increasing copy number of clustered reporter genes which we observed (Fig. 2*d*). Whatever this mechanism, the 5′ A-element of the chicken lysozyme gene may be only the first example of a new type of *cis*-acting DNA element which is very useful for increasing transcriptional activity and ensuring the correct control of randomly inserted transgenes. □

A membrane-targeting signal in the amino terminus of the neuronal protein GAP-43

Mauricio X. Zuber, Stephen M. Strittmatter & Mark C. Fishman

Developmental Biology Laboratory of the Massachusetts General Hospital Cancer Center, Departments of Medicine and Neurology of Harvard Medical School, and the Howard Hughes Medical Institute, Wellman 4, Massachusetts General Hospital, Boston, Massachusetts 02114, USA

NEURONS and other cells, such as those of epithelia, accumulate particular proteins in spatially discrete domains of the plasma membrane. This enrichment is probably important for localization of function, but it is not clear how it is accomplished. One proposal for epithelial cells is that proteins contain targeting signals which guide preferential accumulation in basal or apical membranes[1]. The growth-cone membrane of a neuron serves as a specialized transduction system, which helps to convert cues from its environment into regulated growth. Because it can be physically separated from the cell soma, it has been possible to show that the growth-cone membrane contains a restricted set of total cellular proteins[2], although, to our knowledge, no proteins are limited to that structure. One of the most prominent proteins in the growth-cone membrane is GAP-43 (refs 3–5; for reviews see refs 6 and 7). Basi *et al.* have suggested that the N-terminus of GAP-43 might be important for the binding of GAP-43 to the growth-cone membrane[8]. Skene and Virag[9] recently found that the cysteines in the N-terminus are fatty-acylated and that this post-translational

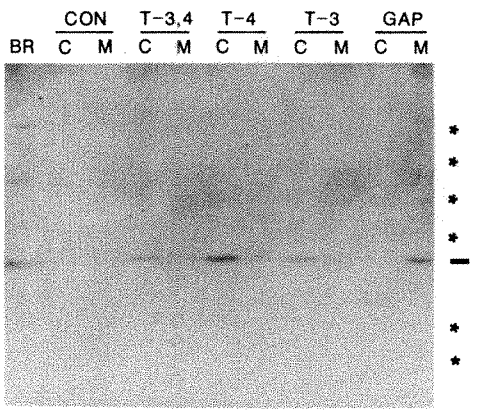

FIG. 1 GAP-43 N-terminal mutations prevent membrane association. COS cells were transfected with the expression vector pGAP (GAP) or with plasmids containing point mutations (Cys to Thr) at position 3 (T-3), position 4 (T-4) or position 3 and 4 (T-3,4). Immunoblots of membrane (M)- and cytosolic (C) fractions stained with anti-GAP antibody show that GAP-43 immunoreactivity co-migrated with purified GAP-43 protein (bar on right) and was greatly enriched in the membrane fraction. By contrast, the mutant GAP proteins were all more concentrated in the cytosol. Non-specific staining by the antibody was negligible in control fractions from CDM8-transfected COS cells (CON). A crude membrane fraction from rat brain (BR) shows immunostaining at a band corresponding to the same relative molecular mass (M_r) as the band for the GAP-transfected COS cells. The migration positions of protein standards with M_rs of 116,000 (116K), 84K, 58K, 48.5K, 36.5K and 26.6K are indicated by the asterisks.
METHODS. Point mutations in GAP-43 were generated from single-stranded DNA made from pGAP and used to alter the cysteines to threonines. The oligonucleotides GGCATGCTGACCTGTATG, ATGCTGTGCACTATGAGA, and GCAGGCATGCTGACCACTATGAGAAGAACC were used to mutate Cys 3 to Thr, Cys 4 to Thr, and Cys 3, 4 to Thr respectively. After mutagenesis, a 200-base pair (bp) fragment containing the mutation was subcloned into a non-mutated plasmid. The sequence was confirmed after mutagenesis by dideoxy chain-termination sequencing. Other procedures are as described in Fig. 2.

modification correlates with membrane-binding ability. We investigated the binding of GAP-43 to the growth-cone membrane by mutational analysis and by laser-scanning confocal microscopy of fusion proteins that included regions of GAP-43 and chloramphenicol acetyltransferase (CAT). We found that a short stretch of the GAP-43 N-terminus suffices to direct accumulation in growth-cone membranes, especially in the filopodia. This supports a previous proposal[8,9] for the importance of this region of GAP-43 in determining the membrane distribution of GAP-43.

Although GAP-43 lacks the hydrophobic amino-acid sequences that are characteristic of integral membrane proteins[9,10], it resists dissociation by agents that usually remove peripheral membrane proteins[9,11-14]. Hence, the mechanism of membrane binding is not clear. We have found that transfected GAP-43 binds to the membrane in COS cells and other non-neuronal cells[15]. The high level of GAP-43 expression in COS cells permitted preliminary screening to determine which regions were important in membrane association. Whereas membrane binding persists after deletion of a large internal segment (residues 41–189 out of 226 residues), or after deletion of the C-terminal eight amino acids and substitution of an unrelated dodecapeptide, the deletion of amino acids 2–5 markedly diminishes membrane binding (data not shown). Contained in the N-terminus are the only two cysteines in GAP-43, at positions 3 and 4, and it seemed reasonable that this unusual structure of adjacent sulphydryl groups might contribute to membrane binding. As shown in Fig. 1, in which cytosolic and membrane cell-fractions are compared, GAP-43 binds predominantly to the membranes, whereas replacement of Cys 3 or Cys 4, or both, by threonine, causes most of the protein to remain cytosolic. These two cysteines are palmitylated and this correlates with membrane association in brain[14]. Thus, the N-terminus of GAP-43, especially its N-terminal cysteine residues, seem to be necessary for the binding of GAP-43 to membranes.

To determine whether the N-terminus is sufficient to confer on GAP-43 the ability to bind to membranes, we made constructs that encoded differing amounts of the GAP-43 N-terminus fused to a reporter peptide, and expressed them in COS and PC12 cells. We chose chloramphenicol acetyltransferase (CAT) as the reporter peptide because it is cytosolic when expressed in eukaryotic cells and is very stable. We constructed plasmids that encode fusion proteins containing either the first 10 amino acids of GAP-43, Met-Leu-Cys-Cys-Met-Arg-Arg-Thr-Lys-Gln, fused to the N-terminus of the complete CAT protein ($GAP_{10}CAT$), or the first 40 amino acids of GAP-43 fused to CAT ($GAP_{40}CAT$). As shown by immunoblotting, the CAT that was expressed in COS cells (Fig. 2*a*) or PC12 cells (Fig. 2*b*) was present only in the cytosolic fraction. By contrast, the chimaeric proteins $GAP_{10}CAT$ and $GAP_{40}CAT$ were membrane-associated. We were able to extract the fusion protein with detergent,

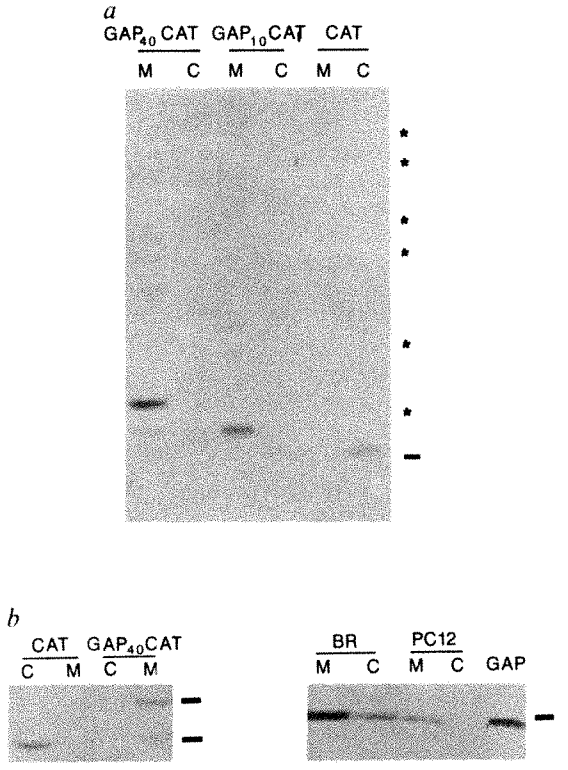

FIG. 2 Membrane association of GAP-43 and GAP-CAT fusion proteins. *a*, Chimaeric proteins with the N-terminus of GAP-43 fused to CAT associate with COS cell membranes. The constructs CAT, $GAP_{10}CAT$ and $GAP_{40}CAT$ were transiently expressed in COS cells. Immunoblots of membrane (M)- and cytosolic (C) fractions from each transfection were prepared using anti-CAT antibody. Note that in the CAT-transfected cells, immunoreactivity was found only in the cytosolic fraction and co-migrated with purified CAT protein (indicated by the bar). In the $GAP_{40}CAT$- and $GAP_{10}CAT$-transfected cells, nearly all of the immunoreactivity was membrane-associated and migrated more slowly than that for CAT-transfected cells, as expected for fusion proteins with an M_r of 4K or 10K greater than CAT. Protein standards with M_rs of 116K, 84K, 58K, 48.5K, 36.5K and 26.6K migrated as indicated by the asterisks. *b*, Membrane association of GAP and $GAP_{40}CAT$ in PC12 cells. Stably transfected PC12 cells expressing CAT, $GAP_{40}CAT$ or GAP were selected as described below. Immunoblots of membrane (M)- and cytosolic (C) fractions were stained with anti-CAT antibodies (left panel) or anti-GAP (right panel) antibodies. CAT-transfected cells (CAT) contained immunoreactivity in the cytosolic, but not in the membrane fraction, and this immunoreactive CAT co-migrated with purified CAT (lower bar to right of left panel). In contrast, $GAP_{40}CAT$ transfected cells contained membrane-associated CAT immunoreactivity, which migrated more slowly (upper bar). Fractions from rat brain (BR) demonstrate that most, but not all, endogenous GAP-43 immunoreactivity was membrane-associated. In transfected PC12 cells over-expressing GAP-43 (PC12), nearly all of the GAP-immunoreactivity was membrane-associated and co-migrated with purified GAP-43 (GAP; indicated by far-right bar).

METHODS. In the GAP-43-expression plasmid, pGAP, the GAP-43-coding sequence replaced the stuffer region at the *Xba*I sites of the CDM8 plasmid described by Seed[25]. The inserted GAP-43 sequence included the entire coding sequence of rat GAP-43, from the *Nla*III site at the start of translation to the *Sau*3AI site 68 bp downstream from the termination codon[8]. For the CAT expression plasmid, pCAT, the *Hin*dIII–*Bam*HI fragment containing the CAT-coding sequence and polyadenylation site from pSV2CAT[26] replaced the *Hin*dIII–*Bam*HI fragment of CDM8 containing the stuffer region and polyadenylation site. Plasmids $pGAP_{40}CAT$ and $pGAP_{10}CAT$ included sequences encoding the first 40 or 10 amino acids of GAP-43, respectively, fused in-frame with *CAT* in pCAT by the use of polylinkers. For transient transfection of COS cells we used DEAE-dextran and chloroquine as described[27]. For stable transfection of PC12 cells we used a neomycin-resistance plasmid co-transfected with the plasmid of interest on a 1:10 ratio as described[15]. During selection of PC12 cells, 400 $\mu g\ ml^{-1}$ of active Geneticin (GIBCO) were used. Transient transfection of PC12 cells was by electroporation with the BioRad electroporation system using 300 V and 960 μF. After 8 h the medium was changed. Twenty-four hours after electroporation the cells were plated on poly-D-lysine-coated coverslips in the presence of 50 ng ml^{-1} NGF and analysed 24 h later. For immunochemical assays, rabbit anti-GAP-43 antibodies were made by immunizing rabbits against four peptides including amino-acid residues 1–24, 35–53, 53–69, and 212–228 of rat GAP-43. Anti-GAP-43 antibody was affinity-purified on GAP peptide agarose. Anti-GAP antibody was bound to a resin which contained 10 mg ml^{-1} of each peptide coupled to agarose by the cyanogen bromide method, and the antibody was eluted at pH 3.5. Rabbit anti-CAT antibodies were obtained from 5 Prime-3 Prime Inc. Secondary antibodies were obtained from Organon Teknika, Jackson Immunologicals and Vector Labs. For cell fractionation, COS or PC12 cells were scraped from 100-mm confluent Petri dishes and pelleted at 2,000*g* for 10 min. The pelleted cells were homogenized by Polytron in 10 mM Tris- HCl, 1 mM EDTA, pH 7.6 (300 μl per dish) and centrifuged at 250,000*g* for 30 min at 4 °C. The supernatant was collected as the cytosolic fraction. The pellet was washed by homogenization and centrifugation in the same buffer, and then resuspended to the same volume as the cytosol fraction. Rat brain was obtained from 3-day-old rats and homogenized by Polytron in 10 mM Tris-HCl, 1 mM EDTA, pH 7.6 (10 ml per gram of wet-weight tissue). The cytosolic and washed-membrane fractions were prepared by centrifugation as described for the cell extracts. GAP-43 protein was purified from rat brain by a modification of the method of Andreasen *et al.*[28] and used as a positive control for immunostaining. The same volume of cytosolic or membrane fraction (usually 100 μl) was electrophoresed on polyacrylamide gels[29]. Proteins were electrophoretically transferred to nitrocellulose and excess sites were blocked with 4% BSA. Membranes were then incubated for 24 h at 4 °C with 40 $\mu g\ ml^{-1}$ affinity-purified anti-GAP, or a 1:1,000 dilution of anti-CAT antibodies. Bound antibody was detected using anti-rabbit horseradish-peroxidase method (Vectastain) according to the manufacturer's instructions. Tetramethyl benzidine (Kirkegaard and Perry, Gaithersburg, Maryland) was used as peroxidase substrate.

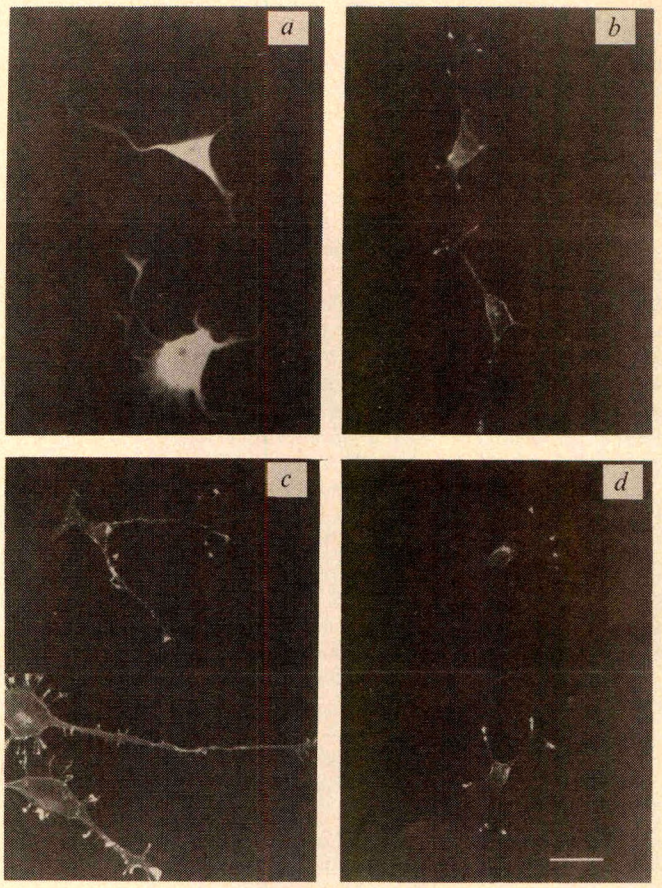

FIG. 3 Subcellular localization of CAT, GAP-43 and fusion proteins in transfected PC12 cells. Confocal immunofluorescence of CAT (*a*), GAP-43 (*b*), $GAP_{40}CAT$ (*c*), and $GAP_{10}CAT$ (*d*) in PC12 cells. Two representative fields of cells transfected with each plasmid are shown. CAT labelling is diffuse and cytosolic, whereas GAP-43 is localized to the membrane in a punctate fashion with some enrichment in the growth cones. When either the N-terminal 40 amino acids ($GAP_{40}CAT$) or 10 amino acids ($GAP_{10}CAT$) were fused to CAT, the immunofluorescent distribution resembled that for GAP-43, including enrichment in growth cones. All cells were treated with NGF for 24 h before fixation. Anti-CAT antibody was used for *a*, *c*, and *d*, whereas anti-GAP-43 antibody was used for *b*. Control PC12 cells of this variant expressed undetectable levels of GAP-43 and CAT immunoreactivity. Scale bar, 25 μm.

METHODS. PC12 cells were transferred to poly-D-lysine-coated coverslips 24 h before immunofluorescence in the presence of 50 μg ml^{-1} NGF, fixed with 3.7% formaldehyde for 7 min, and made permeable with 0.1% Triton X-100 for 3 min. The samples were blocked with 4% BSA in PBS for 1 h, incubated for 1 h in primary antibody, rinsed with PBS, incubated in 0.3% H_2O_2 in PBS for 15 min (to reduce background), rinsed again and incubated for 1 h in secondary antibody. After washing with PBS several times, coverslips were rinsed with water and mounted with Gelvatol containing 0.4% n-propyl gallate to decrease bleaching. Immunofluorescence was not detectable above background when cells did not contain specific antigens or when the primary or secondary antibodies were omitted.

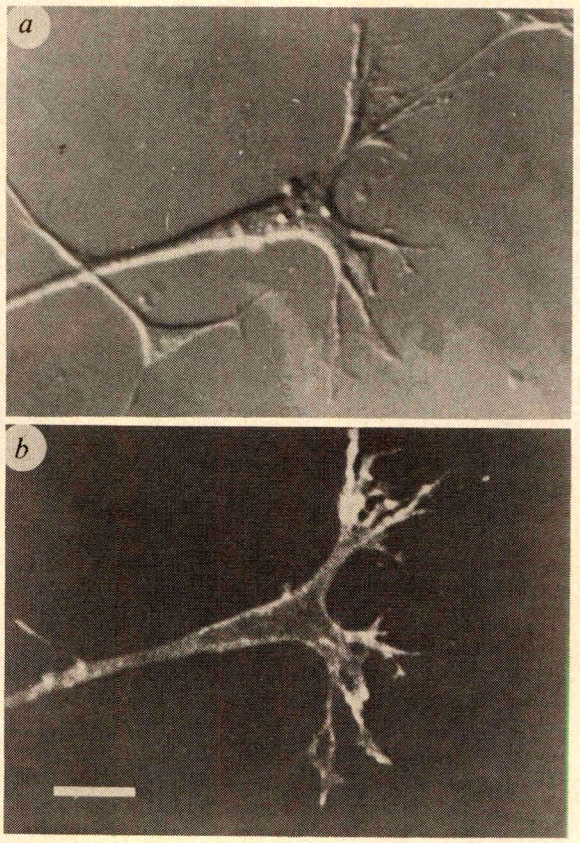

FIG. 4 Localization of $GAP_{40}CAT$ in the growth cone of a PC12 cell. A high power comparison of PC12 cells expressing $GAP_{40}CAT$ viewed with Nomarski optics (top) and scanning confocal immunofluorescence, labelled with anti-CAT antibodies (bottom). Cells had been treated with NGF for 7 days. one growth cone is brightly labelled, but the smaller one is not. Unequal labelling of different growth cones, even of the same cells, occurs for native GAP-43 in neurons[30] and did for the cells here. Comparison of the two images shows that filopodia are especially labelled. Similar results were seen for $GAP_{10}CAT$ (data not shown). Scale bar, 5 μm.

METHODS. For high resolution confocal microscopy, the cells were fixed with freshly made 4% paraformaldehyde and 0.5% glutaraldehyde, which was essential to preserve the fine structure of the filopodia, and then with 0.1% Triton X-100 for 3 min and 2 mg ml^{-1} sodium borohydrate in PBS for 10 min. Confocal analysis used a BioRad MRC-500 scanning confocal imaging system and a Zeiss Axioplan microscope.

but not with sodium chloride, calcium chloride or EGTA (data not shown). Thus, the nature of this membrane binding was similar to that of native GAP-43 in rat brain[11–14].

We investigated the cellular distribution of GAP-43 and the GAP-CAT chimaeric proteins in nerve growth factor (NGF)-treated transfectants of PC12 cells by confocal microscopy to determine whether the N-terminus accounts for the growth-cone enrichment of GAP-43 in neuronal cells. In this assay, CAT remained cytosolic (Fig. 3*a*), whereas GAP-43 was distributed in a punctate pattern with notable enrichment in many growth cones (Fig. 3*b*), a pattern similar to that of native GAP-43 in neurons. The N-terminus of GAP-43, which was fused to CAT, caused the resulting fusion protein to acquire a distribution that closely resembled that of GAP-43 itself (Fig. 3*c*, *d*). Perinuclear labelling for both GAP-43 and the chimaeric protein was detected at a low level, and may have been due to localization to the Golgi, as has been observed for native GAP-43[16]. Glutaraldehyde fixation provided better histological preservation of the finer processes of the growth cones, and revealed that the chimaeric protein accumulated especially within filopodia (Fig. 4).

Thus, the first 10 amino acids of GAP-43 suffice to direct the cellular distribution of GAP-43. We are not aware of other proteins that have a sequence closely related to the GAP-43 N

terminus, although at least one other non-integral membrane protein that accumulates in growth-cone membranes, SCG 10 (ref. 17) has two cysteines in close proximity (at positions 22 and 24). In polarized epithelial cells, different proteins accumulate in the apical and basolateral plasma membranes[1,18,19], a process believed to depend on sorting signals in the protein, similar to the signals that direct traffic of membrane- and secreted proteins to their particular destinations[20–22]. For epithelial cells, such signals would also recognize different regions of the plasma membrane as apical or basolateral. In neurons, the growth-cone membrane is also distinctive, although not unique, in its protein make-up. One interesting possibility is that the growth-cone membrane has binding sites that recognize and enhance the binding of the palmitylated N-terminus of GAP-43. Although possible, it seems less likely that the palmitylated residues interact with the lipid bilayer directly, because that would probably cause a more uniform membrane distribution for GAP-43. Along these lines, the fatty acid moiety of another acylated protein, N-myristylated VP4 of the poliovirus, has been shown by X-ray diffraction to interact with specific amino-acid residues of other viral proteins and not with the lipid bilayer[23,24]. Because GAP-43 and GAP–CAT fusion proteins bind to the membrane of non-neuronal cells, similar or identical binding sites must be present in other cells types. However, because GAP-43 is neuron-specific, these sites would presumably be targets for different proteins in non-neuronal cells. Sorting and selective transport, however, are as likely to account for growth-cone accumulation[31] as is the existence of specialized membrane binding-sites.

It is notable that the sorting domain of GAP-43 caused enrichment especially in many filopodia. This is the normal location of GAP-43 in these cells, as shown by electron microscopy[16]. Given the previous observation that transfected GAP-43 can enhance the propensity of non-neuronal cells to extend filopodia[15], it will be of interest to correlate GAP-43 location with the motile activity of particular filopodia. Finally, the sequence described here may be useful in the delivery of histological markers or other agents to the growth-cone membrane. □

Journals for 1990

Biomedical Chromatography

An international journal devoted to research in chromatographic methodologies and their applications in the biosciences.
Editors-in-Chief: **Elizabeth F. Hounsell and Chang Kee Lim**
ISSN: 0269-3879. Volume 4 1990 (6 issues).
£140 ($238).

Journal of Molecular Recognition

An international journal devoted to research on specific molecular recognition in chemistry, biology, biotechnology and medicine.
Editor-in-Chief: **Irwin M. Chaiken**
ISSN: 0952-3499. Volume 3 1990 (6 issues).
£149 ($253).

NMR in Biomedicine

An international journal devoted to the development and application of NMR spectroscopy *in vivo*.
Editor-in-Chief: **John R. Griffiths**
ISSN: 0952-3480. Volume 3 1990 (6 issues).
£155 ($263).

Phytochemical Analysis

An international journal of plant biochemical techniques.
Editor-in-Chief: **Barry V. Charlwood**
ISSN: 0958-0344. Volume 1 1990.
(3 issues commencing mid-1990).
£82 ($139).

Phytotherapy Research

An international journal devoted to medical and scientific research on plants and plant products.
Editor-in-Chief: **Fred J. Evans**
ISSN: 0951-418X. Volume 4 1990 (6 issues).
£127 ($215).

Rapid Communications in Mass Spectrometry

An international journal devoted to the rapid dissemination of up-to-the-minute research in mass spectrometry.
Editor-in-Chief: **John H. Beynon, FRS**
ISSN: 0951-4198. Volume 4 1990 (12 issues).
£132 ($225).

MOLECULAR AND CELLULAR PROBES

The Location, Diagnosis, and Monitoring of Disease by Specific Molecules and Cell Lines

Editors-in-Chief

C. N. Hales, *U.K.*

R. H. Yolken, *U.S.A.*

Research Areas Include

• Detection and measurement of specific molecules by polynucleotides, monoclonal antibodies, and cloned hybridomas or cell lines • Improved methods for the generation or detection of signals from these probes *in vivo* or *in vitro* • Improved strategies for the production of these probes • Animal models used as tests of the probes

Volume 3 (1989), 4 issues ISSN 0890-8508
Full Rate: £64.00(U.K.only)/U.S.$120.00(Overseas)
Personal Rate: £32.00(U.K.only)/U.S.$56.00(Overseas)

MICROBIAL PATHOGENESIS

Molecular and Cellular Biology of Infectious Disease

Editors-in-Chief

P. H. Mäkelä, *Finland,* **A. Haase,** *U.S.A.*

J. Young, *U.S.A.*

Research Areas Include

• Pathogenesis • Virulence factors • Host susceptibility or resistance • Immune mechanisms • Identification, cloning, and sequencing of relevant genes • Genetic studies • Viruses, prokaryotic organisms, and protozoa

Volumes 6-7 (1989), 12 issues ISSN 0882-4010
Full Rate: £144.00(U.K.only)/U.S.$272.00(Overseas)
Personal Rate: £52.00(U.K.only)/U.S.$88.00(Overseas)

FOOD MICROBIOLOGY

Editor

C. Batt, *U.S.A.*

Associate Editor

C. Dennis, *U.K.*

Research Areas Include

• Application of chemical and physical approaches to food microbiology • Biotechnological aspects of established processes • Food spoilage and safety • Predictive microbiology • Production of fermented foods • Rapid methodology • Use of novel microbial processes to produce flavours and food-related enzymes

Volume 6 (1989), 4 issues ISSN 0740-0020
Full Rate: £60.00(U.K.only)/U.S.$118.00(Overseas)
Personal Rate: £30.00(U.K.only)/U.S.$59.00(Overseas)

SERODIAGNOSIS AND IMMUNOTHERAPY IN INFECTIOUS DISEASE

Editors

J. P. Burnie, *U.K.,* **J. D. Williams,** *U.K.*

L. S. Young, *U.S.A.*

Research Areas Include

• Sensitive immunological techniques such as enzyme-linked immunosorbent assays and radioimmunoassays • Rapid serodiagnostic tests for viral infections • Improved techniques for diagnosing bacterial infection where the microorganism is dangerous, difficult, or slow to grow • Improved diagnosis of fungal infections with serological tests

Volume 3 (1989), 6 issues ISSN 0888-0786
Full Rate: £74.00(U.K.only)/U.S.$144.00(Overseas)
Personal Rate: £37.00(U.K.only)/U.S.$72.00(Overseas)

JOURNAL OF AUTOIMMUNITY

Editor

J. F. Bach, *France*

Co-Editors

I. M. Roitt, *U.K.,* **C. R. Stiller,** *Canada,*

N. Talal, *U.S.A.*

Research Areas Include

• The mechanism of self-recognition • Genetics • Epidemiology of autoimmune diseases • Etiology, pathophysiology and treatment of autoimmune diseases • Regulation of autoimmune response • Experimental autoimmune diseases • Rheumatology • Dermatology • Endocrinology and diabetes • Nephrology • Haematology • Immunopharmacology • Diagnostic autoantibody tests

Volume 2 (1989), 6 issues ISSN 0896-8411
Full Rate: £78.00(U.K.only)/U.S.$148.00(Overseas)
Personal Rate: £39.00(U.K.only)/U.S.$74.00(Overseas)

Free sample copies are available upon request.

Journals from

ACADEMIC PRESS

New in 1990

JOURNAL OF VISUAL LANGUAGES AND COMPUTING

Editors

S.K. CHANG
University of Pittsburgh, U S A

S. LEVIALDI
University of Rome, Italy

The ***Journal of Visual Languages and Computing*** is a forum for the advancement of visual languages and its implications to the art of computing. The journal publishes research papers, state-of-the-art surveys, and review articles.

Volume 1 (1990), 4 issues ISSN 1045 926X
In the U.K.: £60.00
All other countries: $120.00

New in 1989

KNOWLEDGE ACQUISITION

Editors

B.R. GAINES
Center for Person-Computer Studies, Calgary, Canada

J.H. BOOSE
Boeing Computer Center, Seattle, U.S A

Knowledge Acquisition aims to provide those developing knowledge-based systems with access to state-of-the-art research on tools, techniques, methodologies, and foundations for knowledge acquisition from experts, texts, and other sources of human knowledge.

Volume 2 (1990), 4 issues ISSN 1042 8143
In the U.K.: £60.00
All other countries: $120.00

New in 1989

EUROPEAN JOURNAL OF IMPLANT AND REFRACTIVE SURGERY

Editor

Emanuel Rosen
Manchester, U.K

The ***European Journal of Implant and Refractive Surgery*** is published on behalf of the European Intraocular Lens Implant Council (EIIC) by Baillière Tindall in London. It publishes original full papers and rapid communications in English dealing with all aspects of ocular implant surgery, refractive surgery, and topics of related interest.

Volume 2 (1990), 4 issues ISSN 0955 3681
In the U.K.: £60.00
All other countries: $114.00

New in 1989

BINARY: COMPUTING IN MICROBIOLOGY

Editors

J.W.T. Wimpenny
University College, Cardiff, U K.

M.I. Krichevsky
National Institute of Dental Research, Bethesda, Maryland, U S.A.

BINARY is a new international journal which will publish a broad range of articles relating to all aspects of computing as applied to microbiology. Original papers are welcomed from those working in general and clinical microbiology, and biotechnology.

Volume 2 (1990), 6 issues ISSN 0266 304X
In the U.K.: £40.00
All other countries: $80.00

Sample copies and privileged personal rates are available for some journals.

Can you afford to miss the latest journals from BSP?

New for 1990!

ANTIVIRAL CHEMISTRY AND CHEMOTHERAPY (Volume 1)

Editor-in-chief *John Oxford, London Hospital Medical College, UK*

A **major** new journal publishing the results of important original research concerned with the biochemistry, mode of action, chemistry, pharmacology and virology of antiviral compounds

Published bimonthly, ISSN 0956-3202

Subscription rates for 1990 Institutional £99 50 (UK), US$210 00 (USA & Canada) and £120 00 (elsewhere) Personal £49 50 (UK), US$105 00 (USA & Canada) and £60.00 (elsewhere)

NETWORK: Computation in Neural Systems (Volume 1)

Editor *Daniel J Amit, Racah Institute, Jerusalem, Israel*

A joint venture with IOP Publishing Ltd

Network will provide a forum for integrating interdisciplinary research in the use of network models as a novel framework for understanding neural systems

Published quarterly, ISSN 0954-898x

Subscription rates for 1990 £110 00, US$180 00 Please address all orders and enquiries to *Journals Marketing Department, IOP Publishing Ltd, Techno House, Radcliffe Way, Bristol BS1 6NX, UK*

CYTOPATHOLOGY (Volume 1)

Editor-in-chief *Dulcie V Coleman, St Mary's Hospital, London, UK*

Affiliated to the British Society for Clinical Cytology

Reflecting the interests of cytopathologists and cytotechnologists alike, this journal will publish articles relating to those aspects of cytology which will increase our knowledge and understanding of the aetiology, diagnosis and management of human disease

Published bimonthly, ISSN 0956-5507

Subscription rates for 1990 £70 00 (UK), US$145 00 (USA & Canada) and £84 00 (elsewhere)

THE JOURNAL OF ENVIRONMENTAL PATHOLOGY, TOXICOLOGY AND ONCOLOGY

Newly acquired by BSP and published for the International Society for Environmental Toxicology and Cancer. The journal will feature articles describing research on toxins and other man-made artifacts which affect human health and disease

Published bimonthly, ISSN 0731-8898

Subscription rates for 1990 Institutional US$149 50 (USA), US$167 50 (Overseas, surface mail) and US$187 00 (Overseas, air mail) Personal US$110 00 (USA), US$128 00 (Overseas, surface mail) and US$147 50 (Overseas, air mail)

All orders and requests for free specimen copies should be addressed to *Blackwell Scientific Publications Inc , Three Cambridge Center, Suite 208, Cambridge, MA 02142, USA*

Also

ANTARCTIC SCIENCE

Now in its second volume!

Editor-in-chief *David W H Walton, British Antarctic Survey, Cambridge, UK*

Essential reading for all scientists involved in Antarctica, this journal provides a focus for the interdisciplinary interests that characterise Antarctic research Antarctic Science is interesting, original and topical, and yet rigorous in its treatment of primary scientific data

Published quarterly, ISSN 0954-1020

Subscription rates for 1990 Institutional £55 00 (UK), US$115.00 (USA & Canada) and £66 00 (elsewhere) Personal £31 50 (UK), US$68 00 (USA & Canada) and £39 00 (elsewhere)

TERRA NOVA

Now in its second volume!

Editor *Robert Muir-Wood, University of Cambridge, UK*

"Just as there is only one Earth, there must be one unified Earth Science". Terra Nova contains research papers on any aspect of earth sciences research, and also news, book and software reviews, and longer review articles which explore issues and ideas in and beyond earth sciences.

Published bimonthly, ISSN 0954-4879

Subscription rates for 1990 £120 00 (UK), US$224 50 (USA & Canada), and £135 00 (elsewhere) **Membership of the European Union of Geosciences costs £30.00 and includes a subscription to Terra Nova.**

MOLECULAR MICROBIOLOGY

Editors *Chris Higgins, University of Dundee, UK, Gary Schoolnik, Stanford University School of Medicine, USA, and Tony Pugsley, Institut Pasteur, Paris, France*

Now in its fourth volume, this highly successful journal publishes **high quality** research papers addressing any microbiological question at the molecular level Molecular Microbiology includes papers describing the molecular biology, genetics and biochemistry of any microorganisms, prokaryotic or eukaryotic

Published monthly, ISSN 0950-382x

Subscription rates for 1990 Institutional £225 00 (UK), US$430 00 (USA & Canada) and £259 00 (elsewhere) Personal £69 00 (UK), US$99 50 (USA & Canada) and £79 50 (elsewhere)

CONSERVATION BIOLOGY

Now in its fourth volume!

Editor *David Ehrenfeld, Rutgers University, New Brunswick, USA*

Published for the Society of Conservation Biology, this journal has earned the respect of ecologists and conservationists around the world and is the fastest growing and **most influential** journal in the field today

Published quarterly, ISSN 0888-8892

Subscription rates for 1990 Institutional US$110 00 (USA), US$122 00 (Overseas, surface mail) and US$135 00 (Overseas, air mail) Personal US$67 50 (USA), US$79 50 (Overseas, surface mail) and US$92 50 (Overseas, air mail) Students US$29 50

All orders and requests for free specimen copies should be sent to *Blackwell Scientific Publications Inc , Three Cambridge Center, Suite 208, Cambridge, MA 02142, USA*

BSP -JOURNALS-

Blackwell Scientific Publications Ltd
Osney Mead, Oxford OX2 0EL, UK

Publishing and perishing?

John B. Merriman

More journals, and more expensive journals, are chasing customers with reduced spending power. Scientist themselves are in part responsible.

ONE of the great commercial mysteries of the 1980s is the production of more and more scientific journals for markets that have less and less ability to pay for them. Something is wrong. Library budgets, in Britain and the rest of the world, have not kept pace with the proliferation of new titles and price increases, and publishers seem to be running faster and faster just to keep still.

Librarians in the academic world, especially the United States, have been the most vocal in expressing their worries, but other libraries — corporate, special and so on — also have their difficulties. Subscription agents, too, are concerned, and I should first briefly explain the perspective from which I view the matter of journal publication and purchase.

Traditional links

The traditional links in the serials-information chain are author–publisher–agent–librarian–reader. The main players are the publishers and librarians, the agents being in the middle of the sandwich. Our role is to provide a full service for journal procurement, irrespective of country or language. For libraries, agents bring together all their subscriptions and offer other services (such as providing information about new journal titles, price increases and delays in publication, dealing with missing issues, and serials management systems) to help them manage their serial collections. For publishers, agents act as order consolidators. That about 80 per cent of subscriptions ordered from publishers come through agents is evidence that the role of middle-man is a valuable one. In spite of the increased numbers of titles available, however, the change of climate since the great journal bonanza of the 1960s and early 1970s has meant that subscription agents have seen their volume growth level cut as budget cancellations have taken effect.

To what extent have journal prices increased? Blackwell's Periodicals Price Index, published each year in the May issue of the *Library Association Record*, surveys 2,007 primary journals, of which 1,165 are in science, technology and medicine. In 1989 the increase over 1988 was 7.43 per cent, but this figure was influenced by beneficial exchange rates for overseas journals. The increase for British-produced journals was 10.77 per cent.

More telling is the comparison, shown in Table 1, of the average prices of the top ten most expensive subject areas with those of five years ago. (Science and technology journals are far more costly than others; in 1989 their average price is £214, as opposed, for example, to £123 for medical journals.) In some areas, the increases are about double the increase in the Retail Price Index over the same period.

On the other side of the coin are library budgets. The University, College and Professional Publishers Council of the Publishers Association has recently produced a report on book and journal spending by British universities and polytechnic libraries in the years 1978–79 to 1986–87. In universities spending has fallen by nearly 25 per cent in real terms over that period; the loss is £17,000 per university — nearly £1 million The polytechnics have suffered less severely, with a reduction of 9 per cent, but they have suffered nonetheless.

The main conclusions of the report are:

> Expenditure on published materials, the basic resource for teaching and research, continues to decline in real terms and now, in some cases, in cash terms. The persistent and detrimental effects of funding cuts in this area of provision bring periodical cancellations and fewer book purchases and undermine the strength of research collections so vital to the support of present and future scholars.
>
> The economic constraints on library purchasing will leave holes in the library collections that can never hope to be filled in the future. It is inevitable that in the struggle to maintain a reasonable level of book purchases, university libraries will be forced to seek more cancellations of subscriptions to add to the many thousands they have already cut since 1981–82.

Another indicator of the condition of journal publication and purchase comes from the same report In 1987 the number of titles available rose by 12 per cent over the previous year, but the number of subscriptions for each journal fell, on average, by 10 per cent. Here is evidence of the vicious circle whereby a new journal will probably thrive only at the expense of another. Declining circulation figures mean higher prices, and more cancellations. And so it goes on. 'Twigging', the proliferation of journals in narrower and narrower subject areas, is also involved. The overall pattern is reflected in a graph that appeared in *Learned Publishing* in January 1989 (Fig. 1 — see over).

Combined squeeze

The overall consequences of the combined squeeze from the increased number of titles, increased subscription prices and reduction in library budgets can be seen in figures from Canada — over the past ten years, Canadian librarians have cancelled 40,000 subscriptions worth some $4.2 million. They and their counterparts throughout the world are asking whether we have reached a position in which the existence of many journals is for the benefit of contributors only, not that of readers.

The standard villains in the drama are the commercial publishers (some of them said to be more villainous than others). The accusations brought against them by the librarians are those of over-producing, over-pricing and, in some cases, of making excessive profits. Concern is also expressed at the concentration of power in just a few large companies who, it is said, hold the scientific community to ransom. But the publishers themselves cannot be the only scapegoats for a system which is characterized by the insatiable demand of the ever-growing numbers of scientists. That demand, of course, is for scientists to get their work into print, not only (no doubt) in the cause of scholarship but to produce the maximum number of papers with a view to their prospects of obtaining tenure, promotion or a grant.

In popular conception, the forces of good ranged against the commercial publishers are gathered under the banners of the university presses and learned societies. Publication of a greater proportion of journals through such bodies, the argument runs, would result in more responsible publishing and lower subscription rates.

So is the answer to the crisis to be found with the learned societies? I doubt it. Like commercial publishers, if they are to

Table 1 Average prices of journals in the top ten most expensive subject areas, 1985 and 1989

	1985	1989	Increase	
1 Biophysics, biochemistry, microbiology	£390	£552	+£162	(42%)
2. Chemistry	£379	£529	+£150	(40%)
3 Physics	£306	£450	+£144	(47%)
4. Nuclear science & technology	£329	£357	+£ 28	(9%)
5 Biology	£254	£339	+£ 85	(33%)
6. General technology	£175	£259	+£ 84	(48%)
7 Astronomy & astrophysics	£166	£216	+£ 50	(30%)
8. Polymers, paint, rubber & plastics	£137	£209	+£ 72	(53%)
9. Surgery, anatomy & physiology	£168	£208	+£ 40	(24%)
10. Electronics, electrical engineering, aeronautics	£134	£187	+£ 53	(40%)

survive they must make profit (or surplus, call it what one will) and charge for subscriptions in advance, so creating a cash reserve at the beginning of each year. As charitable institutions, in Britain they have substantial tax advantages. Moreover, many learned societies, both in Britain and the United States, still prefer to publish their journals through the commercial sector, rather than go it alone. Naïveté is unlikely to be the only reason.

At Blackwell's we have surveyed our top ten commercial publishers, and our top ten learned societies who publish independently; for the international subscription agents those two groups

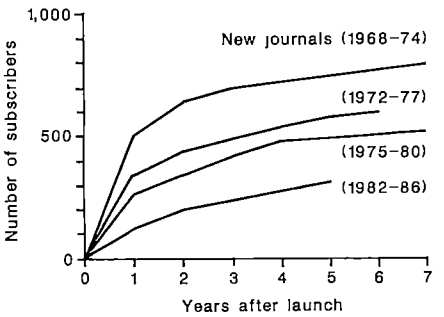

Fig 1 Decline in circulation figures for new journals. (From A. Stevens *Learned Publishing* **2**, 1–7; 1989.)

will represent a large proportion of their turnover, and their lists include a high proportion of primary journals. For 1989 over 1988 (not taking account of exchange-rate variations) the commercial publishers increased their prices by 10.57 per cent, the learned societies by 10.40 per cent Nor are overall prices notably different — £207.78 for commercial publishers, £217.85 for learned societies.

I referred earlier to a 'crisis', which seems to me to be not over-stating the case — something, at some stage, has surely got to give in the dissemination of information through journals. Various courses of action are being advocated. More careful use of the present system by evaluating usage of individual titles against their price, replacement of expensive journals with cheaper ones, encouraging scholars not to serve on the editorial boards of journals that do not adopt realistic pricing policies and, in the longer term, the establishment of an information-clearing house to give libraries access to pricing policies, current journal rates, and proposed acquisitions and cancellation plans of other libraries. More radical would be the adoption of alternative forms of communication, in particular those employing electronics.

Meantime the demand to publish grows. No one — not least the scientific community — seems prepared to give way first. □

John B. Merriman is Director of the Periodicals Division, B. H Blackwell Ltd, PO Box 40, Hythe Bridge Street, Oxford OX1 2EU, UK

New journals review 1989

THE following explanation is offered to those wishing to know the basis on which the journals mentioned in the following pages were chosen for review.

In *Nature*'s previous journal supplements*, two principles determined the time criteria for a publication to be eligible for review in a particular year. First, that at least four different issues should have been published, to give reviewers a reasonable sample on which to base a judgement. Second, that most new journals start as quarterlies though they often later become more frequent.

Thus in last year's review supplement journals first appearing between June 1986 and May 1987 were considered for review. The first date was carried forward from the previous year; the second meant that four issues of a quarterly would (in principle) be available to reviewers at the time of commissioning reviews in June 1988.

Publishers and others have pointed out that journals with a schedule more frequent than quarterly could hardly count as 'new' under this system, in terms of the numbers of issues published, by the time they came to be reviewed. So for 1989 the time criteria were changed — any journal published after May 1987 and with four issues available in May 1989 was eligible for review.

Other criteria were that the journal should appear at least three times a year, and that the main language used should be English Abstracts publications and newsletters are not reviewed. Several titles eligible for review are not covered here for one reason or another, and a list of them appears on p. 370.

The brief given to reviewers was to limit themselves to comment on the publications sent to them, and to avoid discussion of general questions of periodical publishing. Opinions expressed in the reviews are based on a sample of issues, and apply to mid-1989 at the latest. As in previous years, the preponderance of journals in the biological sciences reflects the bias of material submitted for review.

Details of editors and frequency of publication, and the subscription rates appearing at the top of each review, are given in most instances for 1990. This information is not complete in all cases, and readers interested in subscribing to a particular journal should check the rates with the publisher concerned. □

Planting ideas in the literature

Charlie Shaw and Phil Gates

The Plant Cell. Editor Robert B. Goldberg. *American Society of Plant Physiologists. 12/yr. $550 for* The Plant Cell *and* Plant *(institutional), $100 (personal)*
Sexual Plant Reproduction. Managing editor H F. Linskens. *Springer-Verlag. 4/yr. DM 270; North America $160.*

THE recent expansion in the plant sciences, particularly in molecular biological work, has largely gone unnoticed by the front-line publications such as *Cell, Nature* and *Science*. The paucity of 'plant' papers in these journals has contributed directly to the failure of animal and microbial scientists to recognize the massive advances made in plant molecular biology (there are, for example, more transgenic plants than animals in existence). The void has been partly filled by the excellent *EMBO Journal*, which has always allocated a significant proportion of its space to 'plant' articles. Another, more specialized journal in this field is *Plant Molecular Biology*, but it has yet to reach real prominence.

Into the breach have stepped two new publications. *The Plant Cell* is a high-impact glossy journal, backed by the American Society of Plant Physiologists and sister to *Plant Physiology*. By the editor's own admission, *Cell* has been taken as the benchmark and the quality of reproduction, format and science are generally of a high standard. The journal was launched specifically to address the interface between molecular, cellular and developmental approaches in plants, and thus far it appears to be fulfilling this role. Most of the papers address molecular questions (the majority of them also involving some element of cell biology and development) and most concern higher plants, though the journal also aims to cover fungi and protists relevant to plant problems.

The editor is meeting his goal of rapid publication (six to eight weeks from acceptance to publication) He has also shown that he is not afraid of controversy by entering into the debate over a leading article in *Cell*, which prefaced an issue belatedly devoted to plant reviews and which was patronizing in tone and poorly researched. *The Plant Cell* has already attracted a good number of subscriptions and looks set for a healthy future, although the decline in issue size is disturbing and more colour figures and cellular/developmental papers are needed. Unless other high-profile journals increase their 'green' content, it should become the place that all plant molecular biologists look to first

Papers on such varied topics as pollen transformation, sexual induction in *Volvox*, pollination methods for lily hybridization and a review on thermogenicity in *Arum* have appeared in the first few issues of *Sexual Plant Reproduction*, confirming the editors' stated intention to reflect the transdisciplinary nature of research in plant reproduction. Hitherto, published work on the subject has been widely dispersed in the literature. This new journal, with an editorial board that constitutes a who's who of research workers in the field, should act as a catalyst to greater progress in our understanding of plant reproductive processes at every level.

New techniques in plant molecular biology have already advanced our understanding of reproductive processes, building on foundations laid by biochemists, physiologists and geneticists, and it is slightly worrying that several relevant molecular biological papers have appeared in *The Plant Cell*, rather than *Sexual Plant Reproduction*. It would be a pity if the Springer journal's potential role in integrating knowledge from widely varying experimental disciplines were to be prejudiced by molecular-orientated authors being dazzled by the high-impact format of *The Plant Cell*. □

Charlie Shaw and Phil Gates are in the Department of Biological Sciences, University of Durham, South Road, Durham DH1 3LE, UK.

Off target

Peter H. Williams

Molecular Microbiology. Editors Chris Higgins and Gary Schoolnik *Blackwell Scientific. 12/yr. UK £210, North America $395, elsewhere £241 (institutional); UK £69, North America $132, elsewhere £79.50 (personal).*

THERE is something unequivocal and uncompromising, even menacing, about the title *Molecular Microbiology*. It permits no ambiguity. Not for me, it seems to say, the sweeping breadth of the *Journal of General Microbiology* or the *Journal of Bacteriology*; none of the vagueness suggested by *Infection and Immunity* or the *Journal of Infectious Diseases*. If your work is both molecular and microbiological, it says, then this is the place for you; if not, bug off

The scope of the journal is simply and precisely what the title says it is — molecular aspects (protein structure, enzymology, immunology, gene organization and mapping, regulation, DNA topology and so on) of micro-organisms from *Anabaena* to *Yersinia* (doesn't anyone work on *Zymomonas*?), with, it has to be said, an emphasis on pathogenicity. Papers can be anything from 1,400 to 7,000 words long, although most are much less than the upper limit, short review articles ("MicroReviews"!) are invited on topics of particular current interest, and each issue bears a cover photograph (generally in colour) relevant to one of the papers it contains. Notes of up to 2,500 words are also accepted. But their format is so like that of a regular paper, and the speed of publication not significantly faster, that there seems little advantage in having a distinct category

Acceptable manuscripts appear in print a creditable six to seven months after submission, and, unlike the journals of the American Society for Microbiology that constitute its main rivals, there are no handling charges and the first 50 reprints are free So far, the general quality of the articles has been very high, in terms of both scientific merit and standard of writing. The quality of presentation is also excellent; the layout, with well-spaced lines and text in two columns per page, is particularly attractive and easy to read, and the cover pictures are eye-catching, if not always very original. If quality alone is the recipe for success, then this new journal is here to stay. But is it?

The problem, it seems to me, is that *Molecular Microbiology* cannot be said to fill a gap. Its scope is almost identical to that of *Microbial Pathogenicity* (another newcomer currently emphasizing molecular studies), and all the papers published so far would have found appropriate resting places in other journals of broader appeal *Molecular Microbiology* claims on its cover to incorporate *Microbiological Sciences*, a journal that successfully disseminated the message of new technology in well-written reviews to a wide, non-specialist audience. In changing its name, this journal has also changed its nature to the extent that it no longer fulfils this function; it is now aimed unashamedly at a well-defined cross-disciplinary group which includes microbiologists who ask molecular questions and molecular biologists who happen to work with micro-organisms

Surely, though, the real target of much of the work published here is, or should be, future practitioners of molecular methods — clinical microbiologists, for example, who may not yet be asking molecular questions, but who would be if the relevant information were intelligibly presented. I fear that *Molecular Microbiology* may have missed this target. □

Biothis and biothat

Walter Gratzer

Chinese Journal of Biochemistry and Biophysics. Chairman of the editorial committee Lin Qi-Shui. *Allerton, New York. 4/yr. North America $265, elsewhere £280.*

The FASEB Journal. Editor-in-chief William J. Whelan. *Federation of American Societies for Experimental Biology. 15/yr. US $200, elsewhere $240 (institutional); US $90, elsewhere $130 (personal), US $45, elsewhere $85 (student).*

I WAS recently told — and I do not vouch for the veracity of the tale — that an occidental author, having sent his highly rejectable manuscript to an oriental journal, received the following response: the editors, he was informed, had found his paper so overwhelmingly superior that anything their modest organ could aspire to publish thereafter would appear irredeemably unworthy. For the sake of their survival, they were therefore desolated to have to decline his offering. The point of the story is that submissions from the outside world to parochial journals are a rare enough event to throw the editors off balance, and when such papers do arrive they are unlikely to be the sort of contribution over which the international journals of the West would fight.

So the journals of the learned societies of Europe, Asia and Africa stay hidden in decent obscurity. There are exceptions (such as arguably the *Journal of Biochemistry* of Tokyo and the *Biochemical Journal*), but in general a Ruritanian biochemist with any pride or confidence in his work will want to bring it before a wider public than is reached by *Ruritanica Biochimica Acta* (especially if published in the Ruritanian language). What then, if any, is the place of national journals? Primarily, it seems to me, they are an assertion of a national scientific identity and a focus for the local research community.

The launching of the new English translation of *Chinese Journal of Biochemistry and Biophysics* (sometime *Acta Biochimica et Biophysica Sinica*) is perhaps a signal that the renaissance of biological science in China is complete — that its output can fill a respectable journal of its own. This the first four issues undoubtedly demonstrate: the coverage is representative of the biochemistry and biophysics of the 1980s and the substance is solid. It is certainly not given over, as might have been feared, to pharmacologically active products of rare oriental plants: the pages are spattered with spectra of many kinds, with restriction maps and with expression vectors. It is all respectable, if occasionally lightweight stuff.

Everyone will wish the journal good speed. It reflects a remarkable achievement. Yet one cannot help but wonder whether what will really count for Chinese science, both inside the country and abroad, may not be the papers that the authors will want to stand beside the best in the international journals.

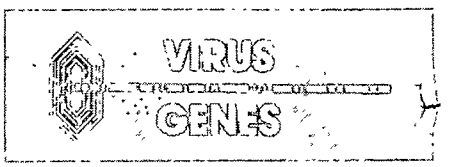
The *FASEB Journal* (with somewhat similar subject matter) is an altogether different proposition — its precursor, the *Federation Proceedings*, had been going for 45 years, and had, it seems, the widest circulation of any biological journal. *Fed. Proc.* published a desultory trickle of conference proceedings the year round and came to life every spring with the Federation abstracts (usually some 7,000 of them from 20,000 participants), which all biological scientists scan keenly, to see what the opposition is up to. To judge from the President's introduction in the first issue of the reconstructed model of the *FASEB Journal*, two years ago, it must suddenly have dawned on the FASEB committee that they had an existing clientele, all with open mouths, down which could be thrust something more nutritious than conference reports and abstracts.

It was, on the face of it, a foolproof formula for success. What then have the editors made of their opportunity in the intervening years? The reviews are maintaining a decent standard with only an occasional lurch downmarket; the papers are seldom notably exciting or trendy, but those I can judge are of unexceptionable quality. But there are only five of them in each monthly issue, so the President, in seeking, as he avows, to help out *Nature* and *Science* in the struggle against the ever-advancing flood of publication, is bailing with a teaspoon.

Why only five a month? Is the editorial board rejecting hundreds in the interests of lofty standards? Is there a dearth of manuscripts? Or is it simply that they cannot afford more pages? Prospective contributors need to know. □

Walter Gratzer is in the MRC Cell Biophysics Unit, King's College London, 26–29 Drury Lane, London WC2B 5RL, UK

Small talk



Jeffrey W. Almond

Virus Genes. Editor-in-chief Yechiel Becker. *Kluwer. 4/yr. Dfl.251, United States $126 (institutional); Dfl.150, US $60 (individual).*

IN VIRUS research during the 1980s there has been a strong emphasis on analysis of the structure and function of virus genes. This is hardly surprising, given the advances in recombinant DNA technology over this period and the realization that a detailed knowledge of virus genes is fundamental to our understanding of all aspects of virus biology. Whether this trend justifies the introduction of a new journal which aims "to serve as a platform for the publication of experimental and computer studies on genes from all virus genera and families" remains open to question. Papers dealing with virus genes already dominate most established virology journals and will continue to do so in the forseeable future.

Virus Genes is a small journal, introduced in 1987, with most issues so far containing fewer than ten papers. The journal publishes short communications and reviews as well as full papers, and welcomes letters to the editor-in-chief. In addition, some of the issues contain editorial comment and/or a rather interesting "Viewpoint" section which deals with a contentious issue of current interest in virology, usually chosen by the editor-in-chief. Although the quality of production is acceptable, the small format means that some figures and diagrams are cramped and difficult to read. There is also an annoying inconsistency in the layout of the references, some authors providing titles and others not.

In spite of my initial scepticism I have been mildly impressed by the quality of the papers published to date, although some of them seem to assume a wider remit than just virus genes. The prospects for success of this journal, however,

depend heavily on the quantity as well as the quality of the contributions it will attract. At the moment it is not a first-division journal because it does not contain enough material to make it a compulsory purchase for libraries. Moreover it does not have a unique position in the virology literature and is unlikely to establish one.

A glance at a random issue of one of the better virology journals revealed in excess of 40 papers, at least half of which were concerned with virus genes. Unless this new journal can attract a substantial proportion of these papers it is unlikely to establish itself in the top flight. I cannot see this happening with a quarterly publication schedule and with publication times certainly no shorter than those of its main competitors. □

In sequence

Gunnar von Heijne

Protein Sequence & Data Analysis. Chairman of the executive editors A. Tsugita. *Springer-Verlag. 6/yr. DM 610, $353.*

MOST readers of *Protein Sequence & Data Analysis* are probably not aware that the cover logo depicts the amino-terminal sequence of tetanus toxin. It is not clear to me whether some symbolic significance should be attached to this choice; but it was a rather unhappy one, in that this protein sequence is derived from cDNA data even though the journal portrays itself as the bulwark of the protein sequencers in an ocean of DNA-jocks.

The opening editorial states that the journal has three main objectives: to provide a forum for the publication of pure protein-sequence data that would not readily be accepted by other journals; to provide a medium for the advancement of theoretical sequence data analysis; and to print recent entries from the Protein Identification Resource (PIR) Protein Sequence Database as a service to scientists who do not have ready access to computerized databanks.

Judging by the number of pages devoted to each of these objectives, the editors seem to have opted for a 1:1:1 ratio. Thus a typical issue will contain something like five full papers, one short note and 60–70 pages of PIR entries.

Overall, the scientific standard of the papers is on a par with those found in such publications as *European Journal of Biochemistry, Nucleic Acids Research, Computer Applications in the Biosciences (CABIOS)* and *Journal of Molecular Evolution*. *Protein Sequence & Data Analysis* may thus evolve to become a focal point for work dealing with the experimental and theoretical analysis of protein sequences *per se*, although papers of this kind are certainly also found in many of the main biochemical journals.

On a more critical note, I think that the large space devoted to PIR databank entries could be more profitably filled in other ways — indeed, if one can afford a subscription to *Protein Sequence & Data Analysis* one should probably first think of spending the money on a cheap PC equipped with the appropriate software and databanks. After all, it was my computer, not the journal, that identified the tetanus toxin logo for me. □

Defence work

Fred S Rosen

Journal of Autoimmunity. Editor J. F. Bach. *Academic. 6/yr. UK £98, elsewhere $186 (institutional); UK £49, elsewhere $93 (personal).*

Autoimmunity. Editor Terence J. Wilkin. *Harwood. 4 issues/volume. $222 (institutional), $144 (university library); $72 (personal)*

Current Opinion in Immunology. Editors I. M. Roitt, P. Marrack and F. Alt. *Current Science. 6/yr. North America $200, elsewhere £120 (institutional); North America $95, elsewhere £55 (personal).*

Regional Immunology. Editor-in-chief J. Wayne Streilein. *Wiley. 6/yr. US $115, elsewhere $166 (institutional); US $80, elsewhere $110 (personal).*

DURING the past decade immunologists have made enormous progress in understanding the molecular basis of the immune response. The T-cell antigen receptors have been discovered and the genes encoding them have been mapped and sequenced. The mechanism whereby an antigen is converted into an immunogen has been elucidated. Crystallographic pictures have been obtained of class I histocompatibility molecules and they demonstrate the crevice to which immunogenic peptides bind before interacting with cytotoxic T lymphocytes.

This has galvanized the imagination of immunologists; the hypothetical has been made real. The complex interactions of cells of the immune system are now known to involve a large array of adhesion molecules, and an unforeseen network of receptors and ligands has come to light. Amid this wealth of discovery, autoimmunity or reactivity against self remains an unsolved mystery. Many diseases such as insulin-dependent diabetes mellitus, myasthenia gravis and systemic lupus erythematosus, to name but a few, are autoimmune phenomena, and research in autoimmunity has been rapidly expanding. In consequence, we have two new specialist journals dealing with the field, one published by Academic Press, the other by Harwood.

Journal of Autoimmunity is edited by J. F. Bach of the Hôpital Necker in Paris, assisted by I. M. Roitt of London, England, C. R. Stiller of London, Canada, and N. Talal of the University of Texas. In further support is an editorial board of authoritative international figures. The journal is devoted principally to original submissions, which to date have been of a very high standard. Reports from meetings have also been included, and like the rest of the contents they are published quickly; for example the proceedings of the First International Meeting on Immunointervention in Autoimmune Diseases appeared within six months of the meeting.

This journal appears to fill a need in an active field of research. With a modest personal subscription rate, it is good value for both researchers and clinicians. The other new entry into this arena, *Autoimmunity*, inspires no such confidence. Edited by T. J. Wilkin of Southampton General Hospital, it contains original submissions and also book reviews, invited reviews, brief meeting reports and hypotheses. But in both price and quality of the contents it does not fare well in comparison with *Journal of Autoimmunity*.

It is a daunting task to be familiar with the vast panoply of immunological literature. The publisher, Current Science, developed the innovative idea of scanning over 100 journals in immunology, publishing a list of the articles culled, and grouping them into discrete subjects such as innate immunity, immune response, immunodeficiency and so on. An authority in each field chooses several commentators who discuss the most interesting findings, and highlight and summarize the relevant articles.

Current Opinion in Immunology, the vehicle for this enterprise, succeeds only partially. There are two obvious prerequisites in such a vast undertaking. One is that the scanning of the journals must be complete and knowledgeably performed. I found several notable omissions, which led me to the conclusion that the job was not well done. The other is that the taste, authority and breadth of knowledge of the commentators have to be of the highest order. The reviews are wanting in this regard also.

Every other month two subjects are covered, such as immunity to infection and immunodeficiency or atopic allergy and autoimmunity. The format of the journal is pleasing and easy to read, and informative, original figures are reproduced. Each brief review is followed by a bibliography of relevant papers, which are graded by the reviewer as to their relative importance. After this appears a presumably complete list of the world literature on the subject discussed.

Overall supervision of the contents is not all it might be. I found three different discussions of the leukocyte adhesion deficiency in three separate issues; although this is a fascinating genetic defect, its overrepresentation is an example of imbalance in the journal's contents.

It was obviously an instance of monumental hubris to undertake this task. Its conceiver certainly ran the risk of invoking the wrath of the gods — or of those omitted in the scanning process. *Current Opinion in Immunology* is great

value for what it contains, but it would be worth twice the price if it also contained what has been omitted.

When I picked up *Regional Immunology* I had visions of reading about the niceties of immunity to kala azar in India or leishmania in Brazil. I was wrong — 'regional' here has something to do with the specialization of the immune system in different tissues such as the gut, the lung or the anterior chamber of the eye.

I was further surprised to find articles of high quality by authoritative investigators, but was hard pressed to find what was 'regional' about the contents. The journal publishes articles worthy of any good immunological journal; I suspect that the editor, J. W. Streilein of the Department of Microbiology and Immunology of the University of Miami, will find it difficult to maintain the circumscribed purpose of the journal as well as a continuous flow of high-quality original articles devoted to that purpose. □

Neuroregulation

Jennifer Altman

Glia. Editors-in-chief Bruce R. Ransom and Helmut Kettenmann. *Alan R. Liss. 6/yr. US $180, elsewhere $231 (institutional); US $75, elsewhere $105 (personal).*

Journal of Chemical Neuroanatomy. Editors Harry W. M. Steinbusch and A. Claudio Cuello. *Wiley. 6/yr. £160, $290.*

THE development of techniques for identifying chemical constituents of nervous tissue *in situ* has been one of the main sources of recent advance in functional studies of the nervous system Autoradiography, immunohistochemistry and *in situ* hybridization, together with transported markers, have provided a way of relating structure to function — by revealing remarkable chemical heterogeneity in the cells of the nervous system, they have virtually added a third dimension to the study of brains.

In very different ways, these techniques are central to the two journals reviewed here The *Journal of Chemical Neuroanatomy* has been established as a vehicle for publishing investigations using them; *Glia* is devoted to a field that owes much of its current vitality to the use of specific chemical markers for distinguishing glial cells from neurons, *in vivo* as well as *in vitro*. Both are well-produced journals, with good quality illustrations that will appeal to the dedicated followers of these subjects.

Glial cells have always been the poor relations in neuroscience. Lacking the excitement of propagated action potentials, they have often been regarded simply as stuffing between neurons. But in recent years support has come for those who have always advocated a subtle regulatory role for glial cells: they are now known to be involved in development, regeneration and perhaps maintenance of neurons; they regulate ion concentrations in the extracellular spaces of the nervous system; and they may even turn out to modulate conduction at nodes of Ranvier. They are also of clinical importance in demyelinating diseases and because of their propensity to form tumours.

These and other aspects are covered by papers in the early issues of *Glia,* which has most of the leading workers in the field on its editorial board and among its authors. Many of the contributions, which are mainly full-length research articles together with some stimulating invited reviews, are of general interest for neurobiologists. Because the workings of glial cells are clearly essential to our understanding of the nervous system, I hope the journal's title does not deter those who work on neurons from reading the work published there.

The brief of *Journal of Chemical Neuroanatomy* is wide: to publish papers giving insights into evolution, development, ageing and behaviour obtained with the large range of chemical neuroanatomy techniques now available. Despite the avowed intention of the editors to publish interdisciplinary articles that "increase the understanding of the nervous system in a comprehensive manner", the contents of the issues I have seen are limited largely to descriptive studies of localizaton of particular substances in a single system. Only the occasional paper meets the challenge of using techniques imaginatively in manipulative or comparative studies.

This journal thus seems likely to become a home for the vast amount of useful but rather dull descriptive work that is being produced with routine chemical neuroanatomy techniques. As long as enough people can be found to pay the rather high subscription rate, this will be a worthwhile service: because of the limited interest of each study and the need for lavish illustrations, such research is often difficult to publish elsewhere.

But to my mind, chemical neuroanatomy is one part of an integrated approach to the functional organization of the nervous system. Papers that achieve this aim should continue to be published in general neuroscience journals where they will attract far wider attention. □

Inside trading

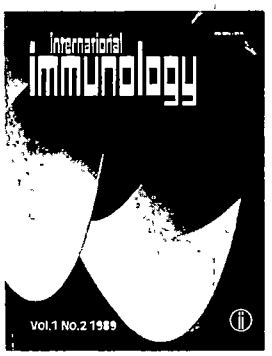
R.J.P. Williams

NMR In Biomedicine: An International Journal Devoted to the Development and Application of NMR Spectroscopy In Vivo. Editor-in-chief John R. Griffiths. *Heyden. 6/yr. UK and Europe £155, North America $263.*

THE subject of this journal is the study of biology and its possible application to medicine (I take it that is what biomedicine is) by non-invasive NMR methods. It is not intended to cover imaging by NMR, as far as I can tell, but only the study of chemical spectra in living systems.

The technique was developed many years ago now, but naturally enough in a

NMR *in* BIOMEDICINE



rough and ready way As the editor of the journal says in his introduction, "the field has undergone enormous expansion and great hopes and expectations rest on it". There is a sense of suspended judgement in this statement, which I believe is shared by many. Normally we expect an editor to state that a subject has been such an enormous success that a new outlet for papers was necessary. This journal, we are told, is required more so that "biological spectroscopists can speak to each other".

Most of us in our own corner of science also like to have a journal devoted to us — it saves us from looking around and it gives us an enhanced standing. There is a danger in this, however, and I feel that a newcomer journal would be foolishly managed if it fell into the trap. The danger is that it is irrelevant to anybody else except the specialist. *NMR in Biomedicine* needs to have some more general line. Let the main papers be as they are: about ^{13}C, ^{31}P, ^{1}H, ^{19}F NMR methodologies using all sorts of spectroscopic tricks. There is no harm in that. But let there be in as many issues as possible one review of what NMR used in this fashion has taught us about something (the liver, the brain, the citric acid cycle, for example) which we did not or could not know by other methods. Such reviews will reveal whether the hopes and expectations are being realized.

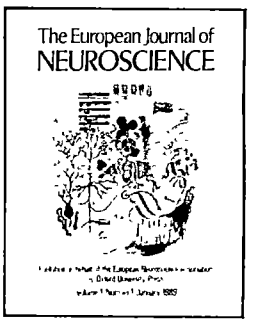
The editor states that NMR spectroscopy (of this kind) is at a cross-roads, and that his journal will lead it to fulfil its promise. The problem with cross-roads is that you inevitably arrive from one route but you have to know how to leave. The value of *NMR in Biomedicine* will be critically dependent on the direction taken. □

R J P Williams is in the Inorganic Chemistry Laboratory, University of Oxford, South Parks Road, Oxford OX1 3QR, UK.

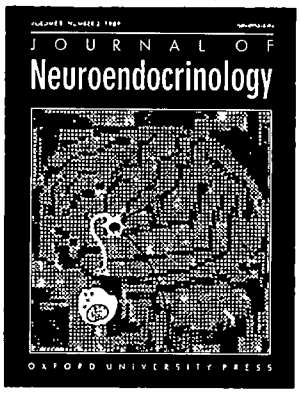
OXFORD JOURNALS

INTERNATIONAL IMMUNOLOGY

Editor-in-Chief: **Tomio Tada,** Department of Immunology, Faculty of Medicine, University of Tokyo, Tokyo, Japan 113



After one successful year of publication, **International Immunology** is now to be published monthly to accommodate the large and growing numbers of top-quality papers being accepted by its prestigious international editorial board.



Publishing a broad range of experimental and theoretical studies in molecular and cellular immunology conducted in laboratories throughout the world, the journal has no bias and no geographical barriers to publication.

THE EUROPEAN JOURNAL OF NEUROSCIENCE

Editor-in-Chief: **R. W. Guillery,** University of Oxford

This major new journal is an exciting initiative undertaken by the European Neuroscience Association. It is a Neuroscience journal of broad scope, ranging from the behavioral to the molecular, with a European focus but with a world-wide orientation. To this end, the editorial board represents all major areas of Neuroscience and has a broad international base. The journal contains influential articles and is set to become one of the leading journals in its field.

JOURNAL OF NEUROENDOCRINOLOGY

Editor-in-Chief: **Stafford Lightman,** Charing Cross and Westminster Medical School, London

Journal of Neuroendocrinology publishes timely papers dealing with the newest ideas, knowledge and technology in the neurosciences. In an extremely rapidly changing field, the **Journal of Neuroendocrinology** has the versatility to develop with the subject by being responsive to those changes. The journal covers molecular biology, cell biology and biochemical studies, developmental studies, molecular embryology and genetics, general systems, receptor and messenger systems, new technology for neuroendocrinology, behaviour, electrophysiology, ion channels etc., clinical and anatomical aspects.

THE JOURNAL OF NEUROSCIENCE

Editor-in-Chief: **Dale Purves**

'The journal combines papers of importance and depth with a very broad coverage . . . Each neuroscientist finds in it a selected sample of the best work in his own field, and also a sufficienctly broad coverage to allow him to maintain his knowledge of adjacent fields. The journal is now my major source of information about fields other than my own.''

— Vernon B. Mountcastle, M.D.
The Johns Hopkins University School of Medicine

Reader Service No.22

NEW JOURNALS FROM PERGAMO
LIFE AND SOCIAL

Life Sciences & Medicine

ANNUAL REVIEW OF ADDICTIONS RESEARCH AND TREATMENT

1990: Volume 1 (1 issue) (915)

A series of edited volumes designed both to summarize and put into historical and scientific perspective the developing field of alcohol and other drug studies. Will present, in their original form, some of the most important recent contributions to this field's expanding literature, with a focus of informed debate by commentators and reviewers who are each a leading authority. The broad domains of addictions research and intervention will be authoritatively surveyed, commented on, and updated in each volume.

BIOTECHNOLOGY EDUCATION

1990: Vol.2 (4 issues) (869)

Provides an enabling resource to teachers of biology, biochemistry and allied subjects who wish to introduce aspects of biotechnology into their existing courses. Articles give details of simple, tried and tested class experiments to illustrate practical applications.

CANCER COMMUNICATIONS

1990: Volume 2 (12 issues) (894)

The first international electronically published journal, designed to promote the rapid dissemination of significant observations. *Cancer Communications* publishes research in the areas of molecular biology, biochemistry, genetics, endocrinology, cell biology, biophysics, virology and immunology as well as studies on the mechanism of action of carcinogens and therapeutic agents.

CELLULAR SIGNALLING

1990: Volume 2 (6 issues) (851)

Publishes original papers covering all aspects of mechanisms, actions and structural components of cellular signalling systems.

HEC FORUM

An Interdisciplinary Journal on Hospitals' Ethical and Legal Issues

1990: Volume 2 (6 issues) (928)

The journal provides for the rapid communication of information on the ethical and legal issues confronting today's hospitals and health care providers. It aims to clarify and further the role of hospitals' ethics committees on a community, national and worldwide basis. Articles address both administrative and procedural concerns of HECs and attempt to establish policy for dealing with such substantive issues as medical and health care ethics, patients' rights and medical liability.

JOURNAL OF VESTIBULAR RESEARCH

Equilibrium and Orientation

1990: Volume 1 (4 issues) (936)

This new quarterly journal will publish experimental and observational studies, reviews and theoretical papers firmly based upon the current facts of vestibular science. Clinical papers are also featured.

THE JOURNAL OF JASTRO

The Official Journal of the Japanese Society for Therapeutic Radiology and Oncology

1990: Volume 2 (4 issues) (932)

A new journal for radiation oncologists performing studies focussing on clinical radiation therapy, combined with surgery and chemotherapy as well as hyperthermia, and on radiation physics and radiation biology. Papers are published either in Japanese with English abstracts, or in English.
Published by Pergamon Press Japan.

PROGRESS IN GROWTH FACTOR RESEARCH

1990: Volume 2 (4 issues) (875)

Features timely and authoritative reviews of current research and applications on growth factors and related regulatory peptides. The scope of the journal encompasses the structure and biological properties of growth factors, the structure and function of their receptors and signalling oncogenes, signal transduction pathways and effector systems, and regulation of gene expression.

QUALITY ASSURANCE IN HEALTH CARE

1990: Volume 2 (4 issues) (875)

Makes more widely available the results of quality assessment studies and quality assurance activities. The journal publishes papers in all disciplines related to the quality of health care, including health services research, health care evaluation, technology assessment, health economy, utilization review and nursing care research.

Social & Behavioural Sciences

CONTEMPORARY EUROPEAN AFFAIRS

1990: Volume 3 (4 issues) (913)

A new review of the major issues facing European society in the 1980s and 1990s. Each issue will be thematic: The first looks at *1992-and Afterwards*, with papers by many prominent figures including Jacques Delors and Bill Jordan. Volume 2 (4 issues) will deal with the following topics: the provision of health care in Europe; defence; European culture, and education.

IN THE SCIENCES

EUROPEAN JUDAISM
1990: Vol.23 (2 issues) (926)
A focal point and vehicle of experience for cross-currents of intellectual, cultural and spiritual influences which arise in Israel or the United States, and which can be creatively used by the Jewry of the new Europe. Leading Jewish writers, poets, scholars and intellectuals regularly contribute their work to the journal - over a wide range of subjects and from a variety of viewpoints. *European Judaism* also explores contemporary issues in the relationship between the Jewish community and the outside world, notably in terms of Jewish-Christian and Jewish-Muslim dialogue.

JOURNAL OF NEUROLINGUISTICS
1990: Volume 5 (4 issues) (866)
An international journal for the study of brain function in language behavior and experience.

LANGUAGE SCIENCES
A World Journal of the Sciences of Language
1990: Vol.12 (4 issues) (867)
Language Sciences is an interdisciplinary forum for the free exchange of ideas on the study of language.

Leading Scientific Journals Publishers

NEW IN TOXICOLOGY

INHALATION TOXICOLOGY

This new high quality journal provides the latest advances in all aspects of inhalation toxicology, to improve the understanding of the respiratory system in disease and health–for both humans and animals.
Editor: Donald E. Gardner, NSI Technology Services Corporation, Environmental Sciences, USA
ISSN 0895-8378, Vol 2, Institutional Rate: US$102 £59*

MOLECULAR TOXICOLOGY

Major emphasis is placed on *in vitro* studies concerned with genetic, regulatory or adaptive responses to chemical or physical agents at the molecular, cellular, or tissue level. **Molecular Toxicology** includes papers that contribute to our understanding of molecular mechanisms underlying environmentally induced changes in gene expression or addressing cellular functions that promote recovery or resistance to toxic chemicals or physical conditions.
Editor: Max Costa, New York University Medical Centre, USA
ISSN 0883-9492, Vol 3, Institutional Rate: US$99 £59*

NEW IN ARTIFICIAL INTELLIGENCE

JOURNAL OF EXPERIMENTAL & THEORETICAL ARTIFICIAL INTELLGENCE

Journal of Experimental & Theoretical Artificial Intelligence aims to advance scientific research in artificial intelligence by providing a public forum for the presentation, evaluation and criticism of research results, the discussion of methodological issues, and the communication of positions, preliminary findings and research directions.
Editors: Eric Dietrich, State University of New York, **Chris Fields**, New Mexico State University, USA
ISSN 0952-813X, Vol 2, Institutional Rate: US$129 £72*

NEW IN THE ENVIRONMENT

SOCIETY AND NATURAL RESOURCES

This new journal focuses on biological and physical changes resulting from acid rain, biological and genetic diversity in worldwide agriculture; and water resource degradation.
Editor: Donald R. Field, University of Wisconsin, USA
ISSN 0894-1920, Vol 3, Institutional Rate: US$79 £46*

ARID SOIL RESEARCH AND REHABILITATION

Arid Soil Research and Rehabilitation provides a useful source for articles on fundamental basic and applied aspects of arid and semiarid soils. Subjects covered in the journal include: soil biology in non-irrigated soils, arid land rehabilitation and arid soil biotechnology.
Editor: J. Skujins, Utah State University, USA
ISSN 0890-3069, Vol 4, Institutional Rate: US$90 £51*

ADVANCED POWDER TECHNOLOGY

Editor-in-Chief: Y. Morikawa

The aim of ADVANCED POWDER TECHNOLOGY is to meet the demand for an international journal integrating all aspects of research on powder engineering and technology. ADVANCED POWDER TECHNOLOGY reports on research in various areas of powder technology such as particle characterisation, mechanical powder properties, storage, conveying, communition, classification, agglomeration, mixing and kneading, dispersion, reactor design, dust, separation, filtration.

ISSN 0921-8831
1990: Volume 2 in 4 issues *DM 360*

ADVANCED COMPOSITE MATERIALS

Editor-in-Chief: H. Hojo

ADVANCED COMPOSITE MATERIALS, a new quarterly publication of the Japan Society for Composite Materials, provides an international forum for researchers, manufacturers and designers who are working in the field of composite materials and their structures. Issues will contain articles on all aspects of current scientific and technological progress in this interdisciplinary field.

ISSN 0924-3046
1990: Volume 1 in 4 issues *DM 360*

ARTIFICIAL ORGANS TODAY

Editor-in-Chief: T. Agishi

The aim of ARTIFICIAL ORGANS TODAY is to introduce not only the latest results from research but also new clinical applications in the field of artificial organs from Japan and other countries to a world-wide readership.

ISSN 0924-3054
1990: Volume 1 in 4 issues *DM 360*

JOURNAL OF BIOMATERIALS SCIENCE, Polymer Edition

Editors: C.H. Bamford, S.L. Cooper and T. Tsuruta

This new quarterly journal will publish fundamental research on the mechanisms of interaction between biomaterials and living organisms, with attention being focused at the molecular and cellular levels. The JOURNAL OF BIOMATERIALS SCIENCE, Polymer Edition, will deal with polymers, synthetic and natural, as the most versatile biomaterials, having wide-ranging applications in the medical, biomedical and biological fields.

ISSN 0920-5063
1990: Volume 1 in 4 issues *DM 360*

FRONTIERS OF MEDICAL AND BIOLOGICAL ENGINEERING

Editor: M. Saito

Papers in FRONTIERS OF MEDICAL AND BIOLOGICAL ENGINEERING are either revised and translated articles from Japanese journals or are originally submitted to the new journal. By accepting both purely scientific papers giving new fundamental information and articles containing technical, industrial and/or clinical data, the journal covers the field of medical and biological engineering in its broadest sense.

ECOLOGICAL ECONOMICS

Journal of the International Society for Ecological Economics (ISEE)

Editor-in-Chief: Robert Costanza, Solomons, MD, U.S.A.

Associate Editors:
Herman Daly. Washington, DC, U.S.A.
Ann-Mari Jansson, Stockholm, Sweden
David Pearce, London, U.K.

Aims and Scope:
Concerned with extending and integrating the study and management of "nature's household" (ecology) and "mankind's household" (economics). This integration is necessary because conceptual and professional isolation have led to economic and environmental policies which are mutually destructive rather than reinforcing in the long term.

The journal is transdisciplinary in spirit and methodologically open. Specific research areas covered include: valuation of natural resources, sustainable agriculture and development, ecologically integrated technology, integrated ecologic--economic modelling at scales from local to regional to global, implications of thermodynamics for economics and ecology, renewable resource management and conservation, critical assessments of the basic assumptions underlying current economic and ecological paradigms and the implications of alternative assumptions, economic and ecological consequences of genetically engineered organisms, and gene pool inventory and management.

Forthcoming Papers:
The convergence of neo-Ricardian and embodied energy theories of value and price *(D.H. Judson)* • Ecological economic modeling in a pluralistic, participatory society *(J.A. Maxwell and A. Randall)* • Okoboji experiment: comparing non-market valuation techniques in an unusually well-defined market for water quality *(R.C. d'Arge and J.F. Shogren)* • On the use of ecological prices and system-wide indicators derived therefrom to quantify man's impact on the ecosystem *(S. Amir)* • On the ideological foundations of environmental policy *(D.A. Underwood and P.G. King)* • Can the world be saved? *(G. Speth)* • Valuation and management of wetland ecosystems *(R. Constanza, S.C. Farber and J. Maxwell)* • Economy-environment interactions in the long-run: a neo-Austrian approach *(M. Faber, J. Proops, M. Ruth, and P. Michaelis)* • Three dilemmas of environmental accounting *(R.B. Norgaard)*

GLOBAL AND PLANETARY CHANGE

Daughter-journal to Palaeogeography, Palaeoclimatology, Palaeoecology

Editors:
E. Barron, University Park, PA, USA
S. Cloetingh, Amsterdam, The Netherlands
A. Henderson-Sellers, North Ryde, N.S.W., Australia
D. Liverman, Madison, WI, USA
M. Meybeck, Paris, France
B. Moore, Durham, NH, USA
P.A. Pirazzoli, Paris, France

Aims and Scope:
Provides a much-needed multidisciplinary view of the causes, processes and limits of variability in planetary change, focusing on the record of change in earth history and the analysis of recent and prediction of future changes. Topics include, but are not limited to, changes in the chemical composition of the oceans and atmosphere, climate change, sea level variations, human geography, global geophysics/tectonics, global ecology and biogeography.

Subscribers to *Palaeogeography, Climatology, Ecology* automatically receive *Global and Planetary Change*, which can also be subscribed to independently.

Recently Published and Forthcoming Papers:
• The hydrologic cycle: a major variable during Earth history *(E.J. Barron, W.W. Hay and S. Thompson)* • North American total cloud amount variations this century *(A. Henderson-Sellers)* • Modelling the ocean climate for the early Archaean *(B. Henderson-Sellers and A. Henderson-Sellers)* • Phanerozoic O_2 variation, fire, and terrestrial ecology *(J.M. Robinson)* • Global climatic changes during the Devonian-Mississippian: Stable isotope biogeochemistry of brachiopods *(U. Brand)* • The quality of rivers: From pristine stage to global pollution *(M. Meybeck and R. Helmer)* • Carbon redox and climate control through Earth history: A speculative reconstruction *(T.R. Worsley and R.D. Nance)* • Present and near-future global sea-level changes *(P.A. Pirazzoli)*

JOURNALS FROM WILEY

NEW

Permafrost and Periglacial Processes

Editor-in-Chief: H.M. FRENCH, Departments of Geology and Geography, University of Ottawa, Ontario K1N 6N5, Canada

Associate Editors: E.A. KOSTER, University of Utrecht, The Netherlands, and A. PISSART, University of Liege, Belgium

Permafrost and Periglacial Processes is an international journal dedicated to the rapid publication of scientific and technical papers concerned with earth surface cryogenic processes, landforms and sediments present in a variety of (Sub) Artic, Antarctic and High Mountain environments. It provides an efficient vehicle of communication amongst those with an interest in the cold, non-glacial geosciences. The focus is on (1) original research based on geomorphological, hydrological, sedimentological, geotechnical and engineering aspects of these areas and (2) original research carried out upon relict features where the objective has been to reconstruct the nature of the processes and/or palaeoenvironments which gave rise to these features, as opposed to purely stratigraphical considerations. The journal also publishes short communications, reviews, discussions and book reviews. The high scientific standard, interdisplinary character and worldwide representation of *Permafrost and Penglacial Processes* are maintained by regional editorial support and a rigorous refereeing system.

Volume 1 (1990) 4 issues UK £75.00 Elsewhere US$135.00

Land Degradation & Rehabilitation

Managing Editor: C.J. BARROW, Centre for Development Studies, University College of Swansea, Singleton Park, Swansea SA2 8PP, Wales, UK

Land Degradation & Rehabilitation is an international journal which seeks to promote rational study of the recognition, monitoring, control and rehabilitation of degradation in terrestrial environments Identifying the processes and causes of degradation and knowing techniques for control and rehabilitation are vital, but are of limited value unless the problem can be managed. The Journal will therefore, in addition to the aforementioned subjects publish papers on political, economic, social and historical aspects, forecasts of trends, case-studies and management of land degradation.

Land degradation is a problem in rich and poor, capitalist and communist nations, rural and urban areas. It is a major threat to development and quite possibly to the survival of mankind and other organisms. A major challenge in the coming decades is to learn how interactions between development and environment can be better managed to increase prospects for ecologically and socially sustainable improvements to human well-being.

In addition to original research papers, regional and thematic reviews, both invited and submitted, will be included, as will case-studies, short communications and book reviews. The members of the Editorial Board are drawn from a comprehensive range of relevant disciplines and nationalities. Together with a strict refereeing procedure this will ensure *Land Degradation & Rehabilitation* achieves a high standard and maintains an interdisciplinary and international content.

Microbial Ecology in Health and Disease

Editors: S.P. BORRIELLO, Clinical Research Centre, Harrow, UK and C. RUSSELL, University of Manchester, Manchester, UK

The aim of this new international journal is to draw together research on different human microbial eco-systems, and to increase our understanding of their role in health and disease. This research has received new impetus in recent years as it has become clearer what part is played by the normal stable, microbial flora in preventing infection, especially opportunist infection, and related to this, the potentially deleterious effects of the use of antibiotics.

The identification and distribution of the organisms that make up a 'normal' flora and the analysis of the conditions which govern their presence and survival is difficult and complex. Already the medical implications of this work are apparent: as part of the prevention or treatment of microbial disease, attempts have been made to recreate 'normal' flora in the gut, oral and nasal cavities, skin, throat and vagina. The research reported in this journal will also be of value to those working in related areas such as veterinary science and animal husbandry.

The new journal will consider original research papers, and commission occasional review articles on the microbial flora of the mouth, skin, respiratory, gastro-intestinal and genito-urinary tracts.

Neuroscience Research Communications

Editor: W.H. GISPEN, PO Box 85174, 3508 AD Utrecht, The Netherlands. Tel (0) 30-532995

Associate Editors: A.R. COOLS, Nijmegen, The Netherlands, and F.H. LOPES DA SILVA, Amsterdam, The Netherlands

Neuroscience Research Communications publishes important, original contributions to the neurosciences. The journal is international and multidisciplinary and welcomes papers in all areas of the neurosciences. It comprises short papers, selected mini-reviews and timely comments by leading authorities on current topics. Papers are quickly and fully reviewed by independent leading experts in the various disciplines and only high quality papers are accepted.

Cambridge Journals

To meet the growing needs of today's scientists, Cambridge University Press brings you five new science journals in 1990. To order, or for further information and a sample copy fill in the coupon and return it to the address below

Journal of Functional Programming

Editors:
R J. M HUGHES, *Department of Computing Science, Glasgow*
P. L WADLER, *Department of Computing Science, Glasgow*
P. HUDAK, *Department of Computer Science, Yale University*
H. BARENDREGT, *Katholieke Universiteit Nijmegen*

Journal of Functional Programming is the first journal to be devoted to this important area of computer science. It covers new languages and extensions, reasoning, proof and program synthesis, implementation techniques, type theory, parallelism, and applications. The journal is of interest to computer scientists, engineers working in parallelism, and mathematicians working in theoretical science.

Volume 1 in 1990: two parts

Subscription
£60 for UK subscribers, £65/$110 elsewhere; £40/$70 for IFIP members

ISSN 0956-7968

Psychological Science

Editor:
WILLIAM K. ESTES, *Department of Psychology, Harvard University*
Published for the American Psychological Society

This publication is being launched as the flagship journal of the American Psychological Society and is the forum for research, theory and application in psychology and the closely related behavioural, cognitive, neural and social sciences. Unlike most research journals, *Psychological Science* encourages articles of general theoretical significance or of broad interest across specialities, written to be intelligible to a wide range of readers Topics in the first volume include language in scientific psychology and similarities involving attributes and relations.

Volume 1 in 1990: January, March, May, July, September and November

Subscription
£65/$100 for institutions; £30/$50 for individuals

ISSN 0956-7976

Arabic Sciences and Philosophy: A Historical Journal

Executive Editors:
BASIM MUSALLAM, *Centre of Middle Eastern Studies, University of Cambridge*
ROSHDI RASHED, *Centre d'Histoire des Sciences et de la Philosophie Arabes, Centre National de la Recherche Scientifique*
JEAN JOLIVET, *L'Ecole Pratique des Hautes Etudes, Paris*
MUHSIN MAHDI, *Department of Eastern Languages and Literature, Harvard University*

This international journal is devoted to the history of the Arabic sciences, mathematics and philosophy in the world of Islam between the eighth and the eighteenth centuries in a cross-cultural context *Arabic Sciences and Philosophy* casts new light on the growth of these disciplines as well as on the social and ideological context in which this growth took place Articles are published in English, French or German with abstracts in all three languages.

Volume 1 in 1990 March and September

Subscription
£48/$75 for institutions, £28/$39 for individuals

ISSN 0957-4239

European Journal of Applied Mathematics

Editor-in-Chief:
JOHN OCKENDON, *Mathematical Institute, University of Oxford*

EJAM is a new journal for original work in areas of mathematics in which an understanding of the application requires the use of new and interesting mathematical ideas. The advent of powerful user-friendly computer codes in science and industry has increasingly led research workers to pose their problems in mathematical terms. Such activity frequently leads to a need for new mathematical analysis at a high level. EJAM will focus on this growing area of mathematics inspired by real world applications, and at the same time it will foster the development of theoretical methods with broad areas of applicability.

Volume 1 in 1990: March, June, September and December

Subscription
£75 for UK subscribers; £80/$150 elsewhere, members of ECMI should write for special rates

ISSN 0956-7925

Polar and Glaciological Abstracts

Editor:
WILLIAM MILLS, *Scott Polar Research Institute, Cambridge*

Polar and Glaciological Abstracts is the first specialist abstracting publication to offer comprehensive coverage of the world's polar regions Produced by the library of the Scott Polar Research Institute, it provides comprehensive and convenient access to the rapidly growing research and scholarship of all relevant disciplines. It scans over 900 series, plus relevant books, reports and theses. Each issue contains author, subject and geographic indexes. The indexes are cumulated annually.

Volume 1 in 1990: January, April, July and October

Subscription
£40/$75 for institutions; £30/$55 for individuals

ISSN 0957-5073

Cambridge Journals

PHYSICA C - Superconductivity

Since June 1, 1989, Physica C appears **SEMIMONTHLY** instead of monthly. This means an even more rapid publication of full-text papers and a guarantee of publication time within 6 weeks for papers that are immediately approved by the referees. Please note that the average publication time will be somewhat longer, as up to now 48% of papers submitted needed revision.

The semimonthly publication schedule will be as follows:

July	vol. 159 no. 4	October	vol. 160 nos. 5/6
	vol. 159 no. 5		vol. 161 no. 1
August	vol. 159 no. 6	November	vol. 161 no. 2
	vol. 160 nos. 1/2		vol. 161 no. 3
September	ol. 160 no. 3	December	vol. 161 no. 4
	vol. 160 no. 4		vol. 161 nos. 5/6

(Proceedings of HTSCM^{2}S, Stanford, USA is part of the 1990 publication schedule.)

Combined issues will be published when necessary and the schedule may therefore deviate from the above.

For further information and/or a free inspection copy please contact:

NORTH-HOLLAND, PO Box 103, 1000 AC Amsterdam, The Netherlands.

Circle number 15 on Reader Service Card

VASCULAR MEDICINE REVIEW

Diseases of the vasculature represent the major cause of morbidity and mortality in the western world and impinge upon all branches of medicine.

This new journal, publishing in 1990, will provide an up-to-date, authoritative reference source which aims to stimulate multidisciplinary interest and approaches appropriate to the advancement of knowledge and clinical practice.

Subject areas reviewed include developments in vascular biology and biochemistry, pathophysiological mechanisms, epidemiology, measurement and imaging of the vasculature and vascular pharmacology, as well as evaluation of new medical and surgical therapies.

Vascular Medicine Review will appeal to all those engaged in the study and/or care of patients with vascular disease.

FETAL MEDICINE REVIEW

First published in 1989, this journal is dedicated to the advancement of knowledge and clinical practice in this expanding specialty.

In each issue an impressive group of international contributors brings together the substantial amount of new information accumulating in this field. Rapid publication, making use of new technology, and a deliberate preference for young authors currently active in research in the specialty ensures that this journal has immediate relevance to contemporary clinical practice.

Subject areas reviewed include developments in counselling, diagnosis, fetal pathophysiology, imaging, immunology and principles of management and therapy (both maternal and fetal).

Fetal Medicine Review will appeal to all engaged in the care of pregnant women and neonates.

For further information on submitting papers, requesting sample copies or subscription rates, please contact the Journals Department at the address below.

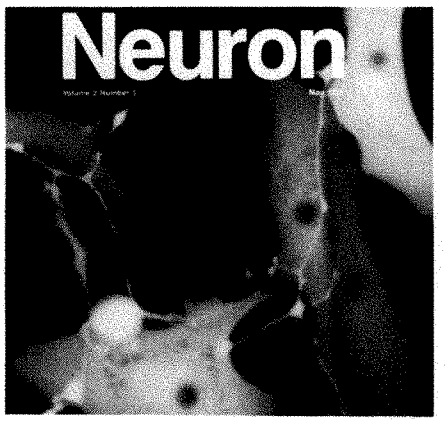
Cell sister

Michael R. Hanley



Neuron. Editors Zach W. Hall, A. J. Hudspeth and Louis F. Reichardt. *Cell Press, 50 Church Street, Cambridge, Massachusetts 02138. 12/yr. US $210, Europe $260, elsewhere $235 (institutional); US $94, Europe $134, elsewhere $114 (personal).*

ONE of the success stories in scientific publishing has been the emergence of the biological-science journal, *Cell*. Largely, if not exclusively, the vision of one individual, Benjamin Lewin, *Cell* has become the pre-eminent forum for full-length research papers in molecular and cell biology. It is not surprising, therefore, that the publisher has set off after new challenges. The result is *Neuron*, and its aim is to be *the* journal in neuroscience.

Neuron publishes a combination of commissioned reviews and full-length research manuscripts. Production standards are first-rate, with high-quality reproduction of gels, photomicrographs and autoradiographs. The editorial office handles submitted manuscripts efficiently, and the turnaround time from submission to publication is often within the two-to-three months ideal achieved by *Cell* and *EMBO Journal*.

To date, the original papers have been good, but not distinguished. This may, in part, be due to the inevitable problem for specialist journals of drawing the best papers away from the broad-circulation, general-interest journals. Indeed, it remains to be seen what sort of neuroscience will be published by *Cell* in the future. For example, much of the recent research on the developmental genetics of *Drosophila* eye has widespread interest for biologists, and would perhaps be blunted in its impact if it were to appear in a parochial neuroscience setting. The generality of problems in signal transduction, cell adhesion, pattern formation, transcriptional regulation of gene expression and growth control will mean that a journal such as *Neuron* will find it progressively harder to define what belongs to its pages. But it must be said that the editors have shown a forward-looking and insightful flexibility in recognizing that points of fundamental interest to the neuroscientist may be established in some surprising experimental systems.

I am particularly impressed with the commissioned reviews which have emerged, to my mind, as the journal's clearest strength. The topics that have been covered include creation of nerve-cell lines by immortalizing gene transfer, neural-crest cell lineage, retinoids and morphogenesis, long-term potentiation, regulation of growth cones and mechanisms of trophic factors. These are some of the most exciting areas of neuroscience, and are subjects that profit from critical consideration of the larger biological context. In many cases, the articles break sufficient new ground to prompt the thought

that they are a new kind of primary research publication, one devoted to ideas rather than experimental results.

These successes show the influence of a tough and effective editorial board. As with *Cell*, the editors and their board are drawn from the ranks of the innovative and the progressive, and the board is not top heavy with the identikit panel of old fogeys. This may mean that *Neuron* will be prepared to take some risks, and it will be interesting to see if its early promise of publishing provocative and stimulating papers is fulfilled.

Inevitably, *Neuron* will be judged against competitors such as *Journal of Neuroscience*, *Neuroscience* or *European Journal of Neuroscience*. Unlike the others, *Neuron* is essential for any library in the biological sciences. It is also one of the few journals for which a good case can be made for individual subscription. It is realistically (though certainly not altruistically) priced, but the main reason for recommending a personal subscription is not affordability. Rather it is that *Neuron*, like *Cell*, appears to be bound primarily by static electricity. Whoever conceived the binding of these journals has succeeded in making them disintegrate upon repeated photocopying. This trait of the Cell Press journals may please the publishers but annoys the scientific consumer no end. It should not be impossible to invest in a little glue. □

Michael Hanley is in the MRC Molecular Neurobiology Unit, Hills Road, Cambridge CB2 2QH, UK.

Sight lines

John Cronly-Dillon

Visual Neuroscience: An International Journal for Empirical and Theoretical Research. Editor Katherine V. Fite. *Cambridge University Press. 12/yr. UK and elsewhere £182, North America $280 (institutional); UK and elsewhere £84, North America $120 (personal).*

NEW journals on vision appear with almost predictable regularity. They differ little from one another in style or format, which encourages the impression that their main *raison d'être* is to provide further venues for publications that help the researcher in his grant applications.

Having seen the first few issues of the *Journal of Visual Neuroscience*, I am reassured that any reservations of that sort were, in this case, ill founded. In the first issue, the editor states that "the primary goal of *Visual Neuroscience* is to bring together in one journal a broad range of excellent studies that represent the diversity and originality of contemporary research and theory dealing with the neural basis of vision". On the face of it, this seems like a *carte blanche* invitation to authors to submit a Pandora's box of contributions, that is, until one examines the list of research areas covered by the journal — comparative visual-system studies, organization and function; developmental processes and patterns, photoreceptors and transduction; retinal anatomy, physiology, neurochemistry; subcortical visual pathways, visuomotor functions; thalamo-cortical pathways, visual cortex, perceptual mechanisms; and theoretical computational models.

This is a well-balanced selection of topics, which together probably represent the main thrust of research in visual neuroscience. As a place in which studies of them are brought together, the journal is likely to be extremely useful to active researchers who wish to keep their fingers on the pulse of a wide variety of related fields while dispensing a minimum of effort. In this respect it seems to me that the journal's appeal could be further improved by the periodic inclusion of an invited review article on a topic relating to one of the designated subject areas, and perhaps a regular editorial reflecting on notable developments in visual neuroscience.

A challenge for any new journal, even one that is well planned, is whether it is able to meet its declared intentions by attracting contributions which, in terms of quality, content and range of topics, fulfil its aspirations. Again, I was impressed on all three counts. If this standard can be maintained *Visual Neuroscience* will, I suspect, find a well-earned place on the shelf of every research worker with a serious interest in the subject. □

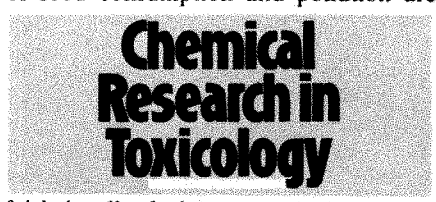
John Cronly-Dillon is in the Department of Optometry and Vision Sciences, University of Manchester Institute of Science and Technology, Manchester M60 1QD, UK.

From East to West

David Clark

Chemical Research in Toxicology. Editor Lawrence J. Marnett. *American Chemical Society. 6/yr. US $269, Europe $280, elsewhere $283 (institutional); US $46, Europe $57, elsewhere $60 (personal).*
Biomedical and Environmental Sciences. Editors Frederick Coulston and Chen Chunming. *Academic. 4/yr. UK £77, North America $100, elsewhere $112, (institutional); UK £40, North America $60 (personal).*

By their very nature, toxicology and environmental science are wide-ranging subjects. They extend to all aspects of our well-being and relationship with our surroundings, and draw on virtually all scientific disciplines.



Both are fertile fields and a great attraction to publishers, who can opt for one of two strategies for their journals — the specialist or the generalist. Provided that a specialized journal finds a niche with few established rivals, it stands a better chance of being bought, read and quoted widely than a general one which has to face chillier winds of competition for quality papers. One of the journals reviewed here is specialized, the other general (although with a unique difference).

Chemical Research in Toxicology publishes papers on modern techniques of chemical analysis applied to toxicological problems, the identification of novel toxic agents and reactive intermediates, and the metabolism of toxic agents. An invited review or perspective on some aspect of chemical toxicology appears in each issue. As would be expected of a journal of the American Chemical Society, it has been able to sustain publication of quality research papers, particularly in chemical analysis and reactive intermediates. The invited reviews and perspectives have been particularly well chosen and are of high quality.

The editors have emphasized their commitment to speed of review and publication, and so far have done very well in this respect. Only time will tell, however, if this can be maintained after the honeymoon is over. Now that *Chemical Research in Toxicology* has clearly established itself in North America, more international contributors would be welcome to ensure the journal a wider area of authority.

Biomedical and Environmental Sciences is a completely different animal and difficult to judge by normal standards. Its stated scope is very wide and embraces the biological and toxic effects of environmental pollutants on human beings and other forms of life, with special emphasis on scientific findings in China. Indeed the editorial board state that this "is not just another journal, but a forthright decision to help overcome the Chinese Scientists' years of frustration and underdevelopment".

To this end the editors undertake to help with their contributors' English, which they have done to such good effect that the Chinese papers are indistinguishable from those written by native English speakers. The scientific quality of the articles is variable, however, ranging from standard reviews by European or American authors, such as Zbinden on animal alternatives and Munroe on risk assessment of carcinogens, to specific articles on Chinese epidemiology. Interestingly, the editors point out that because the Chinese are generally less mobile and their patterns of food consumption and pollution are

fairly localized, there are valuable opportunities for epidemiology studies without some of the usual confounding factors.

The flow of general review articles by Westerners is likely to slow during the coming years and *Biomedical and Environmental Sciences* will then stand or fall on the quality and relevance of the Chinese contributions. One wishes a journal with the aim of opening the door to Chinese toxicology well. We must hope that recent political events in China do not close the door before the journal can make its mark. □

David Clark is the Head of Toxicology of Unilever Research, Unilever House, Blackfriars, London EC4P 4BQ, UK.

Linking up

Ian Croall

Neural Networks. Co-editors-in-chief Shun-Ichi Amari, Stephen Grossberg and Teuvo Kohonen. *Pergamon. 6/yr. DM370.*

The arrival of this journal, described as "The Official Journal of the International Neural Network Society", accompanies the commercial emergence of neural networks as a defined topic after a long period of gestation.

The origins of the subject lie in attempts to understand the workings of the brain at all levels — biological, chemical, psychological and so on. Now there appear to be two extremes in approach. At one end there are those concerned with using the ideas inherent in the work to produce more powerful computer systems without much regard for biological fidelity. At the other we have people whose prime objective is much the same as the original one, that is the construction of models which help to extend our knowledge and understanding of brain functions.

Neural Networks intends to cover the whole of this spectrum. The first two issues contain excellent introductory articles from two of the gurus of the subject, Kohonen and Grossberg, though the connectionist point of view, reflected by Rumelhart and McClelland in their book *Parallel Distributed Processing*, is not represented. The contributions, in the first issues are of a high standard and do indeed cover the subject area well, which is most important as many traditional disciplines are involved and papers dealing with them have hitherto appeared in a wide variety of often obscure journals.

Theoretical papers come from people with a variety of backgrounds, and provide a challenge to the reader with their divergent approaches to the subject. There is rather less information on applications and comparisons with 'conventional' methods, and the emphasis is on the whole away from the biological.

Throughout, the standard of production is well up to that expected of Pergamon Press. At its present size and quality, *Neural Networks* is good value. □

BBA 1,000

One of the first journals to be published by Elsevier was *Biochimica et Biophysica Acta* (BBA), which was launched in 1947. This month, the journal celebrates the appearance of its 1,000th volume.

The 1,000th volume is given over to the republication of notable papers in BBA. Accompanying them are commentaries by one or some of the original authors, setting the particular scientific finding in context and reflecting on developments since then.

Among the contributors are E. Chargaff, who writes about the paper "Studies on the Structure of Ribonucleic Acids", published in 1951; J. Brachet ("Proteines de Structure de Szent-Györgyi et Thymonucléohistone", 1947); A. Kornberg ("Enzymes Synthesis of Deoxyribonucleic Acid", 1956); S. Ochoa ("Enzymes of Fatty Acid Metabolism", 1953); C. de Duve ("Intracellular Localization of Catalase and of Some Oxidases in Rat Liver", 1960); and M. Calvin ("Intermediates in the Photosynthetic Cycle", 1956).

Over the fields

Tom Blundell

Journal of Molecular Recognition. Editor-in-chief Irwin M Chaiken *Heyden 6/yr UK and Europe £149, North America $253*

MOLECULAR recognition mediates information storage, replication and transfer in all biological systems. What then is the specific role of the *Journal of Molecular Recognition* when the subject pervades all areas of biology?

According to the information for authors, the journal is a "multidisciplinary publication devoted to research on the basic principles, characterisation and application of specific interactions in biology, biotechnology and medicine". The journal certainly meets this broad remit. It has published interesting articles by distinguished authors on immunomagnetic separation technology, the insulin receptor, cognitive features in epitopes, mimetics of ß-turns, the self-assembly of neurohypophyseal hormone precursors and binding sites for bleomycin on DNA. All involve molecular interactions and recognition. But in spite of the individual excellence of the articles, the journal has yet to identify a niche in the fast-expanding fields of molecular and cell biology. The lack of a 'self-assembling and easily recognized' group of authors appears to be reflected in the very long period — June 1988 to April 1989 — between the third and fourth issues of Vol. 1.

Molecular recognition has been the topic of research in biophysical circles for many years. Fred Richards, David Phillips, Max Perutz and many others identified the importance of weak interactions involving the complementarity of surfaces, hydrogen bonds and ionic interactions in proteins two decades ago and set the scene for the theoretical analysis and quantification that has occurred since. Why then is it only in the past few years that government organizations and publishers have chanced upon the term 'molecular recognition' and exploited it with investment in new research initiatives and new journals?

The reason, in part, is the recruitment of large numbers of chemists and biologists into molecular and cell biology as a consequence of the success of recombinant DNA methodology and biophysical approaches to the three-dimensional structure of macromolecules. Much of the scientific community is new to the area even though the concepts are old. However, it is also a consequence of the emphasis on planning and themes that has recently characterized science policy even under the governments of free marketeers such as Margaret Thatcher and Ronald Reagan. According to John Ziman, 'science in a steady state' requires more management and selection, the natural trend of science is to expand exponentially, as de Solla Price pointed out in 1963, but this is no longer possible. The new planning policies appear to have led to a proliferation of labels such as molecular recognition, biotransformations and protein engineering for activities that already have a history.

The existence of the *Journal of Molecular Recognition* thus reflects changes in the nature of scientific policy making, and also the existence of new multidisciplinary communities. The challenge for the journal is to draw out of each topic the aspects of molecular recognition which may be relevant and of interest to the wider community in this diffuse area of science. Emphasis may be on technological advances which underpin the science, or on experimental or theoretical approaches that extend our understanding of the general principles of molecular

recognition. On the basis of the first four issues, the journal has still some way to go before it can meet these ambitious objectives that are described by the editor but not widely manifested in the material published. □

Ill treatment

Malcolm Rowland

Advanced Drug Delivery Reviews. Editors-in-chief R. L Juliano, G Poste and E Tomlinson. *Elsevier. 6/yr Dfl.888*
Journal of Drug Development. Editor A. D. S Caldwell. *Gardiner–Caldwell, The Old Ribbon Mill, Pitt Street, Macclesfield, Cheshire SK11 7PT, UK 4/yr. £85, $140.*

THE dramatic discoveries arising out of cellular and molecular biology portend well for the emergence of new classes of therapeutic agents for the treatment of diseases that plague man, other animals and plants. As the editors of *Advanced Drug Delivery Reviews* correctly stress, however, these discoveries will not translate into effective treatments unless they

are matched by new strategies to achieve optimal delivery of the agents to their target sites. Innumerable promising entities have failed to reach the marketplace either, for example, because of poor absorption from sites of administration, non-specific tissue distribution with unwanted toxicity, or because of failure to penetrate the target site.

The editors of the journal have recognized that the solution to problems in drug delivery requires an interdisciplinary approach and have rightly sought reviews that cover a wide range of areas in chemistry, biology and medicine. Emphasis has been on the newer, more advanced approaches, with a strong trend to date towards papers dealing with the placement of drug delivery in a biological context — a definite plus in my opinion.

So far all of the reviews have been of an exceptionally high technical quality, being critical, timely, thorough and well referenced. Many make absorbing reading. This is perhaps not surprising as many of the initial contributions have been written by members of a well-chosen editorial board. The technical standard is matched by a correspondingly high quality of presentation.

In addition to the established journals in the pharmaceutical sciences, several others have appeared over the past few years which would claim to cover one or more aspects of drug delivery. Among them are *Pharmaceutical Research*, *CRC Critical Reviews of Therapeutic Drug Carrier Systems* and *Cancer Drug Delivery*. Nonetheless, as long as *Advanced Drug Delivery Reviews* maintains its current quality and breadth, it has nothing to fear. It is an invaluable addition to the library of any serious investigator in drug delivery.

Drug development, from creation or discovery of an active substance, to its addition to the therapeutic armament of the prescribing physician, is a fascinatingly complex, risky but rewarding business. The high standing that society places on drug development is attested by the recent award of a Nobel prize to Sir Douglas Black for his role in the successful development of two important drugs, propranolol and cimetidine. So, when a new journal with the title *Journal of Drug Development* appears it is a matter of some interest. When, however, in its first number the editor states, albeit with commendable honesty, that he is unsure as to the scope and place of the journal,

one can be excused for being a trifle concerned. This concern is intensified by further editorial comments and by the contents of subsequent issues.

The editor claims to offer rapid publication (which is strange for a quarterly publication) particularly of research from within the pharmaceutical industry. But there is no difficulty in publishing good research, whatever its origin, and rapidly if necessary. The contents of the journal vary from chemical analysis to (primarily) the results of clinical investigations. The articles are often short and are generally of a mediocre quality. The better ones are often reviews.

The journal has two interesting features — each issue includes a free-ranging guest editorial, and referees are invited to append comments to the respective article. The quality of presentation is excellent and the annual subscription rates are average, but the page charges seem rather excessive given the small pages and relatively large type-size. One wonders who the target contributor can be when quotations are given for up to 50,000 offprints. Overall, there is little to commend *Journal of Drug Development* over the numerous and better journals that currently exist. □

Malcolm Rowland is in the Department of Pharmacy, University of Manchester, Coupland 3 Building, Oxford Road, Manchester M13 9PL, UK.

Flying the flag

P. F. R. Little

Genomics: International Journal of Gene Mapping and Nucleotide Sequencing Emphasizing Analyses of the Human and Other Complex Genomes. Editors-in-chief Victor A. McKusick and Frank H. Ruddle. *Academic. 8/yr. UK £206, North America $282, elsewhere $309 (institutional); UK £78, North America $100, elsewhere $117 (personal).*

GENE mapping was once the pursuit of a small group of enthusiasts, powered by a strong vision of what might be possible. Then recombinant-DNA technology blasted the field into a forefront of biology, the human genome initiative perhaps being its most visible feature. *Genomics* was set up in 1987 in response to this surge of activity, to provide a specialist vehicle for publication of gene mapping and nucleotide sequences.

On looking at any issue of the journal, it is immediately apparent that standards in gene mapping are very different from those in virtually all other areas of molecular genetics — not worse (or better), just different. For example, it is inconceivable to me that a report showing that a gene was *not* located on a specific chromosome or region would constitute a publishable finding in mouse or *Drosophila* research. Nevertheless such reports, as well as the normal gene/sequence localization papers, appear in *Genomics*. The reasons are not hard to appreciate — map location is definable in a positive and negative way. In consequence the journal is a very mixed read. You will frequently learn nothing from an entire issue, simply because 'your' chromosome or region or gene is not discussed.

Ultimately, a human or mouse gene map is too complex to exist on anything other than a computer database, and much of the information in *Genomics* could be submitted directly to the database curators. Unfortunately publication in a computer database is not considered legitimate, and convention dictates that publications must follow from grant funding, or precede promotion applications. Eventually this may change and one of the main roles of *Genomics* would disappear.

Until then, the journal remains safe. It is without doubt the flagship of gene mappers. There are competitors: for example, *Nucleic Acids Research* publishes large numbers of one-page RFLP reports, but the exact usefulness of these, which often contain bald statements with no verifiable data, is rather ambiguous and the articles in *Genomics* are clearly of greater weight. Several cytogenetic and genetic journals also publish important papers. But they tend to be embedded in classical studies which, although critical to future development, are at a level less basic than gene mapping.

Probably the journal's only fault, if fault it is, is that it has not performed particularly well as a vehicle for the presentation of new technologies. Given that the whole field is technology driven, this could turn out to be a serious weakness, though recent issues show signs that the balance might be changing.

Anyone interested in gene mapping has to read *Genomics*, which is no mean achievement given that the journal was launched only two years ago. That many of its papers contain very little information, gained at the expense of much labour, is not the point; it is the construction of the whole that is important. One day *Genomics* will stop publishing mapping papers and become a collection agency for a computer database. Until that becomes an acceptable means of communication, the journal will occupy the premier publication slot in a hugely expanding area of molecular genetics. □

On the brain

Guy Goodwin

Journal of Psychopharmacology. Managing editor R. Maggs. *Oxford University Press. 4/yr. UK £50, EEC £54, North America $108, elsewhere £60*
Neuropsychopharmacology. Editor-in-chief J. Christian Gillin. *Elsevier. 6/yr. US$148, elsewhere $172 (institutional); US$96, elsewhere $120 (personal), US $34 elsewhere $58 (student).*

PHARMACOLOGY means far more to psychiatry than just treatment with drugs, in that pharmacological methods provide a way of analysing brain mechanisms and so of identifying abnormalities of transmitter function in psychiatric illness. Other disciplines within the neurosciences, and now also molecular genetics, are

competing to illuminate the nature of mental illness; but pharmacology, by linking therapeutics on the one hand and receptor function on the other, is still the most important of the sciences basic to psychiatry.

It is not surprising to find new journals devoted to a fusion between pharmacology, psychology and psychiatry. Furthermore, there is little doubt that there is good work to publish. The problem, as for all multi-disciplinary journals, is to maintain focus and avoid being a repository for research that is not quite good enough to be accepted by the mainstream journals in pharmacology and psychiatry. *Journal of Psychopharmacology* and *Neuropsychopharmacology* both have the advantage of originating in societies: the British Association for Psychopharmacology for the first and the American College of Neuropsychopharmacology for the second. Both are now in their second volumes, how are they doing?

Journal of Psychopharmacology aims to publish editorials, reviews, original papers, book reviews and abstracts of meetings. Its contents page does not make a clear distinction between reviews and original papers which may be because it has clearly had difficulty in attracting good-quality research reports. Indeed, the appearance of numbers 3 and 4 for 1988 in a single issue containing only two full papers with original material, looks dangerously like bankruptcy. A particular problem for the journal as a British–European publication is that *two* other direct competitors appeared at about the same time (*Human Psychopharmacology*, published by Wiley, and *International Journal of Psychopharmacology*, from Clinical Neuroscience Publishers). Success may ultimately depend upon the vitality of its parent association.

Neuropsychopharmacology is a direct American equivalent to *Journal of Psychopharmacology*, not only in originating in a learned society but in having similar aims and similar composition. It has maintained a higher rate of publication of original papers, although some of these on closer inspection appear to be re-mixes of similar data published elsewhere. Nevertheless, the journal is attracting reasonable basic-science articles and good clinically orientated papers. It clearly benefits from the swing to biologically orientated research in American psychiatry. □

Guy Goodwin is in the MRC Brain Metabolism Unit, Royal Edinburgh Hospital, Edinburgh EH10 5HF, UK

Special needs

C. J. Marshall

Molecular Carcinogenesis. Editors-in-chief Thomas J. Slaga and Stuart H. Yuspa. *Alan R Liss. 6/yr. US $190, elsewhere $241 (institutional); US $90, elsewhere $120 (personal).*

ALTHOUGH the best papers on oncogenes and molecular aspects of carcinogenesis can still be assured of publication in the high-profile general journals, the huge increase in work in this area and the dictates of editorial fashion have created a need for specialist journals. To my knowledge, *Oncogene* and *Oncogene Research* were the first of this new generation, and these journals are now well established.

What then of the relative newcomer *Molecular Carcinogenesis*, which was started in 1988? Its editors-in-chief propose that it should be a forum for papers describing molecularly orientated research which has direct biological implications. Such an aim is highly laudable, and achieving it looks likely given the distinguished editorial board which draws in experts from many different aspects of cancer research.

On the evidence of the material that has been published to date, the journal obviously has some overlap with *Oncogene* and *Oncogene Research*. Topics such as oncogene activation in human tumours and experimental systems, and changes in gene expression in tumours, provide common ground. There are, however, distinct differences in scope. Reflecting the background of many of the editorial board members, there is a strong representation of studies on chemical carcinogenesis. This is very appropriate, given the significance of chemical carcinogenesis in the induction of human malignancy and the importance of chemical carcinogenesis models in animals in providing reproducible systems in which oncogene activation can be studied. In contrast, there is little coverage of topics such as the biochemical functions of oncoproteins.

Molecular Carcinogenesis therefore mainly provides a perspective on how genetic changes may arise in tumour cells rather than on how those changed genes alter all behaviour. Such a perspective is clearly valuable, and the journal should provide an excellent place for the publication of work in this area. □

C. J Marshall is in the Section of Cell and Molecular Biology, Institute of Cancer Research, Chester Beatty Laboratories, Fulham Road, London SW3 6JB, UK

Protein produce

W.R. Arathoon

Cytotechnology: International Journal of Cell Culture and Biotechnology. Managing editors J.B. Griffiths, D W. Barnes and H Murakawi. *Kluwer. 6/yr. Dfl.552, $258 (institutional); Dfl.270, $128 (individual).*

ANIMAL-cell culture and related cell biology technologies are taking an increasingly high profile. There is growing demand for the complex proteins from animal cells, be they antibodies, hormones, growth factors, enzymes or vaccines, which are now often made using recombinant DNA techniques. *Cytotechnology* addresses the needs of this new field, dealing with both

International Journal of Cell Culture and Biotechnology

the pure and the applied aspects. No other journal has been directed specifically to this end.

All aspects of normal and transformed cells and hybridomas are covered. Articles range from descriptions of the use of *in situ* hybridization techniques (of cells and chromosomes) to accounts of new equipment for exploiting cells and characterizing and purifying their products. Probably not to be found in *Cytotechnology* are reports of the most recent advances in molecular cell biology, which vie for space in the fast-moving, prominent journals. Rather, here you can discover new ways of generating or activating cell lines, new growth-factor activities, more efficient culture systems and formulations for better media.

Cytotechnology contains no glossy

advertisements — its contents are strictly down to earth. As well as research articles, it features good, short reviews, technical notes, and reviews of books, meetings and workshops. The format and layout are good. The illustrations are clear and all the print can be read without using a magnifying glass. No issues I've seen contain coloured photographs — perhaps for economy — but surprisingly this does not appear to be an obvious defect.

As might be expected of such a new, international journal, the papers published to date have been of variable quality. Most are of interest, nonetheless, and the short reviews are useful reference works. The speed of publication of papers after receipt averages about five months, which is fairly typical for many journals of this type. There are no sections for correspondence or editorials: because the field is advancing fast, both may become desirable.

This is a practical and valuable publication for those working with animal cells in many areas. As cells are used increasingly to search for and produce useful biologically active molecules, more people will be reading *Cytotechnology*. □

W.R. Arathoon is in the Department of Cell Culture Research and Development, Genentech, Inc., 460 Point San Bruno Boulevard, South San Francisco, California 94080, USA

Light thickens

Bob Ford

Journal of Photochemistry and Photobiology B: Biology. Editor-in-chief G. Jori. *Elsevier Sequoia. 12/yr. SwFr. 900.*

This new journal has been created through the efforts of the European Society of Photobiology after unfruitful negotiations to share the established journal of the American Society for Photobiology (*Photochemistry and Photobiology*). The undaunted Europeans decided to join up with the old *Journal of Photochemistry*, which was renamed (apparently by committee) and split into two sections, *Chemistry (A)* and *Biology (B)*.

The scope extends to any biological phenomenon involving light. Thus in the first few issues one can find several excellent articles which illustrate the journal's wide potential. These include assessment of the use of light to treat neonatal jaundice; new data on the ultra-fast kinetics of photosynthetic energy conversion; studies on the adaptation of microorganisms to changing light regimes; predictions of the effect of the ozone hole on skin cancer; and a delightful description of the restoration of art works in the Brancacci Chapel in Florence using reflectance spectroscopy as a guide. Here is a healthy mix of articles, mostly of a high standard of presentation and of fairly wide importance.

There are, however, troubles ahead if the average handling time of papers is not reduced. Currently the delay seems to be approaching eleven to twelve months from the submission of the article to its publication. Naturally, authors who think their data is of burning importance will be tempted to go elsewhere. The problem is that the journal has been a victim of its own success — the editors have been flooded with manuscripts, leading to a long queue of accepted papers waiting for a space. The editorial board are attempting to improve matters by expanding the current volume and have negotiated a doubling of the number of issues per year to twelve.

Why should there be such a demand for an outlet in this area? One reason is that photobiology has been relatively poorly served by journals, with *Photochemistry and Photobiology* traditionally dominating the field. Also, the expanding interface between photochemistry and medicine has not, as yet, been fully explored by publishers. For instance, the development of phototherapy for the treatment of certain cancers is perhaps the most rapidly growing area of photobiology at the moment.

The new journal does cater for the more rapid dissemination of information in a News and Views section where current results can be discussed informally. This section is novel and interesting, giving the journal a refreshingly open feel in allowing the public exchange of views between contributors. In addition there are the longer invited review articles, the fully refereed research papers, an occasional book review and space for the newsletter of the society.

In general the reproduction quality is good, but the uninteresting cover design, small size and overlong name of the journal may put off the browsing reader. A further drawback is that librarians may be undecided as to its correct location. Should it go next to its sister publication in the chemistry library, or with biology and medicine? I would strongly recommend the latter — in my experience, biologists and medics rarely stray into chemistry libraries.

The journal is certainly not cheap, but with the recent agreement by the publishers to double the number of issues per year, it seems to be in good shape and looks likely to prosper. □

Bob Ford is in the Department of Biophysical Chemistry, Biozentrum, University of Basel, Klingelbergstrasse 70, CH-4056 Basel, Switzerland

Bottom lines

Peter D. Moore

Journal of Paleolimnology. Editor John P. Smol. *Kluwer. 6/yr. Dfl.476, United States $223 (institutional); Dfl.230, US $108 (individual).*

How can one define palaeolimnology (or paleolimnology if you come from the other side of the pond)? The subject is the study of ancient lake sediments, but there are researchers who analyse such sediments without strictly deserving the title palaeolimnologists. There are palynologists, for example, who extract fossil pollen grains preserved in the sediments in order to reconstruct vegetation history within the lake catchment and beyond. They use the fact that sediments are chronologically stratified to provide a time sequence for their work, but they are not usually specifically concerned with the history and development of the lake. The palaeolimnologist is more interested in autochthonous rather than allochthonous fossils, in the story of the lake rather than its catchment.

This new journal therefore does not deal with general environmental history. Rather it contains papers on lake levels, diatoms, chrysophytes, crustacea, caddis flies and chydorids, all of which provide information on the history of a particular lake. Some articles cover research techniques that have implications for catchment history. The inwash of clastics and

journal of paleolimnology

the accumulation of heavy metals, for example, provide a link between aquatic and terrestrial palaeoecology. Biogeographers may also need to turn to palaeolimnology to solve some of their problems, such as questions of endemicity in fish (gobies from Japanese lakes find their way into the journal). Papers on techniques for the recovery of sediment cores from lakes and for the preparation of fossils from the sediments are also evidently acceptable.

Paleolimnology thus has a specialist niche to itself and has avoided an excessive intake of palaeoenvironmental papers for which there are many alternative publication media. Such specialization has advantages in terms of reduced competition from other journals, but it also has the disadvantage of a restricted market. One can only guess about the long-term success of this strategy, but I feel that the distinctive flavour of *Paleolimnology* should appeal to enough researchers to ensure its continued viability. □

Peter D Moore is in the Division of Biosphere Sciences, King's College London, Campden Hill Road, London W8 7AH, UK.

THE NATURAL SELECTION

Trends in Ecology and Evolution (TREE) captures the essence of current research in all areas of ecology and evolutionary biology. These two fields have witnessed revolutionary advances in the 1980s, and both have ever-increasing importance in the face of the gathering momentum of global environmental change and destruction. The modern ecologist and evolutionary biologist, more than ever before, needs to be aware of new developments across a wide range of disciplines. More than any other journal, TREE fulfils that need.

"Trends in Ecology and Evolution is uniformly excellent, having established itself in only two years as a 'must read' journal. The quality of the articles is very high, and the review articles not only summarize the literature but evaluate it critically." - Nature

TREE is just one of the eight TRENDS review journals from Elsevier. The others cover biochemistry and molecular biology, biotechnology, genetics and development, immunology, neuroscience, parasitology and pharmacology.

Oncogene RESEARCH

Editors In Chief

Claudio Basilico, *New York University School of Medicine, USA*
Hidesaburo Hanafusa, *The Rockefeller University, USA*

Editors

Lionel Crawford, *Imperial Cancer Research Fund, UK*
François Cuzin, *Universitē de Nice, France*
Thomas Graf, *European Molecular Biology Laboratory, FRG*
Charles D. Stiles, *Dana-Farber Cancer Institute, USA*
Inder M. Verma, *The Salk Institute, USA*
Michael H. Wigler, *Cold Spring Harbor Laboratory, USA*

Oncogene Research is a monthly journal dedicated to reports of significant research in the genetics, molecular and cellular biology of oncogenes, their products and the factors involved in the regulation of growth of normal and cancer cells.

Recent and Forthcoming Papers

Removal of an mRNA Destabilizing Element Correlates with the Increased Oncogenicity of Proto-Oncogene *fos* • **V. Raymond, J. Atwater and I. Verma.**

Alterations in the Expression of $pp60^{c\text{-}src}$ and $p56^{lck}$ Associated with Butyrate-Induced Differation of Human Colon Carcinoma Cells • **F. Foss, A. Veillette, O. Sartor, N. Rosen and J. Bolen.**

Transfection of Normal and Transformed Hamster Cerebral Cortex Glial Cells with Activated c-H-*ras*-1 Results in the Acquisition of a Diffusely Invasive Phenotype • **J. Fetherston, J. Cotton, J. Walsh and S. Zimmer.**

Expression of the *K-fgf* Protooncogene is Repressed During Differentiation of F9 Cells • **A. Velcich, P. Delli-Bovi, A. Mansukhani, E. Ziff and C. Basilico.**

Localization of Cellular *src* mRNA During Development and in the Differentiated Bipolar Neurons of the Adult Neural Retina in *Xiphophorus* • **F. Raulf, W. Mäueler, S. Robertson and M. Schartl.**

In vivo Phosphorylation States and Kinase Activities of Transforming $p60^{c\text{-}src}$ Mutants • **R. Jove, T. Hanafusa, M. Hamaguchi and H. Hanafusa.**

Expression of Human and Viral *ets* Genes in *E. Coli* Production of Human *ets*-2-Specific Monoclonal Antibodies • **A. Seth, D. Watson, S. Fujiwara, S. Showalter and T. Papas.**

Mode of *c-myc* Gene Regulation in Folic Acid Induced Kidney Regeneration • **C. Asselin and K. Marcu.**

The Chromosome 11 Region Flanking the t(11;14) Breakpoint in Human T-ALL is deleted in Wilms' Tumor Hybrids • **S.N. Finver, C. Martiniere, J. Kagan, W. Cavanee and C.M. Croce.**

Regulation of *C-myc* m-RNA Levels by Insulin or Platelet Poor Plasma • **X. Gai, M-G Rizzo, S. Valpreda and R. Baserga.**

Characterization of the *ros*1-Gene Products Expressed in Human Glioblastoma Cell Lines • **S. Sharma, C. Birchmeier, J. Nikawa, K. O'Neill, L. Rodgers, M. Wigler.**

A Single Amino-Acid Substitution in the DNA-Binding Domain of the myb Oncogene Confers a Thermolabile Phenotype to E26-Transformed Myeloid Cells • **R. Li, M. Duterque-Coquillaud, C. Lagrou, B. Debuire, T. Graf, D. Stehelin, D. Leprince.**

Identification of a Small Region of the v-fos Gene Product that is Sufficient for Transforming Potential and Growth-Stimulating Activity • **T. Yoshida, Y. Shindo, K. Ohta, H. Iba.**

Transformation by Basic Fibroblast Growth Factor Requires High Levels of Expression: Comparison with Transformation by hst/K-fgf • **N. Quarto, D. Talarico, A. Sommer, R. Florkiewicz, C. Basilico, D.B. Rifkin.**

JOURNALS FROM WORLD SCIENTIFIC PUBLISHING

International Journal of Neural Systems *(IJNS)*

NEW

Covering information processing in natural and artificial neural systems, this journal will present a fresh, undogmatic attitude towards this multi-disciplinary field with the aim to be a forum for novel ideas and improved understanding of collective and cooperative phenomena in systems with computational capabilities.
Editor-in-Charge: B Lautrup (Niels Bohr Inst., Denmark).
Assistant Editor-In-Charge: S Brunak (Tech. Univ. of Denmark)
Published quarterly, ISSN: 0129-0657. Subscription rates for 1990, Institutions/Libraries US$88. Individuals US$42. Institutions/Libraries from developing countries US$38. (add US$9 for surface mail, US$17 for airmail).

International Journal of High Speed Computing *(IJHSC)*

NEW

Directed at researchers, educators and engineers in the field of parallel computations and aims to foster the advance of the state-of-the-art in the field. The journal will cover Parallel algorithms, software environments for parallel computing and architecture for vector and parallel computers.
Managing Editors: D Gannon (Indiana Univ., USA), A Lichnewsky (INRIA, France), Y Muraoka (Waseda Univ., Japan) and A Sameh (Univ. of Illinois, Urbana-Champaign, USA).
Published quarterly, ISSN: 0129-0533. Subscription rates for 1990, Institutions/Libraries US$165. Individuals, Institutions/Libraries from developing countries US$72. (add US$25 for airmail).

Reviews in Mathematical Physics *(RMP)*

NEW

A review journal consisting of introductory and survey papers of interest to Mathematical physicists, mathematicians and theoretical physicists interested in interdisciplinary topics covering areas among others, gauge fields, quantum field theory, statistical mechanics, dynamical systems, functional analysis and interactions between theoretical physics and pure mathematics.
Chief Editor: H Araki (RIMS, Kyoto).
Published quarterly, ISSN: 0129-055X. Institutions/Libraries US$185. Individuals, Institutions/libraries from developing countries US$75. (add US$25 for airmail).

International Journal of Modern Physics A *(IJMPA)*

24 issues including 2 supplements, ISSN: 0217-751X. Subscription rates for 1990, Institutions/Libraries US$545, (add US$68 for airmail, US$20 for surface mail). Individuals, Institutions/libraries from developing countries US$240 (add US$80 for airmail)

International Journal of Modern Physics B *(IJMPB)*

16 issues including 4 supplements, ISSN: 0217-9792. Subscription rates for 1990, Institutions/Libraries (airmail inclusive) US$485. Individuals, Institutions/libraries from developing countries US$192 (add US$45 for airmail).

Concepts in Neuroscience *(CINS)*

NEW

A theoretically oriented journal presenting opportunities for researchers specializing in areas including anatomy, physiology, biochemistry, psychophysics, mathematical modelling to exchange ideas and express in a coherent simplified manner new concepts concerning the working of the brain. It encourages researchers to write articles going beyond technicalities, mathematical proofs or experimental data.
Editors-In Chief: G Palm (F R Germany) and G L Shaw (USA).
Published bi-yearly, ISSN: 0129-0568. Subscription rates for 1990, Institutions/Libraries US$85. Individuals, Institutions/Libraries from developing countries US$42. (add US$25 for airmail).

International Journal of Foundations of Computer Science *(IJFCS)*

NEW

Carries critical reviews, research papers and correspondences on new theoretical results in all areas of foundations of computer science. Its wide coverage includes topics like algebraic theory of computing, combinatorics, complexity theory, logic and semantics of programs. Features also proposals for deepening understanding of computation.
Managing Editors: E Engeler (ETH-Zurich), T Ito (Tohoku Univ.), R Parikh (CUNY) and A Rosenberg (Univ. of Massachusetts).
Published quarterly, ISSN: 0129-0541. Subscription rates for 1990, Institutions/libraries US$160, Individuals, Institutions/Libraries from developing coutries US$70. (add US$25 for airmail).

International Journal of PIXE *(PIXE)*

NEW

IJPIXE seeks to enhance communication among basic and applied scientists by publishing perspective articles in rapidly developing fields of particle-induced X-ray emission and its related phenomena.
Published quarterly, ISSN: 0129-0835. Subscription rates for 1990, Individuals/Institutions/libraries US$240 (add US$25 for airmail).

International Journal of High Speed Electronics *(IJHSE)*

NEW

Published quarterly, ISSN: 0129-1564. Subscription rates for 1990, Institutions/Libraries US$150. Individuals US$75 Individuals, Institutions/Libraries from developing countries US$68 (add US$30 for airmail).

International Journal of Pattern Recognition and Artificial Intelligence *(IJPRAI)*

Published quarterly, ISSN: 0218-0014. Subscription rates for 1990, Institutions/libraries (airmail inclusive) US$260. Individuals, Institutions/Libraries from developing countries US$108 (add US$30 for airmail).

NEW SCIENCE AND TECHNOLOGY JOURNALS FROM BUTTERWORTHS

Food Control

Announcing the launch of a new, highly topical journal dealing with all aspects of food control. At a time when the food industry throughout the world has to keep pace with changes in food production and consumption, particularly in relation to safety, Food Control will be an essential information tool for all those involved in this field.

First quarterly issue due: January 1990 *ISSN 0956-7135*

Human Antibodies and Hybridomas

This new journal will bring together all aspects of human hybridomas and antibody technology under a single, cohesive theme This includes fundamental research, applied science and clinical applications.

First quarterly issue due: April 1990 *ISSN 0956 960X*

The Journal of Nutritional Biochemistry

The primary focus of this new journal will be on investigations about nutrients that overlap with areas claimed by biochemistry, molecular biology, neurochemistry, toxicology or pharmacology.

First monthly issue due January 1990 *ISSN 0955 2863*

Interacting with Computers

This major new journal acts as an international forum for the discussion of human-computer interaction issues It makes information accessible not only to those engaged in research but to all HCI practitioners

Published in April, August and December *ISSN 0953 5438*

Flow Measurement and Instrumentation

Scheduled for publication in October 1989 this specialist journal is concerned with the measurement and instrumentation of single phase liquid and gas flows; multiphase flows having solid, liquid and gas phases; and the measurement of slurries and pastes

First quarterly issue due: October 1989 *ISSN 0955 5986*

Composites Manufacturing

This new quarterly journal, sister title to the leading journal Composites will contain refereed papers on the latest advances in design, processing, fabrication and production of resin matrix/metal matrix/ceramic matrix and concrete composites.

First quarterly issue due. Spring 1990 *ISSN 0956 7143*

If you would like a free sample copy of any of the above journals complete and return the coupon to Philip Shaw, Butterworth Scientific Ltd, PO Box 63, Westbury House, Bury Street, Guildford, Surrey GU2 5BH, UK Reader Service No.9

PART OF REED INTERNATIONAL P.L.C.

NEW from Elsevier:

Journal of Dermatological Science

The Official Journal of the Japanese Society for Investigative Dermatology.

Editor-in-Chief:
Hideoki Ogawa, Department of Dermatology, *Juntendo University, School of Medicine, 2-1-1, Hongo, Bunkyo-Ku, Tokyo 113, Japan.*

Associate Editors:
Masamitsu Ichihashi *(Kobe)* , **Tamotsu Kanzaki** *(Nagoya)*
Itsuro Matsuo *(Isehara)*, **Kenji Takamori** *(Tokyo)*

The *Journal of Dermatological Science* will publish high quality peer-reviewed manuscripts covering the entire scope of dermatology, from molecular studies to clinical investigations. Laboratory and clinical studies which provide new information will be reviewed expeditiously and published in a timely manner.

The Editor and his Editorial Board especially encourage the publication of research based on a process of bilateral feedback between the clinic and the laboratory, in which incompletely understood clinical phenomena are examined in the laboratory and the knowledge thus acquired is directly reapplied in the clinic. This continuous feedback will refine and expand our understanding of both clinical and scientific domeins.

Although the Journal is the official journal of the Japanese Society for Investigative Dermatology, it will serve as an international forum for the work of all dermatological scientists. With an internationally renowned Editorial Board, the Journal will maintain high scientific standards in the evaluation and publication of manuscripts. The Journal will also publish invited reviews, commentaries, meeting announcements and book reviews. Short communications reporting new results will also be encouraged.

Subscription Information: 1990: Volume 1 (1 volume in 6 issues)
Price: Dfl. 385.00/US$ 176 50 including postage and handling costs
ISSN 0923-1811

NOW PUBLISHED BY ELSEVIER -

The EUROPEAN JOURNAL OF RADIOLOGY including Journal of Medical Imaging

Editors-in-Chief:
J.H. Göthlin, *Central Department of Diagnostic Radiology, Sahlgrenska University Hospital, S 41345 Göteborg, Sweden*

H.E. Schutte, *Department of Radiology, University Hospital Dijkzigt, Dr. Molewaterplein 40, 3015 GD Rotterdam, The Netherlands*

Assistant Editor: J.A.M. Lemmens, *Nijmegen, The Netherlands*

The *European Journal of Radiology* (EJR) is an international journal which acts as a medium for the exchange of information on the use of radiological and allied medical imaging techniques in clinical diagnosis and practice and of interventional techniques.
Original articles on roentgenology (including digital radiology), computer tomography, magnetic resonance, ultrasound and nuclear medicine will be considered. Review articles on novel imaging techniques, updates of existing clinical practice and evaluations of technical equipment will also be published.
Technical notes and letters to the editor are encouraged.
Case reports will be published, but emphasis will be laid on brevity (3 pages) and high scientific or educative content.

Subscription Information: 1990: Vols. 10-11 (2 volumes in 6 issues)
Institutional rate: Dfl. 656.00/US$ 301.00 ISSN 0720-048X

Introducing

SAUNDERS SCIENTIFIC PUBLICATIONS

W.B. SAUNDERS

Original research at the frontiers of cell and molecular biology

The New Biologist

Editor-in-Chief: Arthur S. Levine, National Institutes of Health; *European Editor:* David P. Lane, Imperial Cancer Research Fund

To encourage the development of unifying theories in cell and molecular biology, *The New Biologist* is dedicated to the rapid publication of insightful reports on a diversity of biological systems and models.

Inaugural Issue: October 1989
Published monthly. 1-year subscription rates:
US: $125 individuals; $225 institutions
Rest of world: $160 individuals; $260 institutions

Dynamic, international forum for the dissemination of information on cytokines

Cytokine

Editors: Gordon W. Duff, University of Edinburgh and Scott K. Durum, National Cancer Institute

Original, high-quality work on all cytokines, including interleukins, cytotoxins, hematopoietic factors, transforming growth factors, interferons and other known or new cytokines.

Inaugural Issue: November 1989
Published bimonthly. 1-year subscription rates:
US: $125 individuals; $250 institutions
Rest of world: $150 individuals; $275 institutions

Rapid publication of the latest methodological advances

Technique

A Journal of Methods in Cell and Molecular Biology

Editor: Peter Little, Imperial College of Science and Technology; *US Editor:* Stephen Hughes, National Cancer Institute

Exceptionally detailed, step-by-step protocols provided for each article are highlighted for easy identification and utility at the lab bench.

Inaugural Issue: August 1989
Published bimonthly. 1-year subscription rates:
US: $125 individuals; $210 institutions
Rest of world: $150 individuals; $235 institutions

Saunders Scientific Publications

Seminars in the Life Sciences

Each issue of the *Seminars* series, edited by a specially selected guest editor, features in-depth reviews of a single topic that are lively, readable and most importantly, substantive enough to cite in your own work. Rigorous editorial direction and a rapid publication process ensure currency of information.

- *Seminars in Cancer Biology*
- *Seminars in Cell Biology*
- *Seminars in Developmental Biology*

New Journals from

Comments on Theoretical Biology

Chief Editor: J. Joseph Blum, Department of Physiology, Duke University Medical Center, Durham, NC, USA

A focus for comment and discussion on developments in all facets of biological research. **Comments on Theoretical Biology** evaluates recent theoretical analyses of biological systems from the sub-cellular to the population level.

Volume 1 (6 issues)
Subscription rates per volume:
Corporate $240.00
University library $162.00
*Individual $90.00**

A Gordon and Breach journal

Comments on Developmental Neurobiology

Editor in Chief: A. Prochiantz, Groupe NB, Collège de France, Paris, France

Comments on Developmental Neurobiology publishes critical reviews of recent progress in the field. An article may cover any stage of development from the embryo to the ageing organism.

Volume 1 (6 issues)
Subscription rates per volume:
Corporate $260.00
University library $174.00
*Individual $98.00**

A Gordon and Breach journal

Historical Biology

An International Journal Of Paleobiology

Editor: E. Buffetaut, Laboratoire de Paleontologie des Vertebres, Université Paris VI, 4 Place Jussieu, Paris, France

Historical Biology will emphasize modern developments and controversial topics, and will cross the boundaries of biology, molecular biology/biochemistry, and the earth sciences. It covers paleobiology, paleoecology, evolution and functional morphology, phylogeny, historical biogeography, evolutionary processes and patterns, extinction phenomena, and molecular paleontology.

Volume 3 (4 issues)
Subscription rates per volume:
Corporate $186.00
University library $122.00
*Individual $48.00**

A Harwood journal

Growth Factors

Editor in Chief: A. Burgess, Ludwig Institute for Cancer Research, Melbourne, Australia

This international journal aims to keep researchers and clinicians up-to-date with the latest findings in growth factors research. It is dedicated to the communication of significant research, both basic and clinical, on the expression, structure and use of growth factors on cells and animals.

Volume 1 (4 issues)
Subscription rates per volume:
Corporate $190.00
University library $130.00
*Individual $76.00**

A Harwood journal

First issue November 1989

Leukemia and Lymphoma

Editor: A. Polliack, Royal Marsden Hospital, London, UK

Aiming at a strong clinical-pathologic correlation, this journal brings together clinical and laboratory data on lymphomas, leukemias and allied disorders including myeloma and myelodosplastic syndromes.

Volume 1 (6 issues)
Subscription rates per volume:
Corporate $200.00
University library $150.00
*Individual $86.00**

A Harwood journal

Forthcoming . . .

Sequence
The Journal of DNA Mapping and Sequencing

Editor in Chief: B. G. Barrell, MRC Laboratory of Molecular Biology, Hills Road, Cambridge, UK

The journal will publish mapping data (that would be useful to future DNA sequencing), DNA sequence data in full, new sequencing procedures, analyses of DNA sequences, computer methods, compilations of sequence motifs, regular reviews, and provide a forum for the exchange of research and experience and advice, through a Letters to the Editor section.

Volume 1 (6 issues)
Subscription rates per volume:
Corporate $200.00
University library $130.00
*Individual $76.00**

A Harwood journal

Accountability In Research
Policies and Quality Assurance

Editor in Chief: A. E. Shamoo, University of Maryland School of Medicine, Baltimore, MD, USA

Accountability In Research is a timely new publication, providing a medium for the critical examination of issues involving the integrity of scientific data.

Volume 1 (4 issues)
Subscription rates per volume:
Corporate $180.00
University library $120.00
*Individual $60.00**

A Gordon and Breach journal

ANNOUNCING FOR 1990

TETRAHEDRON: ASYMMETRY

The International Journal for Rapid Publication on all Aspects of Asymmetry in Organic, Inorganic, Organometallic, Physical Chemistry and Bio-Organic Chemistry

Editor-in-Chief: **S G DAVIES**, *The Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY, UK, (Fax 0865-275633)*

Assisted by a Consulting Board of Editors

Tetrahedron: Asymmetry presents experimental or theoretical research results of outstanding significance and timeliness on asymmetry in organic, inorganic, organometallic and physical chemistry, as well as its application to related disciplines, especially bio-organic chemistry. The journal will publish critical reviews, original research articles and preliminary communications dealing with all aspects of the chemical, physical and theoretical properties of non-racemic organic and inorganic materials and processes.

CALL FOR PAPERS

SEND FOR A FREE SAMPLE COPY WHEN AVAILABLE

Topics relevant to the journal include: the physico-chemical and biological properties of enantiomers; strategies and methodologies of asymmetric synthesis; resolution; chirality recognition and enhancement; analytical techniques for assessing enantiomeric purity and the unambiguous determination of absolute configuration; and molecular graphics and modelling methods for interpreting and predicting asymmetric phenomena.

Papers describing the synthesis or properties of non-racemic molecules will be required to include a separate statement, for publication in the same issue, of the criteria used for the assignment of configuration and enantiomeric purity.

Subscription Information
1990: Volume 1 (12 issues)
Annual subscription (1990) DM 550.00
Two-year rate (1990/91) DM 1045.00
ISSN: 0957-4166

Subscribers to Tetrahedron will receive Tetrahedron: Asymmetry as part of their subscription.

German Mark (DM) prices quoted apply in Europe, Africa, Asia/Australasia (with the exception of Japan) For the rest of the world including Japan apply to the nearest Pergamon Office Prices and proposed publication dates are subject to change without prior notice Prices include postage and insurance Advertising rate card available on request

Past futures

Andrew H. Knoll

Historical Biology: An International Journal of Paleobiology. Editor E. Buffetaut. *Harwood. $186 (institutional); $122 (university library); $48 (personal) per volume.*

PALAEONTOLOGISTS seem to enjoy two sports — predicting the imminent demise of their discipline and starting new journals Despite numerous Cassandras, it is the second pursuit that better indicates the field's state of health. In science's modified oral tradition, palaeontologists are increasingly the keepers of systematic and morphological knowledge; the fossil record continues to provide new insights into and challenges for evolutionary biology; and as concern over global change grows, the sensitive responses of organisms to past environmental changes provide the basis for a vigorous new partnership between palaeontology and geology. To accommodate expanding research, new journals have arisen regularly over the past dozen years. The latest is *Historical Biology*.

In his prefatory remarks to the first issue, Eric Buffetaut states that *Historical Biology* will publish papers on "paleobiology, paleoecology, evolution and functional morphology, phylogeny, historical biogeography, evolutionary processes and patterns, and extinction phenomena, as well as molecular paleontology". Given that aim, one might well wonder whether the journal is to be all things to all palaeontologists (with consequently limited chances of success), or whether it will settle into a niche that differentiates it from existing outlets.

Initial results are unclear. *Historical Biology* shares several features with established English-language journals: its contents are generally if not invariably of a good standard; authors are drawn principally but not exclusively from North America and Western Europe; and its subject organisms are predominantly marine invertebrates, with a healthy admixture of vertebrate palaeontology, a few papers on skeletonized protists and plants, and virtually nothing on organic-walled microfossils. Among established journals, character displacement occurs mainly in disciplinary approach. The *Journal of Paleontology* and *Palaeontology* concentrate principally on systematics and morphology. *Paleobiology* features quantitative analyses informed by evolutionary theory. *Lethaia* also looks to biology, but in this case it is functional biology and ecology. *Palaios*, in contrast, draws its inspiration from sedimentary geology, publishing mainly on palaeoecology, taphonomy and stratigraphy.

One might well argue that palaeontological studies of evolution should embrace all these methodologies, and true to its editorial claim, *Historical Biology* has taken a catholic approach. Its first issues contain such (now) standard fare as a functional analysis of pterosaur locomotion, conodont biogeography, and an essay on trilobite monophyly, as well as more unusual offerings such as a curious but interesting account of the Great Auk, an eclectic essay on plant evolution, and data on the metabolic flexibility and ecological tolerance of brachiopods. A special issue has also been devoted to mass extinctions. Although the journal as a whole includes diverse perspectives, most individual papers still follow a single approach, much as in established journals.

It will be interesting to watch the evolution of this journal. If *Historical Biology* can encourage rigorous, multidimensional analyses of palaeontological pattern interpreted in the context of continuing changes in both the physical and biological environment, it will become a significant voice in palaeontology. As an old but newly revitalized discipline looks to the future, this, as much as anywhere, is where palaeontology's unique contributions to geology and biology will be made.

Andrew H. Knoll is in the Botanical Museum, Harvard University, 26 Oxford Street, Cambridge, Massachusetts 02138, USA.

Not so shaky

Peter D. Marshall

Earthquake Research In China. Editor-in-chief Chen Yong. *Allerton, New York. 4/yr. North America $280; elsewhere $295.*
Acta Seismologica Sinica. Editor-in-chief Chen Yuntai. *Pergamon 4/yr. DM550.*

CHINA has a remarkable record on earthquake prediction, so the appearance of two new journals consisting entirely of papers in English on the nation's earthquake phenomenology and seismological research should be of interest to seismologists throughout the world. Both *Earthquake Research in China* and *Acta Seismologica Sinica* consist of papers which have been translated by their authors from Chinese into English and made widely available by the distribution resources of Western publishing houses. From the look of the journals, it appears that they are printed and bound in China.

Earthquake Research in China is a totally new publication, the first volume of which appeared in 1987. Like *Acta Seismologica Sinica* it is run by a large editorial board, most of whom are employed by the State Seismological Bureau and are

probably responsible for peer review of the contributions. In a statement on publishing policy, Chen Yong, the editor-in-chief, says that although Chinese scientists have kept abreast of research elsewhere, the observational data and research results of Chinese scientists are rarely seen by their foreign counterparts simply because of the language problem. By selecting and publishing translations of papers from almost 30 Chinese-language journals, the editors hope to go at least some way towards rectifying this situation. The journal plans to take contributions on long- and short-term earthquake prediction, risk and hazard estimation and earthquake sociology (a subject which the Chinese naturally regard as very important).

Acta Seismologica Sinica is the journal of the Seismological Society of China and is in many ways similar in publishing policy to the *Bulletin of the Seismological Society of America*. It tends to contain more papers than *Earthquake Research in China* and also includes research notes. In both journals the emphasis is on seismology (though reports on other geophysical aspects of earthquake phenomenology are accepted), and both contain a mixture of theoretical and observational papers, some of which are co-authored by eminent Western seismologists. Westerners should probably not submit papers, however, because this would defeat the objectives of the publishers.

As far as I can make out it can take up to three years from acceptance for a paper to appear in *Acta Seismologica Sinica* and probably a similar time for papers in *Earthquake Research in China*, given the publishing policy. But this time lag doesn't matter too much, because the research results would probably otherwise remain unseen by non-Chinese investigators. The time taken to publish may explain why there is little evidence of use being made of the high-quality digital data from the nine seismograph stations operated as part of a vigorous co-operative programme with the US Geological Survey — it will be interesting to see how long it is before results from these stations percolate through to the journals. China operates over 400 seismograph stations and has over 15,000 technical staff employed on earthquake research, so it is not surprising that the country supports so many seismological journals. ▶

The enthusiasm of the Chinese for making results available to foreign scientists is only to be expected—after all, they have had some spectacular successes in earthquake prediction (as well as a notable failure) and have every right to be proud of their achievements. With regard to seismological data, the Chinese have followed an open policy; they report the data from their nuclear tests to the International Seismological Centre (the Soviet Union has only recently started this practice) and participate actively in the meetings of the UN Group of Scientific Experts where seismological methods of monitoring test-ban treaties are discussed.

The unique work on earthquake prediction, regional seismicity, deep seismic sounding and crustal structure in China is worthy of wide distribution. The two journals reviewed here are of a high standard and certainly help towards filling a gap in the Earth science literature. They should be welcomed — after all seismology is a global science, with researchers world-wide depending on the free exchange of data and ideas to tackle such outstanding problems as earthquake prediction It remains to be seen whether recent events in China perturb the previously open approach to the exchange of scientific information; it would be most unfortunate if they did. □

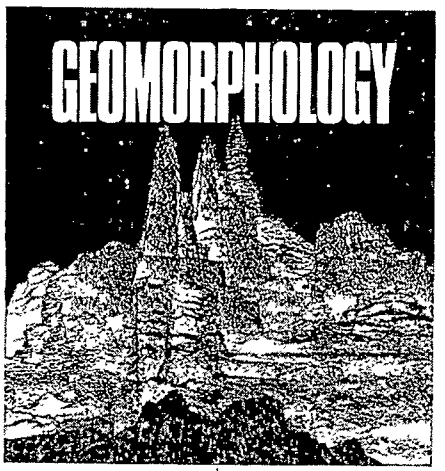
Sixties style

John B. Thornes

Geomorphology. Editor-in-chief M. Morisawa. *Elsevier 8/yr. Dfl. 2928.*



In its early days, at the latter part of the last century, geomorphology was rooted in both geology (in North America) and geography (in Europe). The geologists were mainly interested in what the subject could contribute to Earth's history at a time when they were less preoccupied with geochemistry and geophysics The geographers saw it as the key element in understanding the contemporary landscape, and sought to find out how processes such as weathering, erosion and tectonic activity interacted with rocks to produce the landforms we now see.

Since the late 1950s the historical and mainly descriptive element and the process element have gradually moved further and further apart, each spawning its own specialist journals for historical (mainly Quaternary) studies and for investigations of Earth surface processes and landforms The former has allied with sedimentary geochemistry and palaeobotany, the latter with hydrology, soil physics and chemistry, and hydraulics.

Geomorphologists therefore have a large number of publication outlets; not only are there the three main journals covering the field, but plenty of others dealing with geology, hydrology, geography, soil science and (more recently) environmental issues. So this newcomer has to find a place within a highly competitive environment.

The route the editor has taken is to reoccupy the ground lost in the 1960s by concentrating on the application of contemporary processes to solving problems with a historical dimension. There is also a reassertion of the importance of geology as an underpinning of most if not all geomorphological problems. The methodology has so far emphasized the empirical and descriptive rather than the analytical, and the bridge with Quaternary research has been quickly and effectively reestablished. The journal has a North American provenance and market at a time when the main research and publication thrust had shifted to Europe and European journals

For all these reasons *Geomorphology* has a good chance of success. Too much of intellectual value has been discarded in the past two decades, leaving a disaffected group without a focus of publication. The other main journals, *Catena, Earth*

Surface Processes and Landforms and *Zeitschrift fur Geomorphologie*, each excellent in its own area, failed to attract this wider spectrum of interest.

The main danger, already evident in some of the papers, is that in addition to picking up the abandoned intellectual issues of the 1960s, *Geomorphology* may pick up the abandoned methodologies of the same period. If Morisawa can avoid this pitfall, the journal seems likely to attract a wide readership. □

Entomological action

John Brady

Journal of Insect Behavior. Co-editor William J. Bell and Thomas L. Payne *Plenum 6/yr. United States $135, elsewhere $160 (institutional), US $42.50 elsewhere $50 (personal)*

Hitherto there has not been a journal devoted to insect behaviour On the other hand, there have been others that for years have contained the bulk of the literature on the subject: notably the *Journal of Insect Physiology, Physiological Entomology* and *Comparative Physiology*. These are all of European provenance, however and are concerned more with the mechanisms of behaviour — what the Germans significantly call *Verhaltensphysiologie* – than with its description.

The *Journal of Insect Behavior*, by contrast, is intended to cover almost everything behavioural that can be examined in terrestrial arthropods, including descriptive studies, social behaviour orientation, learning, behavioural modelling and all that which is nowadays called 'behavioural ecology'. It is also an American publication, with half of its editorial board from US institutes and most of its papers from there, too. So, if its expansion from four to six issues a year from its second volume is any indicator, it is evidently fulfilling a need.

Thus far, the quality of its contents have been generally good, although the occasional "Short Communication" (always a doubtful scientific bet) has been distinctly weak Happily, the bulk of its coverage has not yet seriously duplicated its older rivals' interests in behavioural physiology. For those mainly concerned with that area, it is to be hoped that this lack of overlap will continue

At the end of the day, however, it is an editor's job to do more than just publish good science: he also has a duty to maintain the communication of science at a reasonable level of literacy. Without this check and control, scientific communication can degrade into the unreadable, telegraphic and ambiguous. Sadly, this task seems to be taking an increasingly secondary role in scientific editing. Perhaps that is because of the pressure to get out more and more papers faster and faster; or is it just that no one cares any more? In this respect, the literacy of the editors' introductory statement to Vol 1 of the *Journal of Insect Behavior* is not particularly encouraging □

The European identity

Jerry A. Coyne

Journal of Evolutionary Biology. Managing editor S. C. Stearns. *Birkhauser. 6/yr. Swiss franc 288, elsewhere $192; Society members SwFr. 70.*

One of the striking aspects of evolutionary biology is its dominance by anglophones. Although the Society for the Study of Evolution is supposed to be an international organization, 92 per cent of its members are from English-speaking countries and its annual meetings are always held in North America. This has led some evolutionists, particularly in continental Europe, to feel that their contributions are discounted for linguistic reasons.

To provide a more international forum, the European Society of Evolutionary Biology and its official organ, *Journal of Evolutionary Biology*, were created in 1987. According to Stephen Stearns, its

energetic editor, the journal also seeks to fill a void by "bringing together a set of specialities that have not previously shared a common arena for discussion" (Vol. 1, page 2), including systematics, molecular evolution, development, palaeontology, genetics and ecology. Each issue contains about five papers or notes, a few short book reviews and an occasional transcript of a talk from the annual meeting.

After two years, the journal has reached its first goal, but not its second. Thanks to a board of young editors from 13 countries, the quality of the papers is high, nearly equal to that of *Evolution*, by far the best journal in the field. There is also a good geographical mix of authors, more than 40 per cent of them from non-English-speaking countries (*Evolution* has only a third as many). Although rapid publication is not terribly important in this field, the journal is faster than most, with nine to twelve months from submission to print. The illustrations are excellent, and the format (except for the garish red-and-green cover) attractive.

But the gap that *Journal of Evolutionary Biology* seeks to occupy does not exist. For many years it has been comfortably filled — indeed, choked — by journals such as *Evolution*, *The American Naturalist* and *The Biological Journal of the Linnean Society*, all of which cover a variety of evolutionary topics. In addition, the excellent *Trends in Ecology and Evolution* reviews developments in every area of population biology. Except for its high proportion of European authors, *Journal of Evolutionary Biology* is indistinguishable in content from *Evolution*, both of them having many papers on evolutionary quantitative genetics, sex and mating systems, the evolution of development, and life-history optimization. It is hard to see how, short of commissioning interdisciplinary review papers, the editors could create a new and broader perspective.

Unlike species, journals inhabiting the same niche may coexist indefinitely. It is possible that the increasing number of papers in the field or the more European character of the journal will keep it alive. It is also possible that the encouragement of contributors from more countries will elicit novel points of view (this has not happened yet) The editors should, however, fatten up the journal if it can be done without sacrificing quality. Members now pay the equivalent of $2.25 per paper ($4.75 for libraries), nearly seven times the cost of each paper in *Evolution*. This disparity may decrease when more evolutionists realize that *Journal of Evolutionary Biology* is an attractive alternative to older publications. □

Jerry A. Coyne is in the Department of Ecology and Evolution, University of Chicago, 1103 East 57th Street, Chicago, Illinois 60637, USA.

Catastrophism

John Whittow

Natural Hazards: An International Journal of Hazards Research and Prevention. Editors M. I. El-Sabh, G. Schneider and Y. Tsuchiya. *Kluwer. 4/yr. Dfl. 272, North America $127.50 (institutional); Dfl. 125, North America $59 (personal).*

It is hardly surprising that the beginning of the International Decade for Natural Disaster Reduction should be accompanied by the appearance of new journals. Although the topic has been extensively covered by books, both popular and academic, it has hitherto been poorly served by faster-moving specialist media.

The exception has been *Disasters The Journal of Disaster Studies and Management*, which has run for more than a decade As its name suggests, however, this publication is geared primarily to disaster relief and management research rather than to analysis of the physical processes involved (though such studies are by no means excluded). So one has been forced to search through a huge variety of engineering, atmospheric science, Earth science and occasionally social science journals to discover detailed information on natural hazards and their effects.

One should welcome, therefore, the appearance of two new journals in 1988 — *Disaster Management: An International Journal of Contingency Planning for Large Scale Emergencies*, which is published by Argus Press, Redhill, UK, and *Natural Hazards*, the subject of this review. The two differ somewhat, in that the first deals largely with human-induced incidents, while the second is mainly (but not exclusively) concerned with natural events.

Natural Hazards is the journal of the International Society for the Prevention and Mitigation of Hazards, a society spawned from the Rimouski International Symposium on Natural and Man-made Hazards, held in August 1986. The impressive list of 29 members on its editorial board is drawn from a variety of disciplines in no less than 17 countries. The journal has already been recognized as a forum for discussion and as having fostered a beneficial exchange of information between Earth scientists, engineers, planners and other policy makers. The editorial policy is to carry research articles on the physical processes, on the nature of their impact and on how such impacts may be ameliorated both by structural and non-structural means. Moreover, contributions on man-made and technological hazards are invited; it will be interesting to see the results, for there has been a noticeable increase in industrial hazard research during the past decade.

If the four issues of Vol. 1 are anything to go by, the response to the catholicity of the editorial approach has been reasonably successful. A wide selection of articles has been published, ranging in subject matter from earthquakes, volcanoes and debris flows to tsunamis, storm surges and coastal erosion. To illustrate the journal's even wider brief, there has also been a paper on simulation of oil-slick movements.

The 400 pages of the first volume include 24 articles varying between eight and 22 pages in length. The remainder of the volume is taken up by a valuable "Chronicle" that previews forthcoming conferences, book reviews, a list of recent publications and a correspondence section. The quality of the contributions, though uneven, is acceptable and in general the journal design and production create a favourable impression

The same cannot be said, however, for the quality of the cartographic material. There is a woeful inconsistency of style and worrying variation in the legibility of the diagrams; there is no place for free-hand lettering and graphics in an international journal launched at the end of the 1980s. □

All about a continent

Stephen Moorbath

Journal of South American Earth Sciences. Executive editors Carlos E. Macellari and Norman J. Snelling. *Pergamon. 4/yr. DM190.*

On principle, I have been sceptical about the recent proliferation of regional Earth-sciences journals. It seemed rather old-fashioned to break the Earth sciences up into separate regions rather than separate disciplines, as most conventional journals do. Yet, faced with *Journal of South American Earth Sciences*, I have had second thoughts. Why should one not apply the full panoply of modern Earth-sciences techniques and disciplines to a major geographical sector of the Earth's crust in which most known geological environments are so splendidly represented? It might provide an orderly, manageable approach, both from scientific and editorial viewpoints.

Inspection of the four issues of Vol. 1 (1988) of this well-produced large-format journal dispelled the notion that it was simply a decent burial ground for descriptive papers on regional geology in the old style. It genuinely deals with all branches of modern Earth sciences as applied to South America (as well as Central America, the Caribbean and the Antarctic Peninsula). It covers the entire range of igneous, metamorphic and sedimentary environments from Archaean to the present, as exemplified by Precambrian cratons, mobile belts, sedimentary basins, young arcs and Quaternary rocks, all of which abound in South America. In addition, economic geology is represented by papers on ores and hydrocarbons — there have not been many such contributions in Vol. 1, but no doubt there will be more in the future.

The authorship of the 32 papers in the first volume is truly international, including well-known researchers from economically developed countries working in close collaboration with members of some of the principal university departments and geological survey organizations of South America, where the Earth sciences are taken very seriously indeed.

As well as full-scale scientific papers, the journal publishes short notes, discussions and book reviews, as well as relevant conference and workshop reports. Summaries of new developments in already established regional projects, as well as new initiatives dealing with the geology of the continent, will be summarized and presented on a regular basis The main language used is English; papers in Spanish are acceptable, although there have been none in the first four issues. Abstracts appear in English and Spanish.

Altogether, then, the overall quality is high and the journal will be an important reference for all workers interested and engaged in, or embarking upon, geological research of any kind in South America and surrounding regions. Shrinking library resources may threaten its existence, which will also depend on maintaining and improving the already promising quality and range shown by papers in the first volume. But it deserves to succeed, and I hope that it and other regional Earth-sciences journals can establish a viable foothold. □

Stephen Moorbath is in the Department of Earth Sciences, University of Oxford, Parks Road, Oxford, OX1 3PR, UK.

Them and us

Juliet Clutton-Brock

Anthrozoös: A Multidisciplinary Journal on the Interactions of People, Animals, and Environment. Editor Andrew N. Rowan. *University Press of New England. 4/yr. US$50, elsewhere $60 (institutional); US $40, elsewhere $50 (personal).*

The aims of *Anthrozoös*, which was launched in 1987 by the Delta Society, are to promote multidisciplinary studies on the interactions of people, animals and the environment. Articles in the journal cover subjects as diverse as ethology, psychology, veterinary medicine, archaeozoology, anthropology, and linguistics.

Although one of the most anciently observed characteristics of human beings is their ability to interact with other species, the study of these affiliations is still generally perceived as a peripheral subject for scientific research. The need for people to have animals as companions, particularly in large cities, may be passively accepted by those in authority but there is little realization of the integral role played by pets in society. For example, it is still considered 'neurotic' for a lonely person to grieve over the loss or death of an animal. Similarly, the health benefits that accompany the keeping of pets are largely ignored by the medical profession and those who look after the elderly and disabled.

The intention of *Anthrozoös* is to draw together the scattered publications in this field and to provide scholarly and informed articles on all aspects of animals and human society. The first paper, by R. Lockwood and K. Rindy, in Vol. 1 No. 1, was an analysis of the controversy on the breeding of pit bull terriers, the aggressive natures of which are becoming an increasing danger. Many other socially important articles have been published in the succeeding issues, dealing with topics as varied as equine behaviour problems (K. A. Houpt), zoos today and tomorrow (M. H. Robinson), and an evaluation of a pet programme in prison (A. Katcher, A. M. Beck and D. Levine).

It perhaps requires less intellectual courage to launch a journal such as this in the United States than it would in many other countries where there is still a certain inhibition about studies that can be labelled 'sentimental' or 'anthropomorphic'. But the time is right for a new, scientifically rigorous approach to understanding the many facets of human associations with animals and this new journal provides a professional focus for publication of the results. Such a wide-ranging journal would be improved, however, by a greater international input, and the European editor and members of the editorial board from countries outside the United States should work to achieve this.

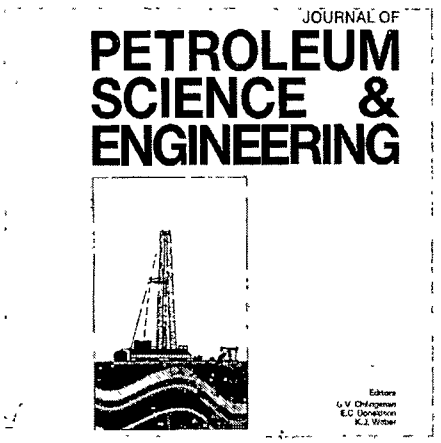
Anthrozoos contains a balanced combination of refereed papers, comments, reviews, letters and reports of meetings. The journal is expertly produced, and the contributions have evidently been carefully edited to be readable and free of jargon. If a wide readership can be established, the journal should lead to a greater understanding of the interactive behaviour of humans and animals and should become a powerful influence in the cause for animal welfare. □

Juliet Clutton-Brock is in the Department of Zoology, British Museum (Natural History), Cromwell Road, London SW7 5BD, UK

Autumn books

The next review supplement to be published in *Nature* will be Autumn books (16 November).

Among the books to be reviewed are *Dangerous Diagnostics: The Social Power of Biological Information* (by Dorothy Nelkin and Laurence Tancredi), *Wonderful Life: The Burgess Shale and the Nature of History* (Stephen Jay Gould), *The Making of Andrei Sakharov* (George Bailey) and *The Mind Has No Sex?* (Londa Schiebinger).



Geophysicists wanted

Andrew S. Mackenzie

Journal of Petroleum Science & Engineering. Editors G.V. Chilingarian, E.C. Donaldson and K.J. Weber. *Elsevier. 8/yr. Dfl.526.*

THE aim of this new journal is "to bridge the gap between petroleum engineering and petroleum geology". The editors have attracted excellent contributions from the different corners of petroleum science, most of which can be understood by laymen with a general knowledge of the oil industry. The articles are published within a year of submission, and Elsevier offer a printing format and standard which is similar to their other Earth-science journals.

In the first issue we learn that the most economic solution for the Prudhoe Bay gas cap is to turn it into alcohol. The previous paper told us that unless the

microbes in waters injected into reservoirs are dissolved with bleach they block the pores of the rock Other issues juxtapose a paper on clay minerals with a theoretical treatment of non-newtonian flow in porous media, and one on limestone porosity with an account of the problems of injecting fluids through highly deviated wells. The most recent of the issues available for review concentrates on enhanced oil recovery.

Although I found the diversity of contributions to be stimulating, I felt that any of the papers could have appeared in more specialist journals: there is little evidence of cross-fertilization as yet. Reading the journal is like eavesdropping on the early stages of one of those parties where the host invites his friends from work and the hostess her friends from work Everyone is introduced at the beginning, then they re-congregate in their original cabals.

The editors have left a crucial set of people off their guest list — the geophysicists. Some difficulties in the exploitation of oil and gas arise because although the engineers' techniques are capable of handling complex descriptions of the rocks between wells, the geologist can deliver only imprecise descriptions. Resolution of this problem is more likely to come from improving the seismic image than from further application of conceptually based geological techniques.

All budding petroleum polymaths should look at this journal. I hope that it will stimulate constructive collaboration (and that the editors will include some geophysics). □

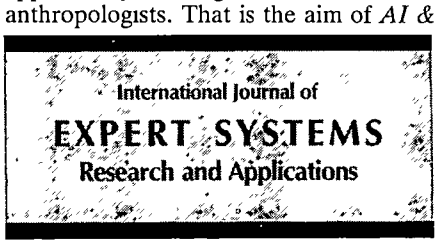
Out of the toy box

Mike Sharples

International Journal of Expert Systems: Research and Applications. Editor-in-chief Mehdi T. Harandi. *JAI, Greenwich, Connecticut, and London. 4/yr. US$135, elsewhere $155 (institutional); US$75, elsewhere $95 (personal).*

AI & Society: The Journal of Human and Machine Intelligence. Editor Karamjit S. Gill. *Springer-Verlag. 4/yr. DM224, $135.*

FIFTEEN years ago Edinburgh University had a robot named Freddy, which consisted of a rotatable arm that could grasp objects placed on a motor-controlled table below it. Cameras gave two views of the table to enable objects to be positioned below the arm. A number of programs were written to demonstrate Freddy's abilities. In one of these demonstrations, toy blocks were scattered on the table and Freddy would locate each block in turn and add it to a stack in the centre of the table Lighting had to be carefully set to avoid spurious reflection, imprecisions in the vision–arm coordination meant that the blocks formed a somewhat disorderly stack, and once it grew to about six blocks high the movement of the table caused the whole stack to tumble over.



Freddy's performance epitomized artificial intelligence (AI) in the early 1970s: a set of rather precarious tricks with toy objects. During that period work was also underway to provide the theoretical foundations to AI, by means of extended logics, simulations of human reasoning and powerful programming tools, but the dream of a 'general problem solver' had been ousted by the hard slog of crafting representations of knowledge to suit each new domain.

Fifteen years on there is still no general problem solver, and AI still has no sound theoretical base, no methods of predicting the behaviour and guaranteeing the reliability of large systems. What occurred in the meantime was the discovery that the same techniques that were used to develop the 'toy' programs of the 1970s could be used to build commercially successful systems for the 1980s. Some tasks, such as the analysis of production problems in fibreglass manufacture, and the medical diagnosis of strokes, can be regarded as bounded problems for which rules can be specified to produce plausible inferences from available data. Such 'expert systems' can provide valuable assistance to human decision making, and the number of commercially deployed expert systems has risen from 50 in 1987 to 1,400 in 1988.

The *International Journal of Expert Systems* serves the growing community of expert-system designers and users. Its editorial board, although drawn mainly from academic institutions, leans markedly towards North America, where most of the commercial applications are to be found. The journal offers rapid publication and consists almost entirely of long papers of good quality and presentation. Without straying too far from the central theme, the first five issues contain articles on natural-language processing, logic programming, inexact reasoning, machine learning and cognitive modelling.

The journal's main limitations are those of expert-systems research in general: there is no guarantee that techniques devised to solve one problem will be of use in another Tasks that are superficially similar may require very different methods of reasoning; it is unlikely that the belief mechanism for the expert system to diagnose faults in fibreglass production will be much use to the developers of the stroke consultant.

Now that AI has become commercially lucrative, and expert systems are appearing in banks, boardrooms and battlefields, the field needs to be subjected to reasoned appraisal by sociologists, economists and anthropologists. That is the aim of *AI & Society*: "to provide a forum for exploring the likely effects of these new technologies, and for debating policy and management issues". The journal is philosophical in approach and European in outlook, with half the advisory board from Britain Several themes have emerged from the first two volumes. the weakness of cognitivism as a foundation for artificial intelligence; the location of computing practice within a culture; the apposition

PROTEIN-NUCLEIC ACID INTERACTION

Volume 10
Topics in Molecular and Structural Biology

Edited by W. Saenger and U. Heinemann.

The book contains articles highlighting the rapidly evolving field of protein-nucleic acid interactions. Individual chapters demonstrate the diversity of biological systems to which protein-nucleic recognition is of central importance.

There are chapters on the interaction of small proteins with DNA and RNA as well as on chromatin organisation. Care has been taken to include accounts of many different experimental approaches to studying the subject. All articles are written by scientists actively involved in the research they describe and conpsidered experts in their respective research areas. The book is well-illustrated and contains extensive bibliographic information to provide easy access to the original literature.

Contents DNA-Protein Interactions in the Regulation of Gene Expression - *P H von Hippel (University of Oregon, Eugene, USA) and O.G Berg (Uppsala University, Sweden)* / Structures of Protein-Nucleic Acid Complexes in Solution by Electro optical Analysis - *D Porschke and J Antosiewicz (Max-Plank Inst, Gottingen, FRG).* / NMR Studies of Protein-DNA Recognition The Interaction of LAC Repressor Headpiece with Repressor DNA - *R Kaptein, R. Boelens and R M J N Lamench (University of Utrecht, Holland)* / The Single-stranded DNA Binding Protein of Eschenchia coli - *J Greipel, C Urbanke and G Maass (Medizinische Hochschule, Hannover, FRG)* / Protein-Nucleic Acid Interaction in Tobacco Mosaic Virus - *G Stubbs (Vanderbilt University, Nashville, USA).* / Structural and Functional Studies of Ribonuclease T1 - *U. Heinemann and U Hahn (Freie Universitat, Berlin, FRG)* / Tet Repressor-Tet Operator Interaction - *W. Hillen and A Wissmann (Inst Mikrobiol and Biochem.,Erlangen, FRG)* / Structure and Condensation of Chromatin -*M H J Koch (DESY, Hamburg, FRG)* / Conclusion / Index

AI & SOCIETY
The Journal of Human and Machine Intelligence

of machine-centred and human-centred technology. Book reviews, news of conferences and recent projects, and an "Open Forum" containing short contributions, provide a variety of form.

Contributors from such diverse backgrounds as anthropology, sociology and theatre ought to make for an interesting and stimulating interchange of ideas, but they lack a common language. The authors cannot use the language of their own discipline, because the readership of *AI & Society* is broad, while the language of AI is too restrictive to embrace its own criticism. The most successful articles are those that offer a focused critique of AI's cognitivism, such as Dreyfus's dismissal of the Socratic assumption that intelligence consists of solving problems by following rules and Pullum's scathing attack on the US Department of Defense's Strategic Computing Initiative (SCI). A major aim of the SCI is to develop autonomous military robots and weapons-control systems. The early prototypes have displayed all the limitations of Freddy the robot; but these AI systems of the 1980s no longer inhabit a toy world. □

Harmony and discord

Robert Temple

International Journal on the Unity of the Sciences: Interdisciplinary Studies of Knowledge and Values. Editor Marcelo Alonso. *International Conference on the Unity of the Sciences, GPO Box 1311, New York, New York 10117 4/yr. North America $25, elsewhere $39.*

Science as Culture. Editor Les Levidow *Free Association Books, 26 Freegrove Road, London N7 9RQ. 4/yr. £35 (institutional); £20 (personal).*

To scientists the sciences are often known for their *dis*unity, so a new journal dealing with interdisciplinary studies is welcome. Despite its clumsy title, *International Journal on the Unity of the Sciences* turns out to be a superior forum for the discussion of questions affecting not only the sciences but society as a whole.

The editors have set themselves a bold agenda and adhere to it with admirable determination. The discourse is at a high level. Figures such as Eugene Wigner, Max Jammer and F.A. von Hayek have contributed articles, which, in general, are intended to combine authoritativeness with accessibility to those outside the particular field under consideration. The journal is proving very successful in meeting this aim. After only a year of publication, it has to my mind become one of the most stimulating of periodicals dealing with science in a wider context.

Here are to be found thought-provoking contributions on issues ranging from *in vitro* fertilization to chaos theory as applied to economics, taking in the world food problem and all manner of ethical and philosophical questions along the way. Many of the ideas and insights are unusual, and the arguments convincing. On the other hand, one must mention the undue number of typographical errors which appear.

Science as Culture is a different matter entirely. Although the proof-reading can't be faulted, the contents can.

The contributors, who seem to be writing largely for themselves with little thought of readers, appear to be drawn exclusively from the ranks of the far left. To them modern science is "moulded by capitalist priorities" (Engels, quoted), and the British Labour Party is dangerously right-wing. Information technology is an instrument of militarists intent on nuclear war; those who support its development

International Journal on the UNITY OF THE SCIENCES
Interdisciplinary Studies of Knowledge and Values

suffer from a "fear of the persecuting breast" (a curious pseudo-freudian idea). Even the history of the piano is viewed from a marxist perspective, though "music almost always manages to escape classification and domination by political interests". Quite so.

Science does indeed need its critics, both for its own benefit and that of society at large. But the mixture of irrationality, intolerance and vituperation to be found in *Science as Culture* serves no purpose. □

NEW FROM CHAPMAN AND HALL IN 1990

Journal of Wilderness Medicine

Editors: Paul S. Auerbach, Vanderbilt University, USA
Oswald Oelz, University of Zurich, Switzerland

In response to an ever-increasing participation by physicians of all specialties in the care and prevention of illness and injuries associated with wilderness environments, the **Journal of Wilderness Medicine** presents original research and clinical reports from scientists and practitioners around the globe. It publishes articles on all aspects of wilderness medicine, including high altitude and climbing, cold and heat-related phenomena, natural environmental disasters, immersion and near-drowning, diving and barotrauma, hazardous plants/animals/insects/marine animals, animal attacks, search and rescue, ethical and legal issues, aeromedical transport, survival physiology, medicine in remote environments, travel medicine and wilderness trauma management.

Editorials, topical reviews, book reviews and letters to the Editors are regular features of **Journal of Wilderness Medicine**, which is published in association with the Wilderness Medical Society.

Quarterly ISSN: 0953-9859 Volume 1 will be published in 1990

Journal of Materials Science • Materials in Electronics

Editor: Arthur Willoughby, University of Southampton, UK

Journal of Materials Science • **Materials in Electronics** is a new refereed quarterly adjunct journal to the Journal of Materials Science which publishes papers on materials and their applications in modern electronics

The Journal covers the ground between the fundamental science, such as semiconductor physics and work concerned solely with applications. It features not only the growth and preparation of new materials, but also their processing, fabrication, bonding and encapsulation, together with the reliability, failure analysis, quality assurance and characterisation related to the whole range of applications in electronics.

It encourages papers in newly developing fields such as low-dimensional structures and devices, optoelectronics including III-V compounds, glasses and linear/non-linear crystal materials and lasers, high Tc superconductors, conducting polymers, thick film materials and new contact technologies, as well as the established electronics device and circuit materials. New preparation methods such as molecular beam epitaxy, MOMBE and chemical vapour deposition techniques, as well as bulk crystal growth are covered, while all aspects of the technology and fabrication of semiconductor devices and circuits, together with their assessment and reliability, will be included. Materials used in more conventional applications such as resistors, inductors, conductors, capacitors, power semiconductor devices, dielectrics, ferroelectrics, insulators and magnetic applications are equally encouraged.

The journal brings together those working on the materials themselves and those concerned with their applications. It therefore provides an important and effective applied research and development forum for a vital area of modern electronics.

Quarterly ISSN: 0957-4522 Volume 1 will be published in 1990

Food Science and Technology Today

Editor: Heather Payne, UK

Food Science and Technology Today is the quarterly information journal of the Institute of Food Science and Technology. It provides a forum for industrial scientists and technologists, researchers, government scientists, public analysts, academics and consultants throughout the world of food science.

The Journal publishes the proceedings of important symposia and meetings on topical issues, informative feature articles, reviews, research topics, submitted papers, letters and news items.

Quarterly ISSN: 0950-9623 Volume 4 will be published in 1990

International Journal of Rehabilitation Research

Editor: Paul Cornes, University of Edinburgh, UK

The **International Journal of Rehabilitation Research** is a quarterly, peer-reviewed, interdisciplinary forum for publication of research into disability and handicap experienced by persons of all ages in both developed and developing societies. Its readership includes researchers, practitioners and administrators in such fields as rehabilitation medicine, nursing, social and vocational rehabilitation, special education, social policy, social work and social welfare, sociology, psychology, psychiatry and rehabilitation technology.

Quarterly ISSN: 0342-5282 Volume 13 will be published in 1990

Journal of Intelligent Manufacturing

Editor: Andrew Kusiak, University of Iowa, USA

The **Journal of Intelligent Manufacturing** is a new refereed quarterly which publishes quality papers on applications of artificial intelligence in manufacturing. It will inform readers on the effective design, construction and use of intelligent manufacturing systems.

The Journal features new methodologies, developments, case studies, surveys and tutorials. It acts as a vital link between the research community and practitioners in industry.

The Journal is important reading for those with a common interest in manufacturing and artificial intelligence, but with backgrounds in engineering, management, business, mathematics, decision, cognitive and computer sciences.

The **Journal of Intelligent Manufacturing** provides an important and effective applied research forum for developers of intelligent manufacturing systems.

Quarterly ISSN: 0956-5515 Volume 1 will be published in 1990

Journal of Materials Science • Materials in Medicine

Editor: William Bonfield, Queen Mary College, UK

Journal of Materials Science • **Materials in Medicine** is a new refereed quarterly adjunct journal to the Journal of Materials Science. It publishes papers on the science and technology of biomedical materials and their applications as medical or dental implants, prostheses and devices, and of biological materials.

It has become apparent that progress in this field, particularly in the development of second generation implants and prostheses with an enhanced lifetime in the body, depends on a multi-disciplinary approach, in which the materials contribution is set in the context of the relevant science, engineering and medicine. **Materials in Medicine** publishes a range of topics from the basic underpinning science to clinical applications, around a central theme of materials in medicine and dentistry

The core element of the journal is the structure, properties and applications of natural materials as well as the metals, ceramics, polymers and composites used in orthopaedic, maxillo-facial, cardiovascular, neurological, opthalmic and dental applications Special biomedical topics include cell-biomaterial interactions, biocompatibility, tissue biomechanics, deformation, fracture, creep, fatigue, fracture mechanics, *in vivo* implantation, degradation, X-ray and electron microscope characterisation, surface analysis, metallurgical processing, powder processing, polymer and composite fabrication, prosthesis biomechanics and clinical trials. Consequently **Materials in Medicine** provides a wider coverage of the role of materials in the context of biomedical applications than is possible in the Journal of Materials Science.

Quarterly ISSN. 0957-4530 Volume 1 will be published in 1990

International Journal of Cosmetic Science

Editor: John Blakeway, Roure Bertrand Dupont SA, France

The **International Journal of Cosmetic Science** provides an up-to-date presentation of current scientific research, both pure and applied, in cosmetics, toiletries, perfumery and allied fields. Specific subject areas include: human and animal-testing of skin, hair and oral products, physical chemistry and technology of emulsion of dispersed systems; theory and application of surface-active agents; aerosol technology; new developments in olfactive research and selected aspects of analytical chemistry.

It should be read by practising cosmetic scientists, dermatologists and those microbiologists, pharmacists, chemists and experimental biologists working on products which will come into contact with the human body.

Bimonthly ISSN: 0142-5463 Volume 12 will be published in 1990

NTP
JOURNALS

Radiation Protection Dosimetry (ISSN 0144-8420) – First published 1981. Vols 29, 30, 31, 32 (1990) £286 UK, US $605 outside UK (airmail $75 extra)

The scope of this journal covers all aspects of personnel and environmental dosimetry and monitoring for ionising radiations including biological aspects, physical concepts, external personnel dosimetry and monitoring, internal dosimetry and monitoring, environment and work place monitoring and dosimetry related to protection of patients Animal experiments and ecological sample measurements are not included.

APPLIED HEALTH PHYSICS ABSTRACTS AND NOTES (ISSN 0305-7615) – First published 1974 Vol 16 (1990) £112 UK, US $255 outside UK (airmail $20 extra)

Each annual volume of four quarterly issues contains about 2,000 abstracts covering the world literature, conferences and unpublished reports in all aspects of applied health physics The subject coverage excludes pure research topics on animals unless there is a topical connection with protection of man Management of radioactive waste is excluded except the protection aspects Comprehensive coverage is given to matters relating to the transport of radioactive materials

International Journal of ***Radioactive Materials Transport*** (ISSN 0957-476X) Vol 1 (1990) £75 UK, US $155 outside UK (airmail $20 extra)

Publication of a new international journal will commence in January 1990 The scope covers all aspects of the transport of radioactive materials including regulatory, safety assessments, design, testing, accidents and operating experiences The journal will be the only international journal exclusively devoted to radioactive materials transport and will provide a means of publishing technical papers and technical notes hitherto unavailable in fully refereed specialist technical journal The journal will be of interest to all organisations concerned with transport of radioactive materials, nationally or internationally, including regulators, consignors, carriers, public authorities, environmentalists, emergency planning officers and particularly scientists and engineers concerned with design, development, testing and safety assessment of all forms of packages for the transport of radioactive materials.

ANNOUNCEMENT AND CALL FOR PAPERS

International Journal of **Radioactive Materials Transport**

ISSN 0957-476X

Publication of a new international journal will commence in January 1990. The scope covers all aspects of the transport of radioactive materials including regulatory, safety assessments, design, testing, accidents and operating experiences. The journal will be the only international journal exclusively devoted to radioactive materials transport and will provide a means of publishing technical papers and technical notes hitherto unavailable in a fully refereed specialist technical journal. The journal will be of interest to all organisations concerned with transport of radioactive materials, nationally or internationally, including regulators, consignors, carriers, public authorities, environmentalists, emergency planning officers and particularly scientists and engineers concerned with design, development, testing and safety assessment of all forms of packages for the transport of radioactive materials.

The Editorial Board comprises internationally known scientists and engineers in the field, many of whom are the Competent Authorities in their own countries. The journal will provide an opportunity for peer review of papers relating to the continuing development of the International Atomic Energy Agency's 'Regulations for the Safe Transport of Radioactive Materials'.

The journal will initially be published as one volume of four issues per year and will include regular news items, especially of an international interest. A special section will be included for listing and describing computer codes used for analysis or planning.

You are invited to submit papers for publication to:-

Mr E. P. Goldfinch,
Nuclear Technology Publishing,
P.O. Box No. 7,
Ashford,
Kent.
TN25 4NW
ENGLAND.

Instructions for authors are shown on the reverse of this announcement.

You are further invited to send details of relevant computer codes for listing, including details of how other experts can contact you if the code can be made available, on licence, to other users.

New Journals from Carfax

carfax publishing company

Carfax Publishing Company
P.O. Box 25, Abingdon,
Oxfordshire OX14 3UE,
United Kingdom

AIDS CARE: Psychological and Socio-Medical Aspects of AIDS/HIV
Joint Editors: LORRAINE SHERR and ROBERT BOR
Provides a forum for publishing in one authoritative source research and reports from the many complimentary disciplines involved in the AIDS/HIV field including: Psychology, Sociology, Epidemiology, Social Work, Anthropology, Social Aspects of Medicine, Nursing, Education, Health Education, Law, Administration, Counselling (including various approaches such as behavioural therapy, psychotherapy, family therapy etc.)
1990 – Volume 2, 4 times a year
ISSN 0954–0121 £74.00

CONNECTION SCIENCE: Journal of Neural Computing, Artificial Intelligence and Cognitive Research
Editor: NOEL E. SHARKEY
An interdisciplinary scientific journal covering research in human and artificial intelligence, cognitive science, computational neuroscience and advanced computer science. Articles are published which either address current connectionist issues or employ connectionist techniques.
1990 – Volume 2, 4 times a year
ISSN 0954–0091 £74.00

FOOD AND AGRICULTURAL IMMUNOLOGY
Editor: M. R. A. MORGAN
Presents original immunological research with food, agricultural, environmental and veterinary applications. The primary focus of the journal is on research exploiting antibodies and the immune response with food and agricultural application.
1990 – Volume 2, 4 times a year
ISSN 0954–0105 £70.00

HIGH PERFORMANCE POLYMERS
Editor: DOUG WILSON
Presents original research in high performance polymer science and technology. The journal is primarily applications-driven, with a major focus on the molecular structure/processability/property relationship with regard to the specified applications.
1990 – Volume 2, 4 times a year
ISSN 0954–0083 £88.00

JOURNAL OF HARD MATERIALS
Editors: C. A. BROOKES, J. E. FIELD and R. WARREN
A new journal which meets the need for timely publication of original papers on advances in the understanding of the properties of hard materials in bulk form and as coatings. Priority will be given to papers which aim to explain deformation processes and mechanical and related properties in terms of atomic bonding, crystal structure, microstructure and chemical composition.
1990 – Volume 1, 4 times a year
ISSN 0954–027X £84.00

JOURNAL OF NUTRITIONAL MEDICINE
Editors: STEPHEN DAVIES and DAMIEN DOWNING
The official journal of the British Society for Nutritional Medicine, this new title deals with nutrition and its crucial relationship with clinical medicine. It will present original research and reports of clinical practice in the application of advances in nutritional science to medical treatment
1990 – Volume 1, 4 times a year
ISSN 0955–6664 £84.00

PR people in AI

P.W. Hawkes

International Journal of Pattern Recognition and Artificial Intelligence. Editors-in-charge H. Bunke and P.S.-P. Wang. *World Scientific. 4/yr. $260 (institutional); $138 (personal).*

THERE is no shortage of journals catering for the image-processing and pattern-recognition (PR) community: an IEEE series, the long-established and beautifully produced *Computer Vision Graphics, and Image Processing*, *Pattern Recognition* and *Pattern Recognition Letters*, as well as specialized journals in medical imaging, remote sensing and the like. The list of artificial intelligence (AI) titles is not quite so long, but in neither field did one feel that important papers were piling up unpublished for want of journal space.

There was, however, no title that explicitly united AI and PR, and the object of this new journal is to attract papers in either field or, best of all, papers that involve both. Its success must be judged on this last category, for the remainder are already well catered for

Rather to my surprise, there are a number of applied papers that do justify the existence of this new serial in the sense that they would otherwise have been published in journals so specialized that the PR and AI communities would probably have remained unaware of them. A good example is the contribution by H. Freeman and J. Ahn "On the Problem of Placing Names in a Geographic Map", a "seemingly simple task [that] is, in fact, remarkably subtle and complex". This is a fascinating article, with much to interest the student of image analysis, which no doubt would otherwise have appeared in *The American Cartographer* or *Annuaire International de Cartographie*.

Another vivid example is "Vision Applications in the Fishing and Fish Product Industries" by H. Arnarson, K. Bengoetxea and L.F. Pau, which tells us how machine vision can be used to detect worms (in cod...), bone residues and 'aesthetic' defects and also to sort different species despite the hostility of the shipboard environment. Here too, a glance at the list of references takes us outside the usual PR and AI territory with *Austral. Fish. J., Prog. Fish. Cult.* and *J. Food Protection* among others.

A quotation will show why such a paper is of interest to those involved in pattern recognition: "sorting by species as well as precise length estimation involves hypothesizing head and tail locations ... the filter kernels [for morphological filtering] . . must be size independent but species dependent The shape anomalies [sic] between male and female fish as well as unretracted fins ... offer interesting challenges". Nevertheless, such papers as these are a small minority in the numbers I have seen, two of which contain conference proceedings (the Eighth International Conference on Pattern Recognition, held in Paris in 1986, and the International Workshop on Expert Systems, Novosibirsk, 1987).

The journal is well produced on glossy paper, accepts colour artwork and appears willing to print long articles Publication times range from eight months to over a year and there are no page charges. The personal subscription rate does not seem excessive, unlike the inflated institutional rate. If the *International Journal of Pattern Recognition and Artificial Intelligence* is not indispensable, nor is it otiose — and if you cannot afford it, it is covered in *Current Contents*. □

P.W Hawkes is in the Laboratoire d'Optique Electronique du CNRS, BP 4347, F-31055, Toulouse Cedex, France

Infant wisdom

G.F.J. Garlick

Physics World. Editor Philip Campbell. *Institute of Physics. 12/yr. UK and elsewhere £53, North America $104 (institutional); UK £23, North America $44, elsewhere £25 (personal).*

PHYSICS WORLD, an amalgamation and extension of two previous Institute of Physics' publications, began its monthly appearance in October of last year and is designed to present the interests of physics as a profession. The contents are wide ranging, running from the current problems of physics at all levels of education, through fiscal matters such as salaries and funding, to the interaction of British physicists with their counterparts in Europe and elsewhere, and reviews of the science itself.

To quote from the first editorial, the journal appeared "at a pivotal moment for physics, and in the long term, technological exploitation in the UK". Several issues subsequently describe the turmoil caused by new schools' curricula proposals from the Department of Education and Science, the critical-size test for university physics departments of the Edwards Committee and the faltering steps of the British government over continued support for CERN and high-energy physics. Again quoting the editor, "perhaps *Physics World* can be granted the privilege of the new born to express outrage at a hostile environment".

On a more positive note, most of the contents are devoted to review articles, both brief and extended. These generally deal with the frontiers of physics, or are sometimes historical, and all are written to avoid mathematical presentation (no mean feat given some of the topics). The standard is high and the publishers are to be commended in maintaining it over so many issues. Titles are sometimes snappy — "Quark Soup for Starters" or "Is Gravity as Simple as We Thought?" — but one does get in-depth treatment. Topical issues such as 'cold fusion' have been discussed soberly, much attention being paid to the weighing of claims against the evidence. A different but very satisfying combination was seen in the April 1989 issue, which was largely devoted to "Physics in Scotland". The range and intensity of physics activity there was certainly a revelation to me.

Physics and the activities of physicists need to be explained to a public which often sees only the menace of nuclear waste and weapons, and fails to realize how every corner of life is filled with the products of physics. This new publication will be a valuable medium for communication of this kind. There have already been articles on "Communications Breakdown in Nuclear Energy" and "Nuclear Power is Green Power" which make a significant contribution in this respect.

The section of *Physics World* that always occupies the last page of text is entitled "Lateral Thoughts". This is the Parthian shot, where levity is introduced.

The topics form delightful light reading and apparently are most popular among physics student finalists, who have received free copies during the last academic session. I hope they didn't skip too many of the pages to get to them. Particularly to be commended are the book reviews, which show just what can be achieved in this medium.

Each issue contains plenty of news about the Institute of Physics and its members, and you can also look for jobs or supplies of apparatus in the classified section. Finally, cost — for members, *Physics World* is especially cheap, but it is not at all exorbitant for libraries and others. □

G.F.J Garlick, is at 267 South Beloit Avenue, Los Angeles, California 90049, USA.

Dynamic model

John Guckenheimer

Nonlinearity. Honorary editors J.D. Gibbon and D.A. Rand. *Institute of Physics and London Mathematical Society. 4/yr. UK £178, North America $338. In the United States distributed by the American Institute of Physics.*

THE joint sponsorship of *Nonlinearity* (by the London Mathematical Society and the Institute of Physics) is unusual and it bespeaks the vitality of research on 'nonlinear' phenomena. The journal has already found itself a niche and it will undoubtedly persist as a publication of high quality. Its editorial board is strong and large enough to cover well the topics within its mandate — "nonlinear mathematics, mathematical and experimental physics and other areas in the sciences where nonlinear phenomena are of fundamental importance".

As the complement of all things linear, nonlinearity hardly seems a cohesive discipline. Nonetheless, there is a diverse group of scientists and mathematicians with overlapping interests in the phenomena concerned. This group of people forms the constituency of the new journal, as well as of several others that have slightly different emphases, and their work gives form to the subject. Among the topics of papers printed in the first few issues of *Nonlinearity* are chaos, fractals, nonlinear partial differential equations, dynamical systems, solitons, singularities and twistors.

The centre of gravity of *Nonlinearity* is distinctly different to that of such related journals as *Physica D*, *Ergodic Theory and Dynamical Systems*, *Communications of Mathematical Physics*, *Journal of Statistical Physics* and *Journal of Differential Equations*. *Physica D* is very similar in spirit to *Nonlinearity*, but its emphasis is decidedly more on physical aspects. On the other hand, *Ergodic Theory and Dynamical Systems* and *Journal of Differential Equations* are mathematics journals that frown on publishing papers that do not meet strict standards of mathematical rigour. In *Communications of Mathematical Physics* and the *Journal of Statistical Physics*, there is more emphasis upon models of statistical physics and field theories.

In *Nonlinearity* the stress is on dynamical systems theory. Over half of the papers published to date deal with the subject. There is a tremendous variation in the style of work in this area. At one end of the spectrum is pure mathematics with its insistence upon rigour, and at the other end is routine analysis of dynamical models that arise in many areas of science. The role of numerical studies and of theory that is founded upon careful numerical study rather than rigorous proof has been a source of tension within the field. Although *Nonlinearity* includes many papers that would fit comfortably in other mathematical journals, it also serves the community of workers who rely upon computers. The blend of rigour and computationally justified theory found in *Nonlinearity* is refreshing, and I hope that it represents a trend that will spread to more areas of mathematics. □

John Guckenheimer is in the Departments of Mathematics and Theoretical and Applied Mechanics, Cornell University, Ithaca, New York 14853, USA

Chase for the holy grail

John Ruvalds

Physica C: Superconductivity. Editors M. B. Brodsky, G. W. Crabtree, B. D. Dunlap, R. P. Griessen, S Maekawa, Yu. A. Osipyan, H. R. Ott and S. Tanaka. *North-Holland. 24/yr. Dfl.3,370.*

Journal of Superconductivity. Co-editors Donald U. Gubser and Stuart A. Wolf. *Plenum. 4/yr. North America $135, elsewhere $160 (institutional).*

International Journal of Modern Physics B. Edited by the editorial board. *World Scientific. 16/yr. $485 (institutional); $237 (personal).*

Modern Physics Letters B. Edited by the editorial board. *World Scientific. 22/yr. $475 (institutional); $234 (personal).*

Superconductor Science and Technology. Honorary editor J. E. Evetts. *Institute of Physics. 12/yr. £120, $228.*

EVER since the 1986 discovery of high-temperature superconductivity in an unlikely group of copper oxides, the race to find new materials with zero resistance to the flow of electrical current has generated immense excitement in the scientific community. The ultimate quest of a room-temperature superconductor has captivated thousands of chemists, physicists and a variety of other scientifically interested parties.

In addition to the intellectual challenge of understanding how the new superconductors function, the aura of a scientific 'breakthrough' and the promise of a new technology with imaginative commercial applications have attracted considerable interest among the general public, industrial representatives and even government officials. The dissemination of information in the field is thus beset by diverse demands.

The deluge of scientific data on the new superconductors has already surpassed 4,600 publications in a mere two years, and there is no sign of relief. Despite progress in the growth of single crystal samples and a vast array of confirmed experimental features, the origin of the superconducting properties at high temperatures remains a mystery. Surprisingly, there is not even agreement on the nature of the charge carriers in the copper oxides. Holes, electrons and more exotic species have been proposed as viable candidates, but the crucial ingredient remains elusive. Then there is the dilemma of the ideal number of carriers needed to achieve superconductivity at the highest possible temperature, and the embarrasing existence of analogous cuprate compounds which do not become superconducting at all.

On the optimistic side, there now appear to be no crippling theoretical obstacles to superconductivity at room temperature, even though this dream was regarded as a fantasy only a few years ago. Of course, the lack of a definite mechanism for the cuprates does not constrain the enthusiasm and imagination of many researchers in the field.

To cope with the spectacular growth in the literature, many established journals have revised their refereeing procedures, putting the emphasis on rapid publication of novel results. The need for new specialist journals may thus be limited to filling a gap in the established coverage.

The new journal *Physica C. Superconductivity* is derived from the highly regarded *Physica*, which has a long tradition of publishing first-rate articles in the physical sciences. The editorial board is composed of international experts who are actively engaged in basic research in the field. The early issues are notable for breadth in coverage and overall high calibre of the scientific content. Theoretical contributions range from the fundamental issue of casuality and the Josephson effect to a variety of computer calculations of electronic structures in specific materials. Several papers proposing innovative mechanisms for superconductivity have also appeared.

Experimental results published in *Physica C* include original findings on chemical substitutions which influence the transition temperature of the cuprate superconductors. Excellent articles on data for the heat capacity, transport properties, neutron scattering, nuclear spin resonance, critical magnetic fields, and microstructure characterization of samples attest to the high standard of this journal, which belongs in any library serving the basic research needs of scientists.

The *Journal of Superconductivity* aims to provide a new "forum for the publication of high-quality original articles on *all* aspects of the Science and Technology of Superconductivity". This ambitious goal has not been fully met in the first issues, but nevertheless there have been some interesting speciality features which may

mean the journal will fill a niche in a crowded field For example Vol. 2, No. 1 consists of a superb bibliography of thousands of references compiled from a Westinghouse database. The index to keywords, authors, subjects and chemical element compositions is especially informative and useful. This source, in accessible, compact journal form, may well justify the cost of a trial subscription.

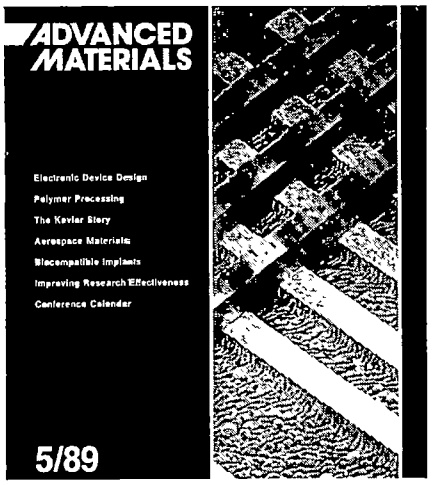
Featured articles in *Journal of Superconductivity* have included an outstanding, comprehensive review of heat-capacity measurements on cuprate compounds, and discussions of some technological applications. Contributions on magnetohydrodynamic ship propulsion, circuits, electron accelerators, logic devices and power applications are pitched at an introductory level, and should appeal to those involved in technology The papers on sample growth and processing, with their exquisite colour photographs, exemplify the high quality of production. On average, the articles are brief and the first few issues do not pose a dire threat to library shelf space.

A committee of 39 distinguished scientists edits the *International Journal of Modern Physics B,* which covers condensed matter, statistical and applied physics. Another 28 experts oversee the section "Rapid Communications in High T_c Superconductivity". A broad geographical distribution of authors from Australia, Bahrain, Belgium, Brazil, Bulgaria and 19 other countries is evident in the handful of journals made available for review. In a similar vein, the supplement *Modern Physics Letters B* includes rapid communications and a section of "Brief Reviews" which exhibits short (typically three-page), less-technical summaries of select specialities

Materials microfaults are the mainstay topic for *Superconductor Science & Technology.* Grain boundaries, oxygen defects and other imperfections need to be overcome for large-scale technology, and contributors examine the detailed morphology of samples in view of their influence on critical currents and other properties. Research on film-preparation techniques is neatly presented, with a critical examination of the prospects of the near-term applications in microwave detection and other signal-processing devices.

As the field matures, the emphasis on haste should yield to traditional values. It is a pleasure to find some interesting articles in all of the journals reviewed here. But their future success will be determined by the careful enforcement of standards, as well as by the setting of goals that complement rather than compete with those of established journals.

John Ruvalds is in the Department of Physics, University of Virginia, Charlottesville, Virginia 22901, USA.



Communicating in a new era

Alan Windle

Materials Science and Engineering B: Solid-State Materials for Advanced Technology. Editors M. Balkanski, K Kamimura and S. Mahajan *Elsevier Sequoia 12/yr. SwFr.840.*

Advanced Materials. Editor Peter Golitz. *VCH. 12/yr. DM 298, £115, $190 (institutional); DM 98, £42, $79 (personal).*

Materials Science and Engineering B: Solid-State Materials for Advanced Technology was launched in August last year. If it hadn't been for the advent of high-T_c superconductivity, one wonders whether the publishers would have dared — a new

journal, in an otherwise fairly mature field which is already quite well provided for, is a risky venture

Yet there is a clear professionalism about *Solid-State Materials.* It is a traditional, even classy, publication. One can play the name game, and try to guess its contents from the title, or perhaps from the editorial statement of scope inside the front cover. A better guide is the papers it has attracted to date, which deal almost exclusively with inorganic materials and concentrate most frequently on the relationship between structure and electronic properties. There is a good blend of well-established solid-state physics and solid-state chemistry, bound together by contributions which focus on the production of optical and electronic materials. The journal also provides a most appropriate environment for the 20 per cent or so of its papers which deal with the new superconductivity.

Authors seem to be treated well. The time between acceptance of papers and publication is averaging around six months, and there is every indication that this performance will be maintained. The quality of the reproduction of diagrams is high, and the micrographs come across adequately, although they are usually disciplined into single columns where their comparatively small size means that they lack impact, if not clarity. There are also 25 reprints for free.

For 1989, the journal bills itself as a quarterly, although one can but puzzle over the numbering system. The rather thin issue of December 1988 is designated 3–4, whereas the first to appear this year (devoted to the proceedings of a conference on deep implants) was numbered 1–3, which meant that number 4 appeared in April! Indeed, the slightly bizarre numbering is associated with a lack of uniformity both in publication dates and the thickness of the offering. Of course this may settle with time, and any confusion will tend to be reduced on binding.

Here we have a solid and respectable journal.

Advanced Materials is a different type of publication altogether. It is a monthly, aimed at the materials scientist, whose subject has grown and diversified so dramatically over the past ten years. Although it is possible to be an expert in one corner of the discipline, there is the perennial need to remain informed across the whole field, and a need too to foster a professional identity. If journals are to unify materials research rather than segregate it into subdisciplines, they must somehow represent the various components without becoming unwieldy.

Advanced Materials seems to have found this niche. It is a heady mixture of essays, review and research communications, news and conference data, and it works admirably. The emphasis is on new materials, and there is a fair balance across the component subjects of metallurgy, ceramics, composites and polymers. It is perhaps the journal one would most like to have delivered to a busy desk — the articles can be read in a few minutes, yet they communicate at the highest level and reflect the perception of their often-distinguished authors. One can of course quibble at the presentation; the paper used is too thin, for example, the print showing through from the other side of each page.

There is currently some basic rethinking, among materials scientists at least, as to how research should best be published, and the German community is among the leaders in this respect. We may be seeing the end of the traditional research paper, which could be superseded by a combination of rapid communication of results from laboratory to print with periodic state-of-the-art reviews. *Advanced Materials* is a part of this new era, and that is perhaps the underlying reason why it is exciting. □

Alan Windle is in the Department of Materials Science and Metallurgy, University of Cambridge, Pembroke Street, Cambridge CB2 3QZ, UK.

On the third branch

Colin Upstill

Computers in Physics. Editor Robert R. Borchers. *American Institute of Physics. 6/yr. US $125, Canada and South America $135, elsewhere $140 (institutional); US $25, Canada and South America $35, elsewhere $40 (individual).*

In the distant past, physics was thought of as a branch of philosophy, and the behaviour of the physical world was understood purely by theorizing about it. The computerization of physics today is a revolution of similar magnitude to the experimentalization of physics that took place around the time of Galileo. In the history of physics, the 1980s will be remembered neither for high-temperature superconductivity, nor for cold fusion, but as the decade in which computers really entered the methodology of physics.

Computers in Physics is an interdisciplinary periodical based on the recognition that a third branch of science is rapidly developing. It also tries to combine learned journal with magazine, juxtaposing peer-reviewed archival papers with news, views and feature articles. Most of the latter are excellent, but the quality of the research papers is less certain: some are introductory, some expository, and few contain much that is really novel.

The range is vast. In early issues, subjects dealt with include expert systems, computer algebra, supercomputer algorithms, particle physics codes, colour vision, the fractal dimension of cerebral surfaces, seismic tomography, computer architectures, parallel processing (highly relevant, as so much computing in physics needs supercomputer performance), optical computing, neural networks, the physical limits of computing (physics is as unavoidable within the machines as the machines are in physics), and software construction methods. It is especially good to see coverage of this last topic — unlike chemists, physicists tend to write their own code, and are usually self-taught, with bad or even dangerous habits.

After an initial hiccup — there is but one paper, six pages long, in the 96 pages of the third issue — *Computers in Physics* has settled down to being almost exactly half magazine and half journal. There are regular columns on numerical recipes, simulations, computers in physics education and spreadsheets. Spreadsheets can be used for purposes far beyond their original applications in accounting, and offer a remarkable capability for quick and easy solutions to a broad range of scientific problems; sharp instruments cut both ways, however, and these programs can provide the unwary with pretty collections of incorrect answers.

There is a fair amount that is good about *Computers in Physics*, and much that is mixed. The papers have lots of program listings in them, but many lines are irrelevant to the technical content of the paper; language-independent pseudocode or flow diagrams are far better, and happily these have started to appear in the most recent issues. Colour is heavily used, but in the journal section it is largely negated by complicated pictures being reproduced at the size of postage stamps.

The articles and papers have a reasonably international authorship, though with a decided US bias which is both understandable and acceptable. Yet apart from a couple of brief references to parallel-processing activities in Europe and to Japanese supercomputers (and in terms which imply 'the threat from'), the news pages are almost entirely US-orientated. In consequence the international appeal is considerably diminished, as is the value of the periodical to its US readers. Another failing is that there is no obvious distinction between the magazine and journal pages. To be concerned at this is not élitism — the boundary conditions on an author are different for magazine articles and for peer-reviewed papers, and the extent to which another researcher can rely on each varies accordingly.

Communications of the ACM, *Computer* and *IEEE Software* have most of the good points of *Computers in Physics*, such as colour illustrations, and cover between them its computing aspects. With *American Journal of Physics* or *European Journal of Physics* for more pedagogical papers, and the established physics literature for specific applications, the considerable range of *Computers in Physics* is already well catered for. The question is whether or not it is worthwhile to have such diverse material in one place. I rather doubt it. □

Colin Upstill is with Plessey Research, Roke Manor, Romsey, SO51 0ZN, UK.

Also submitted for review

The following list shows the journals that were eligible for review but that are not covered in the preceding pages. It does not include those titles that had not published enough issues to be considered (see page 350).

Acta Geologica Sinica (Geological Publishing House, Beijing, distributed by Pergamon).

Acta Meteorologica Sinica (China Meteorological Press, Beijing, distributed by Pergamon).

American Journal of Hypertension: Journal of the American Society of Hypertension (Elsevier).

APMIS (formerly *Acta Pathologica, Microbiologica et Immunologica Scandinavica*) (Munksgaard, Copenhagen).

Australian Systematic Botany (CSIRO/Australian Academy of Science, East Melbourne, Victoria).

Cellular Signalling (Pergamon).

Chinese Journal of Atmospheric Sciences (Allerton, New York).

Chinese Journal of Infrared and Millimeter Waves (Allerton, New York).

Clinical Microbiology Reviews (American Society for Microbiology).

Experimental Thermal and Fluid Science. International Journal of Experimental Heat Transfer, Thermodynamics, and Fluid Mechanics (Elsevier).

International Journal of Numerical Modelling: Electronic Networks, Devices and Fields (Wiley).

Journal of Planar Chromatography — Modern TLC (Hüthig).

Journal of Food Composition and Analysis: An Official Publication of the United Nations University International Network of Food Data Systems (Academic).

Journal of Human Nutrition and Dietetics: The Official Journal of the British Dietetic Association (Blackwell Scientific).

The Journal of Trace Elements in Experimental Medicine (Alan R. Liss).

Microbial Ecology in Health and Disease (Wiley).

Microwave and Optical Technology Letters (Wiley).

Muon Catalyzed Fusion: Journal Devoted to Theory and Experiment in μCF and Its Applications, Mesic Atomic and Molecular Physics (Baltzer, Basel).

The National Medical Journal of India (All India Institute of Medical Sciences, New Delhi/Oxford University Press).

Nuclear Geophysics: A Journal of Nuclear Techniques in the Earth and Environmental Sciences, Minerals Exploration, Mining and Process Control (Pergamon).

Pigment Cell Research (Alan R. Liss).

Reproductive and Genetic Engineering: Journal of Feminist Analysis (Pergamon).

Reproductive Toxicology (Pergamon).

Resources, Conservation and Recycling (incorporating *Resources and Conservation* and *Conservation and Recycling*) (Elsevier/Pergamon).

Schizophrenia Research: An International Multidisciplinary Journal (Elsevier).

Soviet Journal of Applied Physics. Thermophysics, Heat Transfer, Plasma Physics, Protective Coatings, Fluid Dynamics, Cold Climate Engineering (Scripta Technica, a subsidiary of Wiley).

advanced drug delivery reviews

Editors-in Chief

R.L. Juliano, *Department of Pharmacology, University of North Carolina Medical School, Chapel Hill, NC 27514, U.S.A.*
G. Poste, *Smith Kline and French Laboratories, Philadelphia, PA, U.S.A.*
E. Tomlinson, *Ciba-Geigy Pharmaceuticals, Horsham, West Sussex, U.K.*

Audience

Pharmaceutical scientists, clinical pharmacologists, chemical engineers and biotechnologists.

Advanced Drug Delivery Reviews publishes comprehensive yet critical review articles on current and emerging aspects of research into the design and development of advanced drug delivery systems and their application to experimental and clinical therapeutics.

Articles review the current status of a specific topic giving equal emphasis to:

- **the identification of the major problems** that must be solved to allow further successful development,
- **evaluation of shortcomings** in current conceptual and technical approaches and,
- **discussion of possible solutions** to these difficulties.

The scope of the journal is broad and does not focus exclusively on particular delivery systems or target diseases.

Advanced Drug Delivery Reviews is an authoritative forum for the critical analysis of research efforts across the entire spectrum of current investigations in advanced drug delivery systems and their applications in human and veterinary medicine and in agriculture.

TAKE NOTE OF OUR NEW JOURNALS

Churchill Livingstone **PRESCRIBES SUCCESS**

CURRENT ANAESTHESIA AND CRITICAL CARE

Editor: B J Pollard

An international review journal devoted to the current practice of anaesthesia and critical care. Covers the entire postgraduate syllabus over a three-year period. Topics covered include Medicine, Physics and Monitoring, Pharmacology, Practical Procedures and Equipment. Essential reading for qualified and trainee anaesthetists at all stages in their career.
Quarterly publication.
First issue September 1989

GULLET

Editors: J R Bennett and G G Jamieson

Will publish papers on all aspects of disorders of the oesophagus—their aetiology, investigation and diagnosis as well as medical and surgical treatment. **Gullet** will provide a single forum of material to keep research workers and clinicians up-to-date with the latest developments in their field.
Quarterly publication.
First issue September 1990.

LITHIUM

Editor: F N Johnson

Will publish selected high quality articles on all biomedical aspects of lithium i.e. biochemical, physiological, pharmacological, psycho-pharmacological, and clinical. **Lithium** will provide a single outlet for these varied research themes and so unify the subject of lithium research and therapy.
Quarterly publication.
First issue March 1990

PLATELETS

Editor-in-chief: S Heptinstall

The only journal devoted to platelet-related research. Contains original and review articles on vascular disease, cerebral and myocardial ischaemia, asthma, platelet biochemistry, growth factors, platelet immunology, platelet transfusion therapy, comparison with other cells, basic pharmacology and clinical trials of anti-platelet agents.
Quarterly publication.
First issue March 1990

REVIEWS IN MEDICAL MICROBIOLOGY

Editor: R J Williams

Internationally acknowleged experts world-wide will provide reviews of topics in medical microbiology, virology, mycology, parasitology, clinical microbiology and hospital infection. Contents of the first issue will include Chlamydia, Virus Infections in Children with Cancer, Quinolones and Molecular Epidemiology of Epidemic Meningitis.
Quarterly publication.
First issue January 1990.

THE PERFECT BIND

When did Nature cover Science in Switzerland?

Where are the latest research results about AIDS?

What's the latest development in superconductivity?

Have you noticed that you never manage to lay your hands on that issue of Nature when you need it most!

For a very reasonable cost, why don't you save time and effort by investing in a set of smart and durable Nature binders

	Single binder	Set of 4	
UK	£5.25	£16 00	Prices include
Rest of World	£7 75	£22.00	postage and packing

Never again will you be at a loss for that vital information. Each binder holds approximately 16 issues and makes sure that key knowledge is kept at your fingertips.

Complete the order form and in no time your copies of Nature can be kept in order.

Please send me_____ Nature binders

☐ I enclose a cheque for £_____ made payable to Nature

☐ Please charge my credit card for £_____
☐ Visa ☐ AMEX ☐ Access
☐ Diners Club

Restorative Neurology and Neuroscience

Editor-in-Chief: **D.G. Stein,** *Restorative Neurology and Neuroscience, The Graduate School, State University of New Jersey, Rutgers, Hill Hall, Newark, NJ 07102, U.S.A.*

Scope and Purpose: Papers relating the plasticity and response of the nervous system to accidental or experimental injuries or interventions, transplantation, neurodegenerative disorders, and experimental strategies to improve regeneration or functional recovery will be considered for publication. Experimental and clinical research papers adopting fresh conceptual approaches are encouraged. The overriding criteria for publication are novelty, significant experimental or clinical relevance, and interest to a multidisciplinary audience.

Types of Papers:
* **Full-length Papers:** giving findings of original basic or clinical research in any area of restorative neurology and neuroscience within the scope of the journal. These papers will be published within four to six months of acceptance.

* **Short Communications:** such as brief reports of research results which have reached a stage where they are ready for preliminary communication. Short communications will be published in the next available issue, usually within 3 months. They should not be more than 1500 words, or equivalent space, including tables and figures.

* **Review Articles:** on specialised topics within the scope of the journal. Prospective authors should contact the Editor-in-Chief beforehand.

Manuscripts, in the English language only, should be submitted *in quadruplicate* to the Editor-in-Chief, **Dr. D.G. Stein,** at the address shown above.

Subscription Information:
1989/90: Volume 1 (1 volume in 6 issues)
Price: US $165.25/Dfl. 360.00
plus US $12.00/Dfl. 26.00 postage and handling
ISSN: 0922-6028 *The Dutch Guilder price is definitive.*

1990: Volume 2 (1 volume in 6 issues)
Price: US $ 174.50/Dfl.380.00
plus US $ 13.00/Dfl. 28.00 postage and handling
A personal rate is available on request from the Publisher

Ask for a sample copy now!

Discussions in Neuroscience

Now published by **Elsevier Science Publishers** for the Foundation for the Study of the Nervous System (FESN)

Series Editor: **Pierre J. Magistretti,** *University of Lausanne.*

* high quality monographs and edited proceedings on the most topical areas in neuroscience
* the very latest developments and research progress in neuroscience, carefully edited into a pleasant, readable form
* of invaluable interest to neuroscientists, neurologists, physicians, in addition to researchers, students and non-specialists whose primary research interests are outside the field of neuroscience
* written by leading neuroscientists; headed by a distinguished Advisory Board
* illustrations of excellent quality and clarity (often in full colour)
* the only review/monograph journal in the field with this broad appeal

Subscription Information:
1989: (4 issues per year) Price: Dfl.60.00/US $30.00 including postage and handling
*The US $ price is definitive. Individual copies can be purchased separately and examination copies are available for possible adoption for course use - **please write for further details.***

Cost Versus Benefit in Cancer Care

Edited by Basil Stoll, Honorary Consultant, St Thomas' Hospital, London

In view of spiralling health costs in Western countries, physicians on both sides of the Atlantic must reach agreement on what is 'appropriate' treatment for patients with advanced cancer This book is the first to expose the dilemma between cost and benefit in the treatment of advanced cancer, It is written for physicians, who ultimately have to make the choices in allocating resources, and discusses frankly the reasons for differences in treatment across the Atlantic

Contents Introduction G Mooney PART 1 CURRENT DILEMMAS What is Overtreatment in Cancer? B A Stoll What is Best for the Patient? United States View A U Buzdan What is Best for the Patient? Clinical Cancer Monographs

Clinical Cancer Monographs is a new series presenting the data compiled by the English West Midlands Regional Cancer Registry, by site of malignancy. The unique feature of the series is the presentation and analysis of data not just on incidence, but also on treatments and the effect of treatments on survival. The records used in the analysis cover a 25 year period and a population of 5 million people, with demographic characteristics which serve as a useful model for other regions in industrialized countries The series will be of great value to oncologists and clinicians as well as health planners and medical statisticians

Peptide and Amino Acid Transport Mechanisms in the Central Nervous System

Edited by L Rakic, Professor of Neurobiology and Biochemistry, Belgrade Clinical Centre; David J Begley, Lecturer, Department of Physiology, King's College London; Hugh Davson, Professor of Physiology, St Thomas Hospital, London and Berislav, Associate Professor, Belgrade University Institute of Medical Physiology

The way in which the brain regulates its internal environment separately and distinctly from the rest of the body has long generated intense interest and debate. Today, advances are being made at an ever accelerating rate. This volume addresses itself to regulation, within the brain extracelluar fluid, of peptide and amino acid levels, particulary those which are known or putative neurotransmitters and neuromodulators. Particular attention is also devoted to the way in which peptides may penetrate the blood-brain barner or alter its permeability to other solutes. This volume is of vital relevance to anyone studying central nervous system disease, especially the fundamental problem of designing drugs and agents which will penetrate the blood-brain barrier and excert central nervous actions. The relevance to mental health and disease is also unquestioned.

Contents: Introduction, H Davson / Neuropeptide Transport Mechanisms in the Central Nervous System, B V Zlokovic et al / Peptides and the Blood-Brain Barrier Penetration and Modulating Influences, W D Banks et al / Structural Aspects of the Blood-Brain and Blood-CFS Barriers with Respect to Peptides and Proteins, K Mollgard / Proteins in CFS of the Developing Brain; N R Saunders & K Dziegiewska / Cyclic Necleotide Mediated Regulation of Albumin Transport in Brain Microvessels, F Joo / Peptides and Cerebral Microvessels, M Spatz / Transport and Barrier Systems of the Cerebral Microvasculature Enzymatic Aspects, B M Duncic & B B Mrsulja / Transport of Insulin at the Blood-Brain and Blood-CFS Barriers, L K Squires & D J Begley / Insulin as a Regulatory Peptide in the CNS, D G Baskin et al / Experimental Psychosis and Transport of Amino Acids and Peptides Across the Blood-Brain Barrier, L.K Rakic et al / Transport of Enkephalins from the Cerebrospinal Fluid of the Rabbit, D J Begley / Control of Opioid Peptide Levels by Peptidases in the CNS, L B Hersh / The Effect of Cyclic AMP and Adenylate Activators on CSF Production, S Hyman et al / Peptide Receptors of the Cerebral Capillary Endothelium and the Transport of Amino Acids Across the Blood-Brain Barrier, A Ermisch et al / The Effects of Vasopressin and Related Peptides on Tolerance to Ethanol, P Hoffman / Sleep Effects of Delta-Sleep Inducing Peptide DSIP, V Susic / Techniques for Investigating the Blood-Brain Barrier in Non Mammalian Species, J. Abbott & B.V Zlokovic / Amino Acid and Prolactin Transport into CNS, A Lorenzo / Amino Acid Uptake in Synaptosomal Preparations, A Lajtha & E A Deibler / Exchange Diffusion of Neutral Amino Acids from Blood to Brain, A Gjedde / Kinetic Analysis of Blood-Brain Barrier Transport with References to Amino Acids, J Hargreaves & V Cunningham / The Mechanism of Amino Acid Transport Across the Chorod Plexus, M B Segal & B V Zlokovic / A Comparative View of Amino Acid Transport at the Blood-Brain and Placental Barriers, D L Yudilevich & C P D Wheeler / Discussion and Conclusions / Index

1988 350pp 234x156mm Hardback £40.00 0-333-45600-9

Peripheral Actions of Dopamine

Edited By Christopher Bell, Department of Physiology, University of Melbourne, Australia and Barry McGrath, Monash University Medical School, Melbourne, Australia

This book reviews the current state of research in three main areas concerning the actions and significance of dopamine in the periphery: the source and effects of endogenous dopamine; the classification and distribution of, and the effects of activating, various populations of peripheral dopamine; and the therapeutic significance of dopamine receptor activation and renal disease.

Contents: Sources of Circulating Dopamine A Personal View, J-L Cuche / Dopamine Storage in Sympathetic Nerves, P Soares-Da Silva / Neurochemistry of Dopaminergic Nerves, C Bell, M Ferguson & T Petrovic / Release of Dopamine from the Kidney in vivo, P Hjemdahl, T Bradley & B. Tidgren / Dopamine and Renal Failure, W Adam / Dopamine and Hypertension, M Yoshimura & H Takahashi / The Vascular (DA1) Dopamine Receptor, J D Kohli & L I Goldberg / Renal Dopamine Receptors, R A Felder, C C Felder, G M Eisner & P A Jose / Gastrointestinal Dopamine Receptors, R A Lefebvre / Neuronal Dopomine Receptors, M F Lokhandwala & M L Defeo / Drug Design for Cardiovascular Therapeutics Activation of DA1 Receptors, B A Berkowitz / Use of Dopamine Agonists in Cardivascular Disease, B P McGrath, N Sano & B F Jover / Mocified Dopamine Agonists, R D Hoskins, R A Brown, R A Foulds, F Ince, S O'Connor & G W Smith / Dopamine Pro Drugs, M R Lee / Index

Pharmacology and Functional Regulation of Dopaminergic Neurons

Edited by Philip M Beart, Geoffrey N Woodruff and David Jackson

This is the proceedings of a Satellite Symposium of the 9th IUPHAR Congress in Sydney in 1987 entitled Dopamine 87 It covers all aspects of research into dopamine systems and their regulation.

Contents All 66 Papers presented at the Satallite Symposium of the 9th IUPHAR Congress

1988 424pp 234x156mm Hardback £45.00 0-333-45944-X

New Concepts in Depression

Pierre Fabre Monograph Series, Volume 2

Edited by M. Briley, Pierre Fabre Medicament, Castres, France and G. Fillion, Head of Neuroimmunoendocrinology, Pasteur Institute, Paris

Depression is increasingly seen as an important debilitating neurological condition. This book brings together a timely collection of results and opinions of the major preclinical and clinical researchers in the field of depression. In addition, a number of chapters concentrate on clinical or physiological phenomena associated with depression. The general attitude of the book is one of openness to new ideas several of which are presented here for the first time.

Contents: The Contributors / Preface to the Series / Preface / Biochemical Mechanisms in Depression / 5-HT and Depression / Physiological Correlates in Depression / From Experimental Models to Man / Clinical Pharmacology of Depression and Associated Phenomena

1988 392pp 234x156mm Hardback £45.00 0-333-44133-8

MRC LABORATORIES
THE GAMBIA, WEST AFRICA

Virologist

Applications are invited for a post of Virologist at the MRC Laboratories, The Gambia You will play a major role in the Unit's research programme on the aetiology of acute respiratory infections in young children and previous experience in this area would be a major advantage You will also be expected to contribute to on-going research studies on polio and measles The virology laboratory at Fajara is well equipped and some technical assistance will be available

This post is on the Council's Higher Scientific Officer scale, £12,259-£15,749 per annum with appropriate overseas cost of living allowance.

Applicants must have at least 2 years' postgraduate research experience with a 1st or 2nd class honours degree

The duration of contract offered is negotiable but will be for a minimum of 2 years.

Application form and further particulars from Tim Quigley (ext 410) The closing date for applications is 11 October, 1989

UNIVERSITY OF DURHAM
Department of Biological Sciences

Lectureship in Animal Cell Biology

Applications are invited for a lectureship in the Department of Biological Sciences to link with the interests of the Animal Cell Biology Research Group Candidates should have interests within the area of animal developmental biology and direct experience of work at the cellular level, preferably in one of the following areas.-

1. Transgenic vertebrates
2. Immunobiology, especially lymphokines
3 Oncogenes and their products
4. Cell signalling systems

It is hoped that the successful candidate would be able to join the Department by 1st April, 1990.

The initial appointment is expected to be on the Lecturer Grade A Scale (£10,458–£15,372), but may exceptionally be on the Lecturer Grade B Scale (£16,014–£20,469).

Further particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE** (Tel 091–374 2265), to whom applications (3 copies, including full CV and the names of three referees) should be sent not later than *Tuesday 31st October, 1989* (Please quote Ref. BS8.) (1668)A

Assistant/Associate Professor
Institute of Molecular Biology and Biochemistry
SIMON FRASER UNIVERSITY

Applications are being accepted for a

DEVELOPMENTAL GENETICIST

Candidates should be applying genetic and/or modern molecular approaches to model developmental systems.

Postdoctoral experience and demonstrated research potential are required Appointment and teaching duties will be in the Department of Biosciences. The Institute was recently established to stimulate expanded graduate training and research and will be occupying a new building in 1992. Set-up funding is available. Applicants should forward a complete curriculum vitae, reprints of most significant recent publications, and three letters of reference to.

Dr. Bruce Brandhorst, Director.
Institute of Molecular Biology and Biochemistry (I.M.B.B.)
Simon Fraser University
Burnaby, B.C. V5A 1S6
Canada

Applications will be evaluated beginning December 1, 1989. Simon Fraser University offers equal employment opportunities to qualified applicants. While all are encouraged to apply, Canadian law requires that consideration in the first instance be given to applicants eligible for employment in Canada at the time of application. (NW4248)A

UNIVERSITY OF WARWICK
Department of Computer Science

RESEARCH ASSOCIATE

Applications are invited for a second Research Associate to join an SERC funded project entitled: "Representation and Inference in a Naive Physics Theory of Space and Time". The project is concerned with building, implementing and applying a logic for representing and reasoning about space and time from a topological and qualitative standpoint. The project is in the spirit of Hayes' Naive Physics programme, and applicants should therefore be interested in building formal theories of the commonsense world in this manner.

Candidates should have a good background in first order logic and be able to program fluently in Lisp, and preferably Prolog as well.

The post will normally be tenable for a maximum of three years in the grade 1B (Salary £9816 – £12381 pa). Registration for a higher degree can be considered from those with suitable qualifications. Postdoctoral candidates and others with higher qualifications are welcome to apply and can expect a higher salary over a shorter period of employment.

Application forms and further particulars from the **Personnel Office, University of Warwick, Coventry CV4 7AL (0203 523627) quoting Ref No 8/3A/89/x/14.** (please mark clearly on envelope).

Closing date for applications 19 October 1989.

Informal enquiries may be addressed to Dr A G Cohn (0203 523088, 0203 523193 or agc@cs.warwick.ac.uk).

AN EQUAL OPPORTUNITIES EMPLOYER (1685)A

BP VENTURE RESEARCH FELLOWS AND ASSISTANTS

Department of Geology (UNIVERSITY OF BRISTOL) Department of Applied Mathematics and Theoretical Physics (UNIVERSITY OF CAMBRIDGE)

Dr. H. E. Huppert (Cambridge) and Professor R. S. J. Sparks (Bristol) are investigating the novel and fundamental effects of particles on fluid flows with applications to sediment transport, volcanism and industrial processes.
The research will involve both theoretical and experimental investigations. The following positions are available.

- ★ Two post-doctoral fellowships (three years)
- ★ Two post-graduate research assistants

Backgrounds such as fluid mechanics, geology, sedimentology, physics and applied mathematics are appropriate. The research will emphasise geological aspects at Bristol and fluid mechanics at Cambridge with close links between the two groups.

Salaries will depend upon relevant experience and status.

Applicants should send a curriculum vitae and the names of two or three referees to either the Personnel Office, Senate House, Tyndall Avenue, Bristol University, Bristol BS8 1TH or directly to Dr. Huppert in the Department of Applied Mathematics and Theoretical Physics, Silver Street, Cambridge CB3 9EW. Further particulars can be obtained from either source.

Bristol University applicants should quote reference number A697 Tel. No. (0272) 303136.
Cambridge University applicants should quote reference number HH1 Tel. No. (0223) 337853 Fax No. (0223) 337918.

ST. MARY'S HOSPITAL MEDICAL SCHOOL
(a constituent College of Imperial College of Science, Technology and Medicine), (University of London), Norfolk Place, LONDON W2 1PG

A post is currently available for a **Research Assistant** in the Department of Dermatology to work on the role of cytokines and psoriasis using a variety of techniques including tissue culture, immunofluorescence and in situ hybridisation. Graduates, preferably with some laboratory experience and a background in immunology, are invited to apply. The position, funded for 3 years, could lead to a PhD degree for a suitable candidate.

For further details 'phone Dr. B. Baker on (01) 725-1083 Applications, accompanied by a full C.V. with names and addresses of 2 referees, should be sent to Personnel Department at above address by 31 October. Please quote Ref: 500. (1664)A

Deep Seismic Reflection Profiling at Cambridge University, England
BIRPS needs a

RESEARCH ASSOCIATE

1 April 1990 to 31st March 1993 for processing, interpretation and modelling of 12,020 km of data reaching into the mantle. Fascinating science in a pastoral setting; academic salary.

Applicants should have a relevant Ph.D. Send CV and names of two referees to **DRUM, BIRPS, Bullard Labs, Madingely Road, Cambridge CB3 0EZ.** (1678)A

Glaxo IMB

GLAXO INSTITUTE FOR MOLECULAR BIOLOGY S.A.

The Geneva biotechnology research unit of the largest U.K. pharmaceutical group has the following positions.

ELECTROPHYSIOLOGIST

The qualified scientist (PhD level) will join an expanding neurobiology research group which is involved in the application of new technology to study the biochemistry and physiology of pharmaceutically important neurotransmitter receptors and their second messenger systems. The scientist will set up and direct an innovative research program and have responsibility for several technicians.

The ideal candidate will have 3 to 5 years of relevant experience in the following areas. voltage clamp analysis on single cells (or oocytes), patch clamp analysis and neuronal cell culture techniques.

PROTEIN CHEMIST

Head of the Department of Analytical and Recombinant Protein Chemistry

The qualified scientist (PhD level) will lead a group of 8 to 10 scientists and technicians involved in the purification and characterization of recombinant proteins, synthesis and purification of peptides and microsequence analysis of proteins.

The ideal candidate will have at least 5 years of relevant academic or industrial postdoctoral experience in the area of micro-analytical protein chemistry.

We offer an excellent salary and benefits package, with opportunities for career development in one of the most attractive parts of Europe.

If you are interested in either of these positions, please send your curriculum vitae with a list of publications and the names of three references to: Rita Gloor, Personnel Manager, GLAXO IMB S.A, 46, route des Acacias, 1211 Geneva 24, Switzerland.

ROYAL HOLLOWAY AND BEDFORD NEW COLLEGE
University of London

SCHOOL OF LIFE SCIENCES
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited for the position of Postdoctoral Research Assistant to work with Drs C Rider and A D Stead on the role of the ubiquitin in plant senescence Ubiquitin is a small protein involved in the targetting of proteins for rapid degradation This project is funded for 3 years by the AFRC as part of the recent Plant Molecular Biology Programme. Applicants should possess or be expecting shortly to gain a PhD in Biochemistry, Plant Physiology or related discipline.
The experimental programme will involve Western blotting using specific antisera and the application of oligonucleotide probes. This new project will be conducted alongside both existing work on ubiquitinated proteins from other sources, and other plant molecular biology projects. Salary on the scale £12,108 – £18,315 per annum, including London allowance
Informal enquiries may be made to the supervisors (0784 434455 ext 3548 or 0784 435551 ext 38) Applications, including a full c v and the names and addresses of two referees, should be submitted to the **Personnel Officer, Royal Holloway and Bedford New College, Egham Hill, Egham, Surrey, TW20 0EX as soon as possible.** (1676)A

IMMUNOLOGISTS

The University of Washington seeks highly-qualified applicants for tenure-track appointments in the newly formed Department of Immunology. Applicants must have demonstrated their ability to establish strong independent research programs in immunobiology. The Department of Immunology offers superb new laboratory space with access to flow cytometry, biopolymer synthesis, and transgenic animal facilities. Send curriculum vitae, a brief description of proposed research, and three letters of recommendation (by December 1, 1989) to **R.M. Perlmutter, M.D. Ph.D., Chairman, Department of Immunology, SL-05, University of Washington, Seattle, WA 98195.**

The University of Washington is an Equal Employment/ Affirmative Action Employer. (NW4287)A

AFRC INSTITUTE FOR ANIMAL HEALTH PIRBRIGHT LABORATORY

MOLECULAR BIOLOGIST/VIROLOGIST (SENIOR SCIENTIFIC OFFICER)
IMMUNOLOGIST (HIGHER SCIENTIFIC OFFICER)

to work on

MOLECULAR BIOLOGY AND IMMUNOLOGY OF RINDERPEST VIRUS— RESEARCH PROJECT FUNDED BY THE WELLCOME TRUST

Rinderpest virus is a serious veterinary pathogen, closely related to measles and canine distemper virus, which affects ruminants in many developing countries. It is an excellent model for the study of virus pathogenicity in the natural host at the molecular level since strains differing greatly in their virulence have been isolated For the senior position (SSO), we are looking for a scientist who is interested in the analysis of the structure and function of virus proteins using molecular biological techniques. For the junior position (HSO), we are looking for a post-doctoral scientist interested in the immunology of virus infections SSO position for approximately 5 years and the HSO position for 3 years.

Qualifications.
First or second class honours degree in appropriate subject Ph.D. preferred for both posts

Experience:
For SSO appointment a minimum of four years' post-graduate research experience is essential. For HSO, candidates must offer at least two years' post-graduate experience directly relevant to the post

Salary:
SSO £12,445-£17,032
HSO £10,026-£13,460
PAY AWARD PENDING

Annual Leave:
25 days plus 10½ days public and privilege holiday
Applications already received will be considered.

Informal enquiries can be made by phone **(0483 232441)** to **Dr T. Barrett** or letter to **Dr C.J. Bostock, Head of Molecular Biology.** Applications including a full curriculum vitae and the names of two referees should be sent to:

Laboratory Administrator, AFRC Institute for Animal Health, Pirbright Laboratory, Pirbright, Woking, Surrey GU24 0NF.

Closing date 19th October 1989.

AFRC is an equal opportunity employer (1710)A

THE INSTITUTE FOR ADVANCED STUDY

Will have an opening for a long-term (5 year) member in high energy physics and field theory beginning September 1990. Salary is above post-doctoral level and is commensurate with qualifications. In addition to exceptional qualifications for pursuing his or her individual research, the successful candidate should be interested in talking to, and possibly collaborating with, other post-doctoral members. The duties of a long-term member consist only of performance of individual research, being helpful to other members in their research, helping run seminars and reviewing post-doctoral applications. Requests for application should be addressed to **Michelle Sage, School Administrative Officer, School of Natural Sciences, Institute for Advanced Study, Princeton, NJ 08540.** The closing date for applications is December 15, 1989. The Institute for Advanced Study is an affirmative action/equal opportunity employer. (NW4209)A

UNIVERSITY OF CAMBRIDGE
Department of Clinical Biochemistry

POST-DOCTORAL RESEARCH ASSOCIATE

Applications are invited for a position funded by the British Diabetic Association, to work on the structure and regulation of receptors for glucagon and insulin. The project will particularly involve the preparation and use of anti-receptor antibodies. The post is available for 2½ years, to commence as soon as possible, with salary in the range £10457-£13526 p.a. according to age.

Applications, including names of two referees, to **Dr. K. Siddle, Department of Clinical Biochemistry, Addenbrookes Hospital, Hills Road, Cambridge, CB2 2QR,** (by October 18th), or telephone 0223 336780 for further information. (1687)A

National Institute of Genetics
DNA Data Bank of Japan

Associate Professor

One post is available for a researcher whose training is in biology, biophysics, computer science, mathematics or another natural science, and who is interested in building and maintaining a DNA database, as well as sequence and structural analysis of DNA and proteins in approaches of biophysics, molecular evolution and computer science. The successful applicant is expected to be a good collaborator with Dr. Sanzo Miyazawa, who is the manager of the DNA Data Bank of Japan and other staffs.

Qualification: M.Sc. or Ph.D. is desirable. Basic knowledge of computer science and experience of using UNIX systems are required.

Duration: An appointment is for an initial three-year period as a governmental employee and may be extended.

Appointment: After Jan. 1, 1990.

Location: National Institute of Genetics, Mishima, Shizuoka 411, Japan.

The National Institute of Genetics is a governmental organization in Japan. The DNA Data Bank of Japan is collecting DNA data and building and maintaining a DNA database in collaboration with GenBank and the EMBL Data Library. The available computer system consists of Sun workstations, an Iris Graphic workstation, a FACOM M380Q/UTS(Unix), and a Micro VAX-II/VMS.

Applications, together with a curriculum vitae, a publication list, copies of some publications, a research history, research interests, the names and addresses of two persons for recommendation, should be sent to **National Institute of Genetics, Mishima, Shizuoka 411, Japan**, before December 31, 1989.

For details, please contact with Dr. Sanzo Miyazawa. His electronic mail address is smiyazaw%ddbj.nig.ac.jp@relay.cs.net, fax number is +81 559 75 6040: phone number is +81 559 75 0771 ext. 649. (W6529)A

UNIVERSITY OF GLASGOW
Department of Dermatology

BIOCHEMIST/MOLECULAR BIOLOGIST CELL BIOLOGIST

Two vacancies are available for postdoctoral and postgraduate research assistants to study expression and properties of steroid hormone receptors and enzymes of steroid synthesis in cells cultured from human hair follicles. Work will be based in well equipped laboratories in the dermatology department which also houses several other active research groups. This project is part of a joint, industrially funded research programme between the Universities of Dundee & Glasgow on the regulation of mammalian hair growth. Starting salaries in the range £9,816-£13,527 per annum on Research 1A or 1B scales depending upon qualifications and experience. Appointments may be renewed for up to 3 years. Applications including a full C.V. and names of two referees should be sent to **Dr. M.B. Hodgins, Dermatology Department, Glasgow University, Anderson College Building, 56 Dumbarton Road, Glasgow, G11 6NU.** (1686)A

University College London
Southern African Wood Studies (SAWS)

A multi-national interdisciplinary research group is seeking a research technician, Grade D, with experience of stable isotape analysis. The aims of the project are to characterize the stress responses of African Fuel Wood trees and the technician will be responsible for operating a new Europa Roboprep-Tracermass system.

— Opportunity for fieldwork in Zimbabwe.

Salary in range £8,645–£8,904 + London Weighting of £1,750.

Applications to **Professor G.R. Stewart, Department of Biology (Darwin Building), University College London, Gower Street, London WC1E 6BT.** Telephone: 01-387 7050 ext. 2653. Equal Opportunities Employer.

RENEWAL OF PROCLAMATION FOR THE POST OF DIRECTOR OF THE NATIONAL CENTRE FOR MARINE RESEARCH

GENERAL SECRETARIAT FOR RESEARCH AND TECHNOLOGY

MINISTRY OF INDUSTRY, ENERGY AND TECHNOLOGY

The N C.M R is seeking candidates for the post of Director of the National Centre for Marine Research after the resignation of the only one candidate proposed by the National Advisory Research Council to the Minister for Industry, Energy and Technology

1. Candidates for this post would possess the following qualifications, according to the article 9, par 6 of the Greek Law 1514/85:

a) To have Greek citizenship

b) Recognised scientific research activities related to at least one of the research fields of N.C.M.R. Institutes (Oceanography, Marine Biological Resources, Inland Waters)

c) Proven ability to develop research in new fields, to coordinate and progress multidisciplinary research programmes, to contribute to the determination of research policy and to have international recognition for contribution to the respected scientific field, as evidenced by multiple publications and monographs in peer-reviewed literature with international reputation

d) To be not older than 62 years of age on the date of their engagement

2. The appointment of the Director of N.C.M.R. by the Minister for Industry, Energy and Technology is for a 3-years period, according to the procedure indicated by article 9, par 5, Greek Law 1514/85.

3 The Director of N.C.M.R. will be fully engaged with the duties risen by the Centre However, part-time research could be performed only in the same research Centre (N.C M R)

4. Other provisions are applicable, related to article 9, 10 and par. 18, Greek Law 1771/88

5 Applications and a full curriculum vitae (in 5 copies) should be sent to: **General Secretariat for Research and Technology, Dept for Research Institutes, 14-18 Messogion Avenue, Athens. GR 115 10, Greece,** not later than 30 November 1989

The Minister of Industry, Energy and Technology

M Papaconstantinou

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)

Research Technician/Trainee Technician

Department of Histochemistry

A science graduate or person with some training in pure or applied biological sciences is needed to join a team investigating neurotransmitters in the nervous system. The successful applicant will gain experience in a wide variety of techniques including tissue sectioning, immunostaining and microscopy

The post is available on a full or part time basis and could suit a School Leaver with at least 2 Science A levels, a graduate, a trained technician or a mature person wishing to return to work. Opportunity available for higher degree for suitable candidates.

Salary depending on age and qualifications ranging from (Research Technician) £8,682–£11,415 or (Trainee Technician) £5,898–£8,397.

Application forms and further particulars are available from the **Personnel Office, Royal Postgraduate Medical School, Du Cane Road, London W12 0NN** (Tel: 01–740 3204) quoting ref: AHY7. *Closing Date: 13 October 1989* (1662)A

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

CHAIR OF IMMUNOLOGY

The University of Nottingham invites applications for the Chair of Immunology based in the Medical School at University Hospital. Immunology is fully integrated in regard to academic and health service roles and its development at Nottingham is central to the expansion of research in the area of Molecular Medicine Applications from medically qualified immunologists and basic scientists will be given equal consideration The successful applicant will be capable of participating in a first class laboratory service and relevant research, and will be expected to give academic leadership in teaching and research activities. For academic purposes the department is part of the University Department of Microbiology under the leadership of Professor J P Arbuthnott

The salary will be within the appropriate professorial range with membership of USS and, for medically qualified applicants, an honorary consultant appointment with the Nottingham Health Authority will be associated with the Chair.

Full particulars of the appointment, together with relevant documents concerning the Medical School, and application forms, may be obtained from the **Deputy Registrar and Secretary, Medical School, Queen's Medical Centre, Nottingham NG7 2UH (telephone 0602–709381)** to whom applications should be returned by 30th OCTOBER 1989.

The subject is funded by Overseas Development Natural Resources Institute and is expected to contribute towards policy making in banana disease control, with particular reference to black leaf streak Starting salary up to £12,381 p.a. Apply for Application Form and further particulars to the **Personnel Officer, University of Reading, Whiteknights, P.O. Box 217, Reading RG6 2AH, telephone (0734) 318754** Closing date 30 October 1989 Please quote Ref R8963. (1672)A

SHAPING YOUR FUTURE

PSC-CFP

The People

The people who work for Energy, Mines and Resources in Ottawa share the possibility of a career with few boundaries. In fact, by working for one of the 70 departments and agencies that make up the Federal Public Service, they gain experience that enhances their professional development and opens national and international doors. To ensure that all candidates have every chance on an equal basis, we encourage equitable participation by women, aboriginal peoples, members of visible minority groups and persons with disabilities.

Your Choice

Research Scientist
($32,948 - $61,284)

Conduct original research into fundamental problems of crustal and lithospheric evolution and be involved in areas of solid-earth geophysics and impact processes as they relate to the study of evolution. Participate in the development of research programs.

Your Contribution

A doctoral degree from a recognized university in the field of earth sciences or a lesser degree with evidence of research experience and productivity equivalent to that of a doctoral degree. Research experience in the field of tectonophysics, potential field studies, remote sensing or mathematical modelling. Experience in writing and presenting research results to the scientific community and high productivity in addressing scientific problems.

Knowledge of English or French is essential.

Send your application by November 15, , 1989, quoting reference number: S-89-31-5873-47JG-G26, to: Joan Girling (613) 996-8054, Public Service Commission of Canada, 171 Slater Street, Ottawa, Ontario, Canada K1A 0M7.

Personal information you provide is protected by the Privacy Act. It will be held in Personal Information Bank PSC/P-PU-040.

INSTITUTE OF TERRESTRIAL ECOLOGY
MERLEWOOD, CUMBRIA
MICOLOGIST/POPULATION BIOLOGIST

Merlewood Research Station are seeking to appoint a Postdoctoral Research Fellow under the Joint Agriculture and Environment Programme for a period of three years. The postholder will study the theory of patch dynamics and island biogeography as it relates to straw decomposition Specifically the work will be related to the interaction between straw and plant roots as resources for decomposer fungi and mycorrhizas.

The successful candidate will work closely with a joint post at Lancaster University whose main remit will be to investigate the role of earthworms and collembolla as vectors for fungal propagules between straw resource units.

Applicants will have obtained or are due to obtain a PhD in an appropriate discipline and should have experience in plant ecophysiology. Experience in computer programming would be an advantage.

Salary in the range of £10,678 to £14,909 per annum dependent upon qualifications and experience, and benefits include generous leave allowance and non contributory pension scheme.

The Institute of Terrestrial Ecology is a component body of Natural Environment Research Council.

Application forms are available from

Mr D Simms, Station Secretary,
Institute of Terrestrial Ecology,
Merlewood Research Station,
Grange-over-Sands-Cumbria, LA11 6JU.
Telephone 05395 32264.

Closing date for completed applications: 19th October 1989.

The Natural Environment Research Council is an equal opportunities employer. (1699)A

Natural Environment Research Council

Post Doctoral Research Associates

5 positions available this Fall for a multidisciplinary approach to study peptides and proteins for biological and clinical applications Candidates should have experience in one of the following areas. 1) Peptide Synthesis 2) Immunology 3) Cell Biology 4) HIV 5) Blood Coagulation 6) Growth Factors

ROYAL FREE HOSPITAL SCHOOL OF MEDICINE
(University of London)
POSTDOCTORAL RESEARCH ASSISTANT
DEPARTMENT OF ANATOMY

Applications are invited for the post of postdoctoral Neuroscientist to work on a 3 year project funded by the Wellcome Trust studying mechanisms regulating ageing in the nervous system. The project will investigate neurone-target interactions using immunohistochemistry, neuronal tracing techniques and tissue transplantation in a small, expanding research group. Knowledge of one or more of these techniques is an advantage, but not essential. Starting salary on Range 1A up to £12,381 plus £1,650 London Allowance

Job description available from the **School Office, Room G668, R F.H S.M., Rowland Hill Street, London NW3 2PF, tel: 01-794 0500, extn. 4262,** to which TWO COPIES of curriculum vitae (with names and addresses of two referees) should be sent by 12 October 1989. Please quote ref· A/R/15(a) (1674)A

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
DEPARTMENT OF CELLULAR & MOLECULAR SCIENCES
POSTDOCTORAL RESEARCH FELLOW

Required for a two year position funded by the Wellcome Trust to join an existing team investigating the control of growth and differentiated function in human thyroid cell lines. Applicants should have a background in the biosciences, preferably with biochemical or endocrinological experience. The position is available now and salary is on the 1A scale

Enquiries to either Dr S Nussey (01.672-9944 ext 55803) or Dr A Johnstone (ext 55780) Applications, comprising c.v. and the names of two referees, to either person: **St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE.**

Closing date: 26th October 1989 **(1713)A**

ASSISTANT OR ASSOCIATE PROFESSOR
EVOLUTIONARY/POPULATION GENETICS

Tenure track position open September 1990 for an evolutionary or population geneticists. Post-doctoral experience desirable Expected to develop a productive research program and interact with strong marine ecology and molecular genetics groups in the department Application of molecular methodology to field populations is of particular interest. Generous start-up funding and other allowances negotiable. Graduate and undergraduate teaching responsibilities.

Send resumé and publications. Three or more reference letters from professional associates requested

Application deadline 1 December 1989.

Dr. Sarah Woodin, Chair, Population Genetics Search Committee, Department of Biological Sciences, University of South Carolina, Columbia, SC 29208, (803) 777-5084.

An Equal Opportunity/Affirmative Action Employer. (NW4294)A

THE UNIVERSITY OF BIRMINGHAM
SCHOOL OF BIOLOGICAL SCIENCES
RESEARCH FELLOW

A Research Assistant is required to work on a programme involving the genetical analysis of early maturity and other economic traits of sunflowers, particularly the production of second cycle inbreds/hybrids from selected sunflower crosses and their assessment under field conditions Candidates are expected to have experience in biometrical genetics, statistical analysis, computing and large scale field experiments with plants A PhD qualification is desirable but not essential

Maximum starting salary £11,088. The post is tenable for three years from 1 October 1989 or as soon as possible thereafter. For further particulars and an application form please telephone 021-414 6483 (24 hour answerphone) quoting reference 2175 Applications should be sent to **The Director of Staffing Services, The University of Birmingham, Edgbaston, Birmingham, B15 2TT** by 13 October.

AN EQUAL OPPORTUNITIES EMPLOYER (1719)A

UNIVERSITY OF
essex

Department of Biology

Research Officer for Antarctic Microbiology

Suitably experienced microbiologists are invited to apply for a Research Officer post to carry out research on microbial activity in Antarctic coastal marine sediments The project, in collaboration with the British Antarctic Survey, will include a continuous period of approximately 21 months absence from the U.K for field work at the Signy Island base, applicants, to work mainly overseas, must be single, male and physically fit. The post is for 3 years and will commence early in the new year Appointment to the postdoctoral Senior Research Officer grade (Grade IA £10,458-£16,665) is preferred, but well qualified postgraduates will be considered for appointment as Research Officer (Grade IB £9,816-£12,381).

Informal enquiries may be made to Dr D B Nedwell (0206 872211).

Applications (three copies), including a curriculum vitae and the names and addresses of two academic referees, should reach the Registrar (R/968/N), University of Essex, Wivenhoe Park, Colchester, CO4 3SQ by 20th October 1989. Further particulars of this post may be obtained by telephoning Colchester (0206) 872462 (24 hours).

(1688)A

Faculty Position, Microbiology UCLA

The Department of Microbiology, College of Letters and Science, University of California, Los Angeles has a tenure-track position available for a molecular biologist. The primary areas of recruitment interest are, 1) molecular genetics of yeast, 2) molecular aspects of archaebacteria. A Ph.D. or equivalent as well as several years of post-doctoral experience in microbiology, molecular biology, or a related field is required, with evidence of research accomplishments and teaching abilities. The individual selected will be expected to establish a strong research program as well as participate in undergraduate and graduate student teaching. Title and salary (nationally competitive) are commensurate with qualifications and experience with preference for an entry level position. Applicants should send a letter of application, curriculum vitae, summary of research interest, relevant publications, and the names and addresses of three references to **Dr. Virginia L. Miller, Dept. of Microbiology, UCLA, 405 Hilgard Ave., Los Angeles, CA, 90024.** Deadline for applications is December 15th, 1989. UCLA is an equal opportunity employer —women and minorities are encouraged to apply.

(NW4288)A

UNIVERSITY OF LEICESTER
POSTDOCTORAL RESEARCH ASSOCIATES

Two postdoctoral Research Associate positions are available for: (1) an immunologist and (2) a molecular biologist. The successful applicants will join a research team investigating the genetic design and evaluation of novel vaccines against parasitic and bacterial diseases.

1. **Immunologist:** The applicant should have a strong background in immunology and an interest in either basic vaccinology, mucosal immunity, or host restriction. The position offers the scope for active collaboration with researchers in Switzerland, Sweden and Italy, and opportunities to work in these participating laboratories will be encouraged
2. **Molecular Biologist:** The applicant should have a strong background in molecular genetics and an interest in the application of protein engineering techniques. The position will ential active collaboration with a major pharmaceutical company

The appointments will have a starting salary of up to £14,169 (position 1) and £12,381 (position 2) per annum, depending on qualifications and experience (RA IA scale £10,458-£16,665 per annum). Further details may be obtained from Dr. T. R. Hirst (0533-523431).

Applications, including a full c v and the names and addresses of three referees, should be sent to **Dr. T. R. Hirst, Department of Genetics, University of Leicester, Leicester LE1 7RH** by 7 October 1989. (1675)A

JAMES BLACK FOUNDATION

ORGANIC CHEMISTS AND PHARMACOLOGISTS

The James Black Foundation is a new biomedical research company. The team of medicinal chemists and pharmacologists work closely together utilising the first-class facilities at our Dulwich laboratories in South London. Our approach involves modelling led drug design integrated with advanced methods of bioassay.

Expansion of the chemistry group has identified the following vacancies for organic chemists.

1. A postdoctoral medicinal chemist.

You will have up to five years postdoctoral experience gained mainly in the pharmaceutical industry and will be capable of initiating and running your own programmes of work within the highly interactive context of the Foundation. You will have the versatility to deal effectively with the variety of demands that arise in our tight-knit group. Please quote reference NAT1089-1.

2. A graduate synthetic chemist.

You will have up to five years experience gained within the fine chemical or pharmaceutical industry, and have a strong interest in practical synthetic organic chemistry. You must be capable of working towards designated synthetic targets with the minimum of direct supervision. Please quote reference NAT1089-2.

3. A computer literate organic chemist.

You will have two to five years postdoctoral experience; your PhD and subsequent work should reflect your interest in the properties of molecules and in modern analytical and computational techniques. The Foundation currently possesses an Evans and Sutherland graphics system linked to a VAX, a 300 MHz NMR, FT-IR, preparative and analytical HPLC and a number of other devices. Please quote reference NAT1089-3.

4. A graduate pharmacologist.

You will be required to perform and design in-vitro pharmacological experiments, participate in the daily running of the laboratory and contribute to meetings of the research programme groups. Whilst not an essential requirement, previous experience in the pharmaceutical industry will be considered an important advantage. Please quote reference NAT1089-4.

The **James Black Foundation** is a non-profit making company, limited by guarantee, and is funded by one of the world's major pharmaceutical and healthcare companies. Salary structure, benefits and pension scheme are competitive with the pharmaceutical R. & D. sector.

Interested candidates should submit their curriculum vitae together with the names of two referees to Mrs. L. Michie, James Black Foundation, 68 Half Moon Lane, London SE24 9JE, by the closing date of October 27th 1989. (1694)A

UNIVERSITY OF WARWICK
DEPARTMENT OF BIOLOGICAL SCIENCES

RESEARCH POSTS IN ERWINIA GENETICS AND MOLECULAR BIOLOGY

(Molecular plant pathology, Enzyme secretion and Antibiotic biosynthesis)

Applications are invited for five research posts to work on various aspects of *Erwinia* genetics and molecular biology The successful applicants will join a large, active group currently investigating molecular mechanisms involved in *Erwinia* pathogenicity of potato; extracellular enzyme (pectinases and cellulases) secretion mechanisms (transmembrane protein targeting), and carbapenem antibiotic biosynthesis. The projects are supported by SERC and AFRC grants to Dr G P.C. Salmond

At the postdoctoral level, applicants with skills in bacterial genetics/molecular biology, recombinant DNA methods, enzymology or antibiotic biosynthesis studies would be at an advantage, but applications will also be very welcome from other appropriately qualified candidates in general biological sciences, for whom training can be given.

Postdoctoral positions (3)
Two positions are for work on the molecular biology of enzyme secretion/protein targeting and phytopathogenicity. One position is for a collaborative project investigating the molecular genetics and biochemistry of carbapenem antibiotic biosynthesis One post is for approximately twenty-five months and the other two are for three years. Applicants should have, or expect to have shortly, a PhD in molecular biology, microbiology, biochemistry, genetics or a related biological science

Technician (1)
One technical post is available for three years on the antibiotic project. Candidates should have a degree in a biological science and an interest in molecular genetics/biochemistry or antibiotics

Postgraduate Research Studentship (1)
One AFRC-funded PhD studentship is available to work on the molecular basis of extracellular enzyme secretion in *Erwinia,* as part of a large research group working in this area. Applicants should have at least a 2(1) Honours degree in a biological science and an interest in using genetics, biochemistry and genetic engineering techniques to analyze protein targeting mechanisms in bacteria. The closing date for the studentship nomination is the 30th November 1989

All posts are available from October 1st However, with the exception of the studentship, appointments can be made anytime between October 1, 1989 and March 31, 1990 The postdoctoral positions are on salary scale RAIA: £10,458 to £16,665 p.a , and the technician on TG3. £7,479 to £8,645.

Applicants should apply to the **Executive Officer (Noreen Rowe), Department of Biological Sciences, University of Warwick, Coventry, CV4 7AL, England** (telephone· 0203–523517) by sending a full c.v., including the names and addresses of two referees, quoting Ref. No. GPCS/BS337/14. (1692)A

LEICESTER POLYTECHNIC

DEPARTMENT OF APPLIED BIOLOGY AND BIOTECHNOLOGY

LECTURER/SENIOR LECTURERS (Two Posts)

Salary up to £18,549 p.a.

Post 1: Biochemical Physiology

Post 2: Agricultural Biology

The successful applicants will play a full part in research and teaching (Higher Degrees, BSc (Honours) and HND programmes) in this thriving Department.

The posts are tenable as soon as possible.

Application forms and further details available from The Personnel Department, PO Box 143, Leicester LE1 9BH. Telephone Leicester (0533) 551551 ext. 2593. Closing date 12th October 1989.

An Equal Opportunity Employer (1712)A

HUNTERIAN INSTITUTE, ROYAL COLLEGE OF SURGEONS INSTITUTE OF NEUROLOGY, NATIONAL HOSPITAL LONDON

POST-DOCTORAL SCIENTISTS AND TECHNICIAN

To work on a research programme on the use of ^{1}H NMR spectroscopy for the investigation of brain metabolism. This 5 year programme, funded by the Wellcome Trust, consists of several interlinked projects that will be carried out on a variety of preparations, including clinical biopsy material, cell cultures, brain slices, and disease models. This work will be closely integrated with whole body studies.

TECHNICIAN: to work with Mr D G T Thomas and Dr J Darling, on the preparation and analysis of glioma cells Previous experience of cell culture or biochemistry would be an advantage, but no previous experience of NMR will be required Based at the Institute of Neurology.

POST-DOCTORAL SCIENTIST (PHYSIOLOGIST OR SPECTROSCOPIST): whose work would include the interfacing of several techniques, including NMR spectroscopy, near infrared spectroscopy, and hydrogen clearance. This would involve collaboration with groups at University College London.

POST-DOCTORAL NEUROCHEMIST: to contribute to the integration of the cellular, brain slice, and *in vivo* studies.
Post-doctoral posts, based at the Royal College of Surgeons.

Informal enquiries and applications (full CV and names and addresses of two referees), to:

Professor D.G. Gadian
Hunterian Institute
Royal College of Surgeons of England
35-43 Lincoln's Inn Fields
London WC2A 3PN
Tel: 01-405 3474

Closing date: 19 October

UNIVERSITY OF BRISTOL

TWO POST-DOCTORAL RESEARCH ASSOCIATES IN THE BRITISH HEART FOUNDATION RESEARCH GROUP IN CELLULAR CARDIOLOGY

Applications are invited for two 1A Research Associates to join Professor R A Chapman in the newly formed British Heart Foundation Research Group in Cellular Cardiology which is part of the Department of Physiology The positions will be funded for 5 years and can start from 1st January 1990. The Group will concentrate upon research into the processes involved in cardiac muscle cell death. Experience with isolated cardiac myocytes, voltage clamp, single channel recording, ion-sensitive and oxygen electrodes would be an advantage. Candidates with qualifications more suitable for a 1B Research Assistantship are not discouraged from making an application

Informal contact or visits to the laboratories can be arranged by telephoning Prof. R A Chapman on (0270) 260360 or 303199.

For further details telephone Bristol 303136 (ansaphone after 5.00 p.m.) or write to the **Personnel Office, Senate House, Bristol BS8 1TH. Please quote reference A746.**

The current salary ranges are 1A £10458 – £16665 and 1B £9816 – £12381. (1689)A

The Division of Medical Genetics
Emory University School of Medicine

ASSISTANT LABORATORY DIRECTOR

The Division of Medical Genetics, Emory University School of Medicine, is seeking application for an assistant laboratory director of the cytogenetics and prenatal diagnosis laboratory To apply, send curriculum vitae and a synopsis of current and future research interest to:

Dr. Louis J. Elsas, II, Director,
Division of Medical Genetics,
Emory University School of Medicine,
2040 Ridgewood Drive,
Atlanta, GA 30322.

Deadline for receipt of application is October 31, 1989.

Emory University School of Medicine is an Equal Opportunity/Affirmative Action Employer. (NW4264)A

University of Southampton

POST-DOCTORAL FELLOW IN PEPTIDE CHEMISTRY

THE INSTITUTE OF BIOMOLECULAR SCIENCE

Applications are invited for a post-doctoral position to work on the synthesis of peptides directed to the epidermal growth factor receptor. The project is supported by the Cancer Research Council and is being conducted under the umbrella of the Institute of Biomolecular Science involving close collaboration between the departments of Biochemistry, Chemistry and Oncology. The appointment is for a 3 year period and the successful candidate will work with Professor M Akhtar in the Biochemistry Department during the first phase of the work and then with Dr Nigel Richards in the Department of Chemistry. The appointment will be on a Research Assistant 1A scale (£10,458-£12,381) depending on age.

Applications (1 copy) should be addressed to **Professor M Akhtar FRS, Director — Institute of Biomolecular Science, (Biochemistry Division), University of Southampton, Bassett Crescent East, Southampton, SO9 3TU.** Please quote reference number 59/JAD/jm. (1636)A

Ph.D. POST DOCTORAL POSITION in the DIVISION OF ENDOCRINOLOGY

Department of Pediatrics, Children's Hospital of Pittsburgh

Project involves isolation, purification and cloning of peptide hormone receptor(s). Experience/extensive training in molecular biology and biochemistry essential. Position offers opportunity for career advancement and subsequent independent research in related field of developmental endocrinology and physiology. Apply with c.v. and four references to **Mark A. Sperling, M.D., Chairman, Department of Pediatrics, Children's Hospital of Pittsburgh, 3705 Fifth Avenue, Pittsburgh, PA 15213.** *AN EQUAL OPPORTUNITY EMPLOYER*

(NW4282)A

University of Namibia

Faculty of Science

The University of Namibia is in Windhoek, a vibrant city and the nerve-centre of SWA/Namibia. From this metropolis, one has easy access to some of the world's most interesting wildlife areas, not to mention the unspoilt beaches and vast desert areas.

Senior Lecturer: Chemistry

A PhD and broad-ranging interest in chemistry are required for this appointment — which may be made at Acting Head level.

Senior Lecturer: Statistics

This opening, which could well be an Acting Head of Department position, would suit someone with a PhD and a wide interest in statistics.

Lecturer: Statistics

Master's degree, with statistics as a major, would qualify you for selection.

The above appointments will involve such functions as administration, teaching, research and curriculum development.

Date of commencement of duties: 1 February 1990 or earlier.

Closing date: 23 October 1989.

International Dialing Code to SWA/Namibia: 01026461

Contact Persons: Miss S Damon at 307-2146 or Miss A van Rhyn at 307-2002.

The reward package in each case is most attractive and would include assistance with relocation expenses.

Applications (or preliminary telegraphic applications) must include a detailed c.v. and be submitted to: The Personnel Department, University of Namibia, Private Bag 13301, Windhoek 9000. SWA/Namibia (or telex 0908-727 or fax (01026461) 307-2444).

University of Namibia

(W6515)A

MRC Trauma Group — North Western Injury Research Centre
University of Manchester

Post-doctoral Scientist

Applications are invited for the above three year appointment to work on aspects of the control of energy metabolism after injury. The project forms part of an integrated programme of clinical and experimental studies of the physiological, metabolic and endocrine changes after injury and sepsis.

The successful candidate will have several years' relevant post-doctoral experience and be able to work with critically-ill patients.

The salary will be on the MRC non-clinical scientific grade II scale (£10,456-15,372) according to qualifications and experience.

Further details may be obtained from **Dr. R.A. Little, NWIRC, University of Manchester Medical School, Stopford Building, Oxford Road, Manchester M13 9PT (tel: 061 275 5183/4).**

Closing date for applications 16th November 1989. (1723)A

Laboratoire de Genetique Moleculaire des Eucaryotes

Cellular Immunology

POSTDOCTORAL POSITION

Applications are invited for a postdoctoral position available for 2-3 years. The successful applicant will join a new group whose research interests include mouse T cell development and differentiation. Experience in molecular biology or cellular immunology is preferred. This group is part of an Institute of molecular biology whose strength is in the study of eukaryotic gene expression and close collaboration with the molecular immunology group of Drs. D. Mathis and C. Benoist is envisaged. Knowledge of French is not required. Please submit a full cv and letters of recommendation to: **Dr. Rod Ceredig-Laboratoire de Genetique Moleculaire des Eukaryotes-11, rue Humann-67085 Strasbourg Cedex, FRANCE. Tel. (33) 88 37 12 55. Fax. (33) 88 37 01 48.**

(W6520)A

La Trobe University Australia

School of Biological Sciences

RESEARCH FELLOW

(Fixed term for 3 years, commencing 1 December, 1989.)

This position is supported by a joint grant from the Horticultural Research & Development Corporation and the Australian Mushroom Growers' Association to Dr B. Macauley and Professor B.A. Stone for research into the macronutrient composition of cereal straw compost as a substrate for mushroom growth through composting to fruiting body production. Applicants should have experience with modern methods of cell wall chemistry, including mass spectrometric and NMR spectroscopic techniques for the characterisation of polysaccharides and lignins. A knowledge of basic microbiology would be an advantage. Preference will be given to postdoctoral applicants but non-doctoral applicants with suitable backgrounds will be considered. Salary will be commensurate with qualifications.

Enquiries may be directed to the Department of Biochemistry (tel. (61 3) 479 2196).

Closing Date: 3 November 1989 Ref. No. ACA 0/1232

Salary: $A31,259-$A33,936 - Research Fellow
$A27,139-$A30,882 - Senior Research Assistant

Applications (marked confidential) including reference number, names and addresses of three referees and curriculum vitae should be forwarded to the Staff Officer, La Trobe University, Bundoora, Victoria, Australia, 3083.

Equal Opportunity is University Policy.

(W6524)A arm21350

GLASGOW: EUROPEAN CITY OF CULTURE 1990
UNIVERSITY OF GLASGOW

Departments of Genetics and Medical Genetics
Post-Doctoral Research Assistant

A 3 year post-doctoral position is available to evaluate and apply a novel "subtraction" method for cloning human genes of medical significance. The project is funded by the MRC as part of the Human Genome Mapping Programme. Candidates must have previous experience in molecular biological techniques but experience with human systems is not essential.

Informal enquiries or formal applications including full CV and names and addresses of two referees may be made to **Dr. K. Kaiser, Department of Genetics, University of Glasgow, Church Street, Glasgow G11 5JS;** Tel 041–339 8855 ext. 5112, or to **Professor J.M. Connor, Department of Medical Genetics, Yorkhill, Glasgow G3 8SJ;** Tel: 041–339 6996. (1665)A

UNIVERSITY OF ABERDEEN
POSTDOCTORAL OPPORTUNITY IN PROTEIN ENGINEERING
A Postdoctoral Fellow

is required for site-directed mutagenesis work on complement anaphylatoxins. This is an opportunity to join a project on the structure and function of a small protein using molecular modelling to design mutants that can be tested for biological activity and for solution conformation Further details from Professor John Fothergill, Department of Biochemistry, University of Aberdeen. (J. Fothergill @UK.AC.ABDN) or Tel 0224 273101. Salary within range £10,458-£11,736 per annum (Enjoy living in one of Britain's most agreeable environments!)

Further particulars from the Personnel Office (tel 0224 273500). Applications by letter with full CV including the names of three referees to the **Personnel Office, The University, Regent Walk, Aberdeen AB9 1FX** by 20 October 1989 quoting reference number LW/054. (1680)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
Department of Bacteriology
Infectious Disease Unit

LECTURER IN MOLECULAR MICROBIOLOGY
With an interest in Mycology

Applications are invited for this post created under the New Academic Appointments Scheme. The Lecturer will join and play a major role in a well-funded group concerned with the molecular biology of opportunistic fungal infection, at present focusing on Aspergillus fumigatus. It is intended that the appointee will play a leading role in the development of the group's activities.

Although some background in mycology is desirable it is not essential; scientists with experience in any aspect of molecular biology who are interested in fungal infections are encouraged to apply.

There will be a limited commitment to assist with a proposed M.Sc in Infectious Diseases.

Intended applicants are encouraged to contact either Dr J. Cohen (Head of Infectious Diseases, 01-740 3222) and/or Prof H Arst (Director of Bacteriology, 01-740 3243) to discuss the post.

It is hoped that the successful applicant will be able to take up the post on Jan 1st 1990 or soon thereafter.

Applications with full curriculum vitae (7 copies) together with the names, addresses and telephone numbers of three referees to be sent to the **Personnel Officer, Royal Postgraduate Medical School, Du Cane Road, London W12 0NN** from whom further particulars are available (tel: 01-740 3204). The closing date for the receipt of applications is 20th October 1989. Ref: AB08

(1677)A

DEPARTMENT OF MEDICAL GENETICS
UNIVERSITY OF TORONTO

Applications are invited for two tenure-track positions in the areas of developmental molecular biology in simple genetic systems, (e.g. yeast, *Drosophila*) or the physical chemistry of proteins Requirements include a Ph.D. degree or equivalent, and established excellence in research in one of these areas. The position will be located in the Medical Sciences Building on the downtown campus of the University of Toronto. The department has established strengths in the areas of prokaryotic and eukaryotic transcription, RNA splicing, genetic recombination, phage DNA packaging and morphogenesis, glycoprotein structure, human genetics, developmental biology, neurobiology, oncogenes and cancer.

The appointments will be at the Assistant Professor level and will begin after July, 1990 Salary will be commensurate with qualifications and experience

Letters of application together with a resume outlining current and long-term research objectives and the names and addresses of three referees should be sent to **Dr. Paul Sadowski, Chairman, Department of Medical Genetics, University of Toronto, Toronto, Ontario, M5S 1A8, Canada.**

Closing date for applications is December 15th, 1989.

The University encourages both men and women to apply for positions. (NW4307)A

FACULTY POSITIONS
Molecular, Cellular & Developmental Biology
University of Colorado, Boulder

This department is beginning a major expansion into new areas, with recruitment for a substantial number of new faculty At this time we are seeking to fill three positions over the next two years. We are most interested in candidates at the Assistant Professor level whose research deals with mechanisms of cell-cell communication, signal transduction, or cellular responses. However, we will also accept applications from exceptional individuals in other areas or at more senior rank. We will consider only candidates who have demonstrated outstanding research ability Other selection criteria will include teaching ability and interaction with colleagues. Candidates should have a resume, reprints, an outline of proposed research, and at least three letters of reference sent to Search Committee, Dept of MCD Biology, Campus Box 347, University of Colorado, Boulder, CO 80309. Dossiers must be complete by 15 November 1989, but earlier applications will be considered promptly.

The University of Colorado has a strong commitment to diversify. We are particularly interested in applications from women, ethnic minorities, and disabled individuals (NW4310)A

You have a Ph D in a relevant subject including Pharmacology, Neuroscience or Psychology and up to a maximum of 3 years postdoctoral experience

SYNTHELABO RECHERCHE (L E R S)
is looking for a

Research Scientist - Ph.D
C.N.S. Pharmacology

SYNTHELABO RECHERCHE (L.E R S) is the research division of the SYNTHELABO Group, a company dedicated to high level research and drug development.

The successful candidate will contribute to basic research and drug discovery programs aimed at the development of novel therapeutic agents for C N.S disorders including anxiety, affective disorders, psychosis and epilepsy

Excellent facilities are available for behavioural and neuro-pharmacological studies in rodents and other species Our laboratories are situated in the outskirts of Paris and a new research centre is nearing completion

Salary and conditions are those associated with a major, research-based pharmaceutical company.
A knowledge of French would be useful but is not essential although the successful applicant must be prepared to learn.

Please send your application in confidence to LBW, 5 rue Lebouteux, 75017 PARIS, France quoting 2152NA.

Chairperson, Lung Injury-Cell Biology Unit

The University of Calgary invites applications for Chairperson of this new research initiative, to be developed in the Faculty of Medicine The Chairperson will establish a multidisciplinary research focus to carry out fundamental biomedical research in the normal, developing and injured lung.

Qualifications include MD and/or PhD and demonstrated research achievements. The successful candidate must be a molecular or cell biologist with interest in function of the lung at the cellular and molecular level. Experience helpful in cell culture; gene expression, regulation, and cloning, inflammatory mediator control, epithelial/endothelial cell function, or immunological aspects of lung disease.

The Chairperson will be expected to make successful application to the Alberta Heritage Foundation for Medical Research for salary and research support.

In accordance with Canadian immigration requirements, priority will be given to Canadian citizens and permanent residents of Canada The University of Calgary has an Employment Equity Program and encourages applications from all qualified candidates, including women, aboriginal people, visible minorities, and people with disabilities.

Applications, including curriculum vitae and the names of three referees, should be submitted by November 30, 1989, to:

Dr. John Remmers, Faculty of Medicine, The University of Calgary, 3330 Hospital Drive N.W., Calgary, Alberta, Canada T2N 4N1.

PHLS CENTRE FOR APPLIED MICROBIOLOGY AND RESEARCH

Division of Biologics

MOLECULAR VIROLOGY GROUP

A position is available in a multidisciplinary research group studying the physical and antigenic structure of immunogenic viral proteins The successful candidate will be a member of a research team studying the structure and synthesis of the major immunogens of flaviviruses. Although experience in handling viruses, especially human pathogens, would be an advantage, such experience is not essential as extensive in house training will be given The appointment will be funded for two years in the first instance and will either be as Basic Grade Microbiologist (Salary scale £8,255 - £10,369) or as a Senior Grade Microbiologist (Salary scale £11,778 - £15,394) (under review) depending on relevant experience

National Health Service terms and conditions will apply.

Further details can be obtained from Dr J R Stephenson Tel (0980) 610391.

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wilts SP4 0JG, Tel (0980) 610391 ext 240, to whom completed forms should be returned by 13th October 1989 quoting Post No 0530 (1684)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Institute of Advanced Studies

DIRECTOR OF THE RESEARCH SCHOOL OF BIOLOGICAL SCIENCES

The University seeks to appoint a Director of the Research School of Biological Sciences to succeed Professor R O Slayter, FAA, FRS, AO, who has taken up appointment as Chief Scientist in the Department of the Prime Minister and Cabinet.

The Director of the School will be responsible through the Vice-Chancellor to the University Council for the operation and development of the School, for its leadership as an academic enterprise and for its administration and financial management Therefore, the University is looking to appoint a person with broad biological interests, who is active and eminent in research, preferably in an area that strengthens the School's current activities, and who has experience in science management and knowledge of science policy at University and government levels.

The Research School is a multidisciplinary institute for research and post-graduate training on fundamental biological problems, conducted in an environment that encourages work on especially challenging topics with long as well as short term approaches Currently nearly 70 academic staff, of whom 25 are tenured, with 6 graduate students, are organise into 9 research groups coverin areas of developmental and mol cular neurobiology, visual scie molecular and population g tics, plant molecular and cell logy, plant-microbe interacti plant environmental biology an ecosystems dynamics They ar supported by some 80 administra tive and technical staff

The successful candidate will b appointed a Professor of th University until retiring age, 6 years The term of office as Direc tor will be fixed by the Universit in consultation with the perso recommended Remuneration wi be, currently, A$67,831 p a a Professor, plus a Director's load ing of, currently A$6,675 p a

Those who may be interested i being considered for this appoint ment are invited to write to Th Registrar, Australian Nationa University, PO Box 4, Canberra ACT, 2601, Australia, from whom further information may b obtained. Further information i also available from Appointment (36926), Association of Common wealth Universities, 36 Gordo Square, London WC1H 0PF Th University reserves the right not t make an appointment or t appoint by invitation at any time

Closing date. *31 October 1989* Ref RB 14 9 1.

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER

(W6528)A

THE INSTITUTE OF CANCER RESEARCH

(University of London)

TECHNICIAN

CELL AND MOLECULAR BIOLOGY

A post is available in the Institute's Cell and Molecular Biology Section based in Fulham Road, London, SW3, to join a team studying membrane traffic in mammalian cells, in particular the structure and function of the endocytic pathway. The work will provide an opportunity to gain experience in a wide variety of cell biological techniques and is suitable for a graduate in biochemistry, biology or a related discipline. Experience of cell culture, immunology, virology, or molecular biology would be an advantage but is not essential

Salary will be in the range of £8,682 to £11,415 p a. inclusive

Applicants are advised that smoking is prohibited in the majority of the Institute's premises

Please forward C V., in duplicate, with the names and addresses of two referees to the Personnel Officer, The Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL, quoting reference number 9 89 T N 45 (1697)A

UNIVERSITY OF DURHAM

PROFESSOR OF PLANT SCIENCES

DEPARTMENT OF BIOLOGICAL SCIENCES

Applications are invited for the post of Professor of Plant Sciences in the Department of Biological Sciences at Durham University.

Professor D Boulter will retire in September 1991 and his successor will be appointed in the same field, so as to build upon the established reputation for science at Durham in Plant Molecular Biology and Plant Biochemsitry

The starting date will be 1 February 1991, or as soon thereafter as convenient.

Further particulars may be obtained from the **Registrar and Secretary (P), University of Durham, Old Shire Hall, Durham DH1 3HP,** to whom applications (twelve copies), including the names of three referees, should be submitted not later than Thursday 30 November 1989.

(Candidates outside the British Isles need submit one copy only.)

(1659)A

POSTDOCTORAL ASSOCIATE

A position is available for structural studies of actin and tubulin and their associated proteins using electron microscopy and image analysis. The candidate for this position should have experience in protein purification and preparation and electron microscopy A state-of-the-art facility for both electron microscopy and image analysis is available, and collaborations with other groups working on the cyto-skeleton will be possible. The laboratory is part of a newly established Center for Structural Biology, and the candidate will interact with x-ray crystallographers and others engaged in structural research. Send CV's and references to **Dr Edward H. Egelman, Dept. of Cell Biology and Neuroanatomy, Univ. of Minnesota Medical School, 321 Church St SE, Minneapolis, MN 55455.**

(NW4312)A

SENIOR FACULTY POSITIONS

BIOLOGICAL SCIENCES COLUMBIA UNIVERSITY

The Department of Biological Sciences, Columbia University, invites applications for senior faculty (full professor) positions Preference will be given to leading investigators in the areas of structural biochemistry and vertebrate developmental biology

The successful candidate will play a pivotal role in the current expansion of the Sherman Fairchild Center for the Life Sciences. Send inquiries by January 1, 1990 to **A. Tzagoloff or M. Levine, 600 Sherman Fairchild Center, Columbia University, New York, NY 10027**

Columbia University is an Equal Opportunity/Affirmative Action Employer Women and members or minority groups are especially encouraged to apply. (NW4305)A

UNIVERSITY OF EDINBURGH
Department of Biochemistry

RESEARCH ASSOCIATE POSITIONS in PROTEIN CRYSTALLOGRAPHY

Applications are invited for two postdoctoral research positions to work with Dr Lindsay Sawyer on the determination of protein structure by X-ray crystallography. The positions are available immediately, and will be paid at or nerar Point 2 of the PDRA 1A scale.

The first project (with Dr S. van Heyningen) concerns pertussis toxin, the major toxic protein from the bacterium *Bordetella pertussis*, which causes whooping cough. It is therefore of great interest to those wishing to prepare a better vaccine. This MRC grant is awarded jointly to the Department of Biochemistry in Edinburgh and to the Centre for Applied Microbiology and Research at Porton. The main aim is to determine the 3-dimensional structure of the protein, from crystals grown in Edinburgh. Use will probably be made of the synchrotron source at Daresbury to collect the X-ray data. There will also be some opportunity for conventional protein chemical experiments.

The second post is funded by SERC for work on the structure determinations of *Drosophila* alcohol dehydrogenase (with Professor Roser Gonzalez, Barcelona), a zinc-free enzyme quite distinct from that found in liver, and/or dehydroquinase (with Professor John Coggins, Glasgow), the third enzyme in the shikimate pathway. It is expected that the work will also involve use of the synchrotron source at Daresbury.

Suitable candidates should have a good honours degree and are expected to have completed their PhD in some aspect of (protein) crystallography before taking up the post, which is for 3 years from 1st October 1989, or as soon thereafter as is practicable.

Applicants should send a *curriculum vitae*, and the names and addresses of two referees to Dr L Sawyer or Dr Simon van Heyningen from whom further details on both positions can be obtained, at the **Department of Biochemistry, University of Edinburgh, Hugh Robson Building, George Square, Edinburgh EH8 9XD (031-667-1011 or LINDSAY@edinburgh.biovax)** as soon as possible. Please quote Reference No. 5710. (1718)A

STMH
ST. MICHAEL'S HOSPITAL

As a preeminent teaching facility, St. Michael's Hospital offers a caring and compassionate environment with a dedicated team of professionals. Our 701-bed progressive teaching facility, affiliated with the University of Toronto, is committed to maintaining high standards of health care through extensive research. To continue on that course, we require the expertise of an:

IMMUNOLOGIST, Ph.D.

A highly self-motivated individual, you will develop an independent research program using innovative approaches to address immunobiological mechanisms. Taking a proactive approach, you will initiate and develop projects as well as establish an externally-funded independent research program. Opportunities for collaboration extend to areas of platelet immunology, AIDS, haemophilia, blood transfusion serology, leukocyte function and membrane receptors.

A Ph.D. in Immunology or related field with at least 4 years' postdoctoral experience in Cellular Immunology, Immunohaematology or closely related area is required. Previous experience with flow cytometry, cell sorting, compliment, membrane receptor functions or platelet immunology is an asset.

Research experience in immunology together with a proven track record of success brings a competitive salary and benefits package. We invite interested applicants to submit a detailed curriculum vitae, a brief summary of current research activities, representative reprints and the names of three references to:
Dr. John Freedman, Department of Immunohaematology, St. Michael's Hospital, 30 Bond Street, Toronto, Ontario M5B 1W8

(NW4308)A

Swiss Federal Institute of Technology and University of Zurich, Switzerland

Full Professor of Toxicology and Head of the Section of Structural Toxicology

The position is open in September 1991. The section of structural toxicology includes laboratories for pathology, hematology, immunological toxicology and in vitro toxicology The successful applicant must have a firm record of research accomplishments in modern toxicology and is expected to collaborate closely with the sections of chemical, genetic and functional toxicology. He should have leadership qualities and some teaching experience in toxicology

For consideration, please forward your curriculum, including a list of your publications and reprints of your five most important publications, as well as the names of three referees to **Dr. Philipp U. Heitz, Chairman of the Search Committee, Institute of Pathology, University of Zurich, Schmelzbergstrasse 12, CH-8091 Zürich, Switzerland,** not later than January 15, 1990. (W6511)A

Director, Mt. Lake Biological Station and Professor of Biology

The Department of Biology of the University of Virginia proposes to appoint a tenured evolutionary biologist (Professor or Associate Professor) who will serve as Director of the Mt. Lake Biological Station. Mt. Lake has an established summer program of research and teaching, attracting researchers, faculty and students from around the nation The Station is located at 4000 feet in the Allegheny Mountains of Virginia. The successful candidate will (1) administer the academic program of the Station, (2) establish a personal research program in some aspect of evolutionary biology, (3) seek external support for the station, and (4) contribute to the teaching program of the Department of Biology. The closing date is January 15th or until the position is filled. Applications, including a curriculum vitae, a statement of purpose and career goals, and the names of three referees, should be sent to the **Chairman, Mt. Lake Search Committee, Dept. of Biology, University of Virginia, Charlottesville, VA 22901, USA.** *The University is an affirmative action/equal opportunity employer.* (NW4300)A

DEPARTMENT OF CARDIAC MEDICINE NATIONAL HEART AND LUNG INSTITUTE BRITISH POSTGRADUATE MEDICAL FEDERATION UNIVERSITY OF LONDON

A Post-Doctoral Research Assistant 1A

is required by Dr. P. H. Sugden to join a group investigating the hormonal regulation of protein synthesis in the heart. The successful applicant will investigate the mechanism of stimulation of cardiac protein synthesis by insulin in perfused hearts and isolated cardiac myocytes The position is suitable for a person with a background in biochemistry or an allied biological science. The post is financed by the British Diabetic Association and is available for 2 years. Starting salary. up to £12381 + £1650 London allowance

Written applications with full CV + daytime phone number and the names, addresses and telephone numbers of two referees should be sent as soon as possible to the **Personnel Office, National Heart and Lung Institute, Dovehouse St., London SW3 6LY** quoting reference no. CMD5/64 (1702)A

VIROLOGIST/ IMMUNOLOGIST

As part of the Sudbiotec consortium, Life Science Research — Roma Toxicology Centre (LSR-RTC) will be embarking on a major project which includes the safety assessment of monoclonal antibodies and other medicinal products derived from recombinant DNA technology.

We are seeking a Project Leader and qualified Support Staff for the development of this activity.

The team will be experienced in cell culture techniques and familiar with detection methods for viruses, retroviruses, transforming DNA and other foreign agents. The establishment and employment of a battery of tests will be required.

This position of responsibility provides an opportunity for both basic and applied research in the pre-clinical development of products derived from new biotechnologies.

LSR-RTC is housed in modern laboratories 20 km south of Rome. Interested candidates are asked to send their curriculum vitae by special delivery mail or telefax to:

Dr. Richard K. Haroz, The Managing Director
Life Science Research – Roma Toxicology Centre
Via Tito Speri 12
00040 Pomezia (Roma)
Italy
Fax No. 39 6 912 53 87
Tel. No. 39 6 912 03 51

(W6356)A

Postdoctoral Research Officer
Mammalian Developmental Molecular Genetics

A post-doctoral position for a period of up to 5 years is immediately available in new group within the established Division of Molecular Medicine headed by I James Scott The project is to study human and murine developmental malformations and aims to identify and clone the gene mutated in the human dysmorphology syndrome, Greig cephalopolysyndactyly syndrome (GCPS), using 'reverse genetic' strategies. The murine homologous mutant for GCPS, extra toes, will be used in interspecific crosses to generate a high resolution regional genetic map

The successful applicant will be employed in pulsed-field mapping, cloning fro PFG fragments, cDNA library construction, screening and sequencing.

Practical skills in molecular genetics are essential.

Informal inquiries to Martin Farrall, (01) 869 3244.

Salary will be at an appropriate point of the scale for non-clinical universi academic staff Application forms may be obtained from the Personnel Dept 0 869 3431 quoting ref 111/1/4280 Closing date for applications 20 October 1989

MRC Clinical Research Centre, Watford Road, Harrow, HA1 3UJ.

The MRC is an equal opportunity employer. (1661)A

THE UNIVERSITY OF LIVERPOOL DEPARTMENT OF IMMUNOLOGY

RESEARCH TECHNICIAN C

To work on a project funded by the North West Cancer Research Fund investigating functional and molecular aspects of human gamma/delta-bearing T cells. Previous experience in lymphocyte culture and cloning, flow cytometry or nucleic acid hybridisation techniques would be advantageous

Applicants should be qualified to B Tech National.

The post is tenable for one year in the first instance subject to annual review up to three years.

Salary in the range of £7,497-£8,645 per annum

Quote Ref· PER/115/N.

Closing date: Friday, 13th October, 1989

Application forms available from the **Director of Staffing Services**

UNIVERSITY OF LIVERPOOL
Department of Chemistry
Crystal Structure Determination with Synchrotron Radiation

Postdoctoral Senior Research Assistant

To work on an SERC funded project. Single crystal diffraction data is recorded on the Synchrotron Radiation Source at Daresbury Laboratory (18 miles from Liverpool) for zeolites, organic and organometallic crystals, too small for study with conventional X-ray sources; extension to proteins and/or even smaller crystals (<10 um) is planned Informal enquiries to Dr. M.M Harding.

Tenable for up to three years from 1st January 1990 Initial salary in the range £10,458 – £11,736 per annum.

Applications by c.v. with the names of three referees, should be received not later than 12 October 1989, by **The Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool, L69 3BX,** from whom further particulars may be obtained. Quote ref. RV/512

An Equal Opportunity Employer (1714)A

Post Doctoral Positions in Biochemistry and Molecular Biology

Two positions are available immediately to study the mechanism of action of specific deoxynucleotide metabolizing enzymes as well as the regulation of their genetic expression in eukaryotes and prokaryotes Gene isolation and amplification of their protein products will be required. Once obtained substrate and regulatory sites on the protein products will be determined by functional group specific reagents and affinity labels In addition site specific mutagenesis will be employed to establish the relation of structure to function in these enzymes Cloning and sequencing experience desirable. The research will be conducted in a well-equipped core facility Compensation from Health Research Inc dependent upon experience Send resume and three references to. **Dr. Frank Maley, Wadsworth Center for Laboratories and Research, Empire State Plaza, Box 509, Albany, NY 12201.** *An equal opportunity Affirmative Action Employer.* (NW4303)A

DEPARTMENT OF VISUAL SCIENCE, Institute of Ophthalmology, Judd Street, London, WC1H 9QS

Lecturer

Candidates with a proven record in research in scientific topics relevant to investigative ophthalmology, visual neurobiology or visual psychophysics will be considered. The Department has a rapidly expanding externally funded research programme and with recent new appointments to staff and the close links with Moorfields Eye Hospital, provides an ideal environment for those wishing to develop an independent research career in ophthalmology or vision in the UK. The starting date is negotiable. Salary within the scale £15,105-£19,310 or £20,270-£22,910 p.a. plus £1650 London Allowance.

Technical Research Officer

This post is for candidates with experience in biomedical laboratory science to assist the Head of Department in the day to day running of the laboratories, monitoring accounts and processing orders. It will carry considerable responsibility and require both technical and administrative expertise. The starting date will be Oct/Nov 1989. The salary will start from £15,623 (plus £1,267 London allowance) on the scale £14,444-16,897

Applicants should send a full curriculum vitae with names of two referees to Professor A M Silito at the address above from whom further details can be obtained (01-387-9621 x258) (1729)A

nature

the widest international selection of jobs in science — EVERY WEEK

AFRC Institute for Grassland and Animal Production

Joint Agriculture and Environment Programme

Herbivore/Plant Interactions

Applications are invited for two temporary Higher Scientific Officers to join an IGAP/Oxford University multidisciplinary research project entitled "Selective grazing by sheep and goats in a heterogeneous environment".

The two HSOs are required at the Hurley Research Station and the Welsh Plant Breeding Station and the postholders will be expected to develop their own programme of research within the given remit as well as to collaborate fully in the integrated project.

Post 1 Plant Nutrition and Growth Department — Hurley

(Dr A J. Parsons/P D Penning)
The postholder will study the foraging and intake behaviour of domestic herbivores in a heterogeneous plant species environment and its impact via vegetation dynamics on the stability and composition of the sward and its diet.

Qualifications
First or upper second class honours degree in a biological or agricultural sicence with at least two years' post-graduate experience Preference will be given to candidates with experience in behavioural ecology, plant vegetation dynamics, mathematical modelling and real time computing

Post 2 Grassland Agronomy & Ecology Department — Welsh Plant Breeding Station

(Ref 89/34) (Dr G Moseley)
The postholder will study the role of chemical, physical and anatomical characteristics of forage plants, and the spatial geometry of swards in determining intake and preference by grazing animals.

Qualifications
First or upper second class honours degree in a biological or agricultural science with at least two years' post-graduate experience. Preference will be given to candidates with experience in behavioural ecology and plant chemistry

Terms and Conditions
Salary scale (HSO): £10,678 – £14,909
Non-contributory pension scheme
Annual leave: 25 days plus 10.5 Public and Privilege holidays per annum

Written requests for application forms and further particulars should be made to the **Personnel Officer, AFRC Institute for Grassland and Animal Production, Welsh Plant Breeding Station, Plas Gogerddan, Aberystwyth, SY23 2EB.** Closing date 27th October 1989 (1703)A

MOLECULAR BIOLOGY/BIOCHEMISTRY

The Department of Chemistry and Biochemistry at the
UNIVERSITY OF NOTRE DAME
has a tenure-track faculty position available at the level of

ASSISTANT PROFESSOR

Qualified applicants may be considered for a more senior level of appointment. Preference will be given to applicants with research interests in the general areas of molecular biology and/or biological molecular structure (including protein crystallography). The Department and College offer outstanding facilities and technical support. Current faculty and staff in molecular biology, biochemistry, and associated fields provide a wide-ranging base for interaction and support in the development of a vigorous research program. Teaching responsibilities will be in the area of molecular biology or biochemistry

Interested individuals should submit a current curriculum vitae including bibliography, a statement of research interests, and three letters of reference to· **Molecular Biology/Structure Search Committee, Department of Chemistry and Biochemistry, University of Notre Dame, Notre Dame, Indiana 46556** The deadline for receipt of all materials is November 15, 1989

The University of Notre Dame is an Affirmative Action/Equal Opportunity Employer. (NW4298)A

DEPARTMENT CHAIR OF BIOLOGICAL SCIENCES

STATE UNIVERSITY OF NEW YORK AT BUFFALO

The Department of Biological Sciences at the State University of New York at Buffalo is searching for a Full Professor to build an outstanding research program and assume the position of Department Chair within one year of arrival. The starting date is negotiable and the successful candidate could begin as soon as September 1990. The Department presently consists of 27 full-time tenure-track faculty with research strengths in the areas of Cell and Molecular Biology, Genetics and Developmental Biology, Cellular Physiology and Ecology. We are committed to excellence in very active undergraduate and graduate programs. Our graduate program currently consists of approximately 50 full-time students. In addition to those who are supported by external grants, many of our graduate students are supported by state funds.

Superb core facilities are available to the Department for DNA and peptide synthesis and sequencing, computer structure modeling, monoclonal antibody production, animal facilities and state-of-the-art microscopy. In addition the Department has in place a well trained staff who operate and maintain the electron microscopy lab, greenhouse, electronics shop, machine shop and scientific illustration and photography lab.

We seek an outstanding scientist with demonstrated excellence in research and a genuine interest in quality graduate and undergraduate education. It is expected that the candidate will vigorously pursue an active research program, promote Departmental and interdepartmental interactions among the faculty, provide scientific, educational and administrative leadership and continue the development of the Department towards its goal of becoming one of the leading departments in the country. The University has committed considerable resources to this goal and will provide superb setup and operating funds. The opportunity to hire a considerable number of new tenure-track faculty will be available to the new chair.

Submit nominations and applications including curriculum vitae, summary of research interests and names, addresses and telephone numbers of four references to **Dr. Ronald Berezney, Department Chair Search Committee, Department of Biological Sciences, State University of New York at Buffalo, Buffalo, NY 14260.** Deadline for receipt of completed applications is December 1, 1989, or until a suitable candidate is identified. *SUNYAB is an Affirmative Action/Equal Opportunity Employer.* (NW4304)A

ASSISTANT PROFESSOR

NORTHWESTERN UNIVERSITY

The Department of Biochemistry, Molecular Biology and Cell Biology seeks outstanding candidates for a tenure-track assistant professor position. Individuals with strong research interest in cell biology, including intracellular transport processes, membrane-cytoskeleton interactions, regulation of cell growth and differentiation, and cell-cell communication and signalling are encouraged to apply. Exceptionally qualified candidates in other areas will also be considered, as the abilities of the applicant are more important than the particular area of research interest. Research programs in the Department include developmental biology, genetics and molecular biology, immunology and virology, and structural biology.

Candidates should submit curriculum vitae, a list of publications, copies of preprints, a statement of future research objectives and letters of reference from three persons knowledgeable of the candidate's research and teaching abilities to: **Dr. Kelly E. Mayo, Faculty Search Committee, Department of Biochemistry, Molecular Biology and Cell Biology, Northwestern University, 2153 Sheridan Road, Evanston, IL 60208.**

Hiring is contingent upon eligibility to work in the United States. AA/EOE.

(NW4296)A

KING'S COLLEGE LONDON
BIOMOLECULAR SCIENCES DIVISION
POST-DOCTORAL RESEARCH POST

We are seeking a molecular geneticist to work on a three-year Asthma Research Council-funded Project on the receptors for human immunoglobin E. This work will complement continuing studies on the receptor binding sites on human immunoglobulin E (Helm *et al*, Nature 331, 180, 1988; Vercelli *et al*, Nature 338, 649, 1989) making use of recombinant DNA technology, molecular modelling and monoclonal antibodies. Candidates should have a PhD and be able to start work before 1 January 1990.

Starting salary up to £13,386 inclusive.

Applications with the names of two referees should be sent to **Mr D.M. Drummie, King's College London, 26-29 Drury Lane, London WC2B 5RL.** Enquiries may be made to Dr B.J. Sutton or Prof H.J. Gould on 836-8851. (1700)A

THE INSTITUTE FOR ADVANCED STUDY

Will have several openings for members in theoretical physics and astrophysics for the academic year 1990-91. The positions are at a postdoctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of astrophysics, elementary particle physics, mathematical physics, general relativity and statistical mechanics. Preference is given to candidates who have received their Ph.D. within the last year or two. Postdoctoral members frequently collaborate with each other, with faculty members at the Institute of Princeton University, and with researchers at other institutions. Appointments are usually for two years and support is typically full salary for postdoctorals and half salary for more senior persons Women and minorities are encouraged to apply. For more information write to **Michelle Sage, School Administrative Officer, School of Natural Sciences, Institute for Advanced Study, Princeton, New Jersey 08540.** Applications should be received by December 15, 1989. (NW4210)A

FACULTY POSITIONS IN MOLECULAR PHARMACOLOGY

The Department of Pharmacology, University of Missouri-Columbia (UMC), invites applications for tenure-track positions at the assistant, associate, or full professor levels focusing on the application of molecular biology to analysis of significant problems in pharmacology. Research areas of interest include but are not limited to: structure, function and regulation of receptors, membrane transport proteins, and ion channels; molecular mechanisms of transmembrane signalling, and, actions of drugs, neurotransmitters and growth factors. Emphasis for one of the positions will be in the areas of neuropharmacology/CNS pharmacology Successful candidates are expected not only to have a strong record of research accomplishments but also to participate in the teaching of medical and graduate students. Please send curriculum vitae, a brief description of research plans, and the names of three references to: **Dr. Hyun Dju Kim, Professor and Chairman, Department of Pharmacology, University of Missouri-Columbia, School of Medicine, M517B Medical Sciences Building, Columbia, MO 65212.** *An Equal Opportunity/Affirmative Action Employer.* (NW4293)A

FACULTY POSITIONS DEVELOPMENTAL BIOLOGY/GENETICS

PRINCETON UNIVERSITY

The Department of Biology at Princeton University invites applications for tenure track positions in the area of Developmental Biology and Developmental Genetics. Candidates should have a Ph.D. degree and research experience in the development of eukaryotes. Appointments at either the junior or senior level will be considered. Applicants should send a curriculum vitae, the names of at least three referees and a summary of research interests to:

Developmental Biology Search Committee,
Department of Biology,
Princeton University,
Princeton, NJ 08544

Princeton University is an Equal Opportunity/Affirmative Action Employer. (NW4280)A

At the heart of health

We are ceaselessly imagining and developing products that better serve humankind and the plant and animal worlds Our overriding duty is to ensure every individual's safety and protect the environment Our Group, present on the four corners of the globe, derives its strength from research Its vitality is evident in how well it responds to customer expectations and the requirements of the marketplace

RESEARCH CHEMISTRY ENGINEERS
with Ph. D.

We would like to meet Research Chemistry engineers with à Ph D in organic chemistry, to participate, within our Agrochemical Division, in the elaboration of new crop protection compounds
These posts offer excellent opportunities for establishing an innovative research prcgram, thanks to your experience and knowhow
The candidates should show creative approach, initiative and capacity to motivate a research team Fluent English required Ref. 115/N

ENTOMOLOGIST

We are seeking for an agro engineer or a Ph D specialized in zoology, with or without experience, to participate in our program of research for applied biology in suburban Marseilles (France)
You will be responsible for leading biological assays and tests with a view to selecting new molecules synthetized within our Group research teams, in the crop protection field
If you are interested in chemical structures / biological activities, you should send a curriculum vitae Ref 114/N

Applications are invited with full cv, publication list and covering letter to ROUSSEL UCLAF, Service Recrutement des Cadres, 35 boulevard des Invalides, 75007 Paris (France)

ROUSSEL UCLAF

CURRICULUM

UNIVERSITY OF BATH
Department of Biochemistry

POSTDOCTORAL POSITIONS

The Department of Biochemistry at Bath University has several vigorous research programmes in which protein structural studies and molecular biological techniques provide a unifying force The University is in the process of establishing a new Biophysics Group within the Department that provides X-ray crystallography, protein crystallisation laboratories and enhanced facilities for protein structural analysis and molecular modelling

Two post-doctoral positions are currently available both of which provide opportunities for interactions with the new Group —

1 Within an MRC AIDS Directed Programme to work in expression and structural characterisation of HIV endonuclease/integrase The aim of the project is to develop expression systems which will allow us to obtain purified endonuclease in an active form Purification of the endonuclease will be followed by structural and mechanistic studies with the aim of providing information for the design of new therapeutic compounds
Applicants should have a background in molecular biology, preferably with experience in expression systems Experience of site-specific mutagenesis would be an additional advantage For further details telephone Dr David Hough (826687) or Dr Michael Danson (826509) Reference 89/290

2 Within the Insect Neuroscience Group as part of a long term collaboration with Shell Research on insect nicotinic acetylcholine receptor Cloned subunits of this receptor are being expressed with a view to obtaining protein for structural analysis The appointee would be involved firstly with purification of the expressed protein and then with attempts to obtain structural data from spectroscopic analysis Applicants should have a background in protein chemistry
Informal enquiries may be made to Professor G G Lunt, tel Bath (0225) 826568 or Dr A Wolstenholme tel Bath (0225) 826826 ex 5507 Reference 89/291

The posts are available immediately for a period up to three years at a starting salary of £12381 p a

Application forms may be obtained from the **Personnel Office, University of Bath, Claverton Down, BATH, BA2 7AY** or tel. BATH (0225) 826095 quoting appropriate Reference Number Closing date 11th October 1989.

(1681)A

Fortran Programmer/ Database Administrator
Scientific Databases Group

Daresbury Laboratory provides two major national research facilities – a Synchrotron Radiation source providing high brilliance photon beams at a wide range of energies and a 20 MV Tandem Van de Graaff Accelerator for heavy ion nuclear structure research. In addition, it provides a wide range of computing facilities.

The Job

A vacancy exists in the scientific database group for a programmer/database administrator in the Chemical Databank System section. The section is responsible for development and operation of a service providing networked access to a number of scientific databases. Although primarily working on developing and mounting database systems, the person appointed will also be expected to provide support to the user community, which is largely based in academic institutions.

The Person

Applicants must have a scientific background as well as FORTRAN programming experience. Previous database experience is desirable but not essential. The successful candidate will have the ability to understand and learn new ideas quickly and an ability to communicate with scientists from a range of disciplines.

Appointments will be made at Scientific Officer or Higher Scientific Officer grade. Salary will be in the range £9,131 – £14,909, further increments are available depending on performance, and there is a non-contributory pension scheme. A contribution towards relocation expenses may be available.

Application forms can be obtained by quoting reference no. DL124 from The Personnel Officer, Science and Engineering Research Council, Daresbury Laboratory, Warrington WA4 4AD
Telephone (0925) 603467 (24 hours).
Closing date: Friday 13th October 1989

Daresbury SCIENCE & ENGINEERING RESEARCH COUNCIL

DREXEL UNIVERSITY
DEAN, COLLEGE OF SCIENCE
SEARCH REOPENED

Drexel University invites nominations and applications for the position of Dean of the College of Science. Drexel is a private nonsectarian institution which emphasizes programs in the sciences and engineering and has a tradition of excellence in cooperative education. It enrolls over 12,000 graduate and undergraduate students in its seven colleges and has an attractive modern campus in the University City area of Philadelphia. The College of Science includes the departments of Bioscience and Biotechnology, Chemistry, Mathematics and Computer Science, Nutrition and Food Sciences, and Physics and Atmospheric Science, as well as associated programs in Teacher Preparation, Biomedical Science and Environmental Sciences. With a faculty of 89, an enrollment of over 550 science majors, and external research funding over $3.0 million per year, this growing college seeks a dynamic and innovative Dean.

The Dean is the college's academic leader, chief administrator and prime advocate to the University. The Dean reports directly to the Vice President for Academic Affairs and is responsible for administering all aspects of the college, for evaluating all academic programs and faculty, and for providing leadership and guidance in recruitment, research, curriculum, and resource development.

The successful candidate must have an earned doctorate in an appropriate science discipline, demonstrated management experience, and a record of teaching, research, and scholarly achievement appropriate for a tenured Professorship in one of the departments of the college. Appointment is expected on or after July 1, 1990. Salary is highly competitive. Review of candidate and nominee materials will begin December 1, 1989. Letters of application, including a resume, or letters of nomination, should be sent to.

Prof. Stanley Segall, Chairperson, Dean of Science Search Committee, c/o The Office of The Dean of Science, Drexel University, Philadelphia, Pennsylvania 19104.

DREXEL UNIVERSITY IS AN EQUAL OPPORTUNITY AFFIRMATIVE ACTION INSTITUTION AND INVITES APPLICATIONS FROM MINORITIES AND WOMEN. (NW4286)A

DIRECTOR
LAMONT-DOHERTY GEOLOGICAL OBSERVATORY OF COLUMBIA UNIVERSITY

Columbia University invites applications and nominations for the Directorship of Lamont-Doherty Geological Observatory. The Director must be capable of exerting strong intellectual leadership in the Earth Sciences. Scholarly eminence and capabilities in administration, future planning and fund raising are required.

L-DGO is an institute of Columbia University dedicated to graduate education and research in the earth, atmospheric and ocean sciences. The Observatory is located on an historic estate on the shores of the Hudson River one-half hour from the main campus of the University. Research programs are conducted by over 600 scientists, staff and graduate students.

Applications or nominations should be submitted by December 1 to:

Dr. Charles H. Langmuir, Chairman
Search Committee
Lamont-Doherty Geological Observatory
of Columbia University
Palisades, New York 10964

Columbia University is an Equal Opportunity/Affirmative Action Employer. (NW4302)A

The Queen's University of Belfast

LECTURESHIP IN GEOLOGY

Applications are invited for a lectureship in Economic Geology in the Department of Geology, newly established to enhance the Earth Resource work of the Department Applicants with research expertise in any relevant field will be considered but preference may be given to those with experience in exploration mineralogy, petrology or geochemistry. The successful applicant will be expected to be aware of the economic implications of earth resource exploitation and will be encouraged to liase with industry. The post is available from 1 January 1990, or such other date as may be arranged

This lectureship is available under the initiative of the Universities Funding Council's New Academic Appointments Scheme intended to create career opportunities for young academic staff at an early stage in their careers. Although the UFC has indicated that the average age should preferably be under 35 there is no absolute age limit so that applications may be considered from those, appropriately qualified, who have returned from a break in their careers

Salary scale Lecturer A: £9,816 – £15,372 (minimum at age 27 or over £12,381), *or* should a suitably qualified applicant be presented, Lecturer B: £16,014 – £20,469, with eligibility for USS. Generous relocation package as appropriate

Further particulars (please quote ref 89/N) may be obtained from the **Personnel Officer, The Queen's University of Belfast, Northern Ireland, BT7 1NN** Closing date. 20th October 1989 The University is an Equal Opportunity employer. (1721)A

UNIVERSITY OF ROCHESTER
FACULTY POSITION
PLANT MOLECULAR/CELLULAR/DEVELOPMENTAL BIOLOGY

The Department of Biology of the University of Rochester is committed to a major faculty recruiting effort over the next few years to strengthen its representation in the plant sciences. One tenure-track position will be open July, 1990. We anticipate an assistant professorship, but in an exceptional case, a more senior person could be appointed. The successful candidate will be expected to develop an excellent research program in some aspect of plant molecular, cellular or developmental biology and to be committed to high quality undergraduate and graduate education.

The Department of Biology has excellent support facilities for molecular, cellular and developmental biology. Salaries are competitive, as are "start-up" funds for new faculty. Review of candidates will begin 1 November and will continue until an appointment is made Interested candidates should send *c v.*, a statement of research interests, reprints, and three letters of recommendation to **Chair, Plant Biology Search Committee, Department of Biology, University of Rochester, Rochester, NY 14627.** *The University of Rochester is an Affirmative Action/Equal Opportunity Employer. Women and minorities are encouraged to apply* (NW4317)A

MOLECULAR GENETICIST

The Department of Pathology at The Children's Hospital, is searching for a qualified individual to supervise a service laboratory in molecular genetic diagnostic testing. For the appropriate candidate, an academic appointment would be available in the University of Colorado School of Medicine, along with opportunities to pursue research efforts Applicants must have a Ph.D. in molecular biology or a related field, have experience in molecular genetic testing, and be eligible for board certificates in Molecular Genetics by the American Board of Human Genetics on or before June 1990

Send curriculum vitae, a statement of career objectives and current and/or planned research, and the names, addresses and phone numbers of three individuals who have agreed to act as references to: **Dr. Vincent Wilson, Director of Molecular Genetics, Pathology Department, The Children's Hospital, 1086 E. 19th Ave., Denver, Co 8021B-1088** EOE M/F (NW4309)A

The Children's Hospital

Post-Doctoral Fellow - Immunogenetics

The British Columbia Transplant Society, and the Department of Pathology, University of British Columbia, have a full-time position available for a post-doctoral fellow in a newly-established Multiorgan Transplant Programme serving the province of British Columbia. The successful candidate will be working in the Histocompatibility/Immunogenetics section of the Transplant Immunology Laboratory, Division of Hematopathology, Vancouver General Hospital, and in the Immunobiologics Laboratory within the Transplantation Immunobiology Research Centre, the Jack Bell Research Institute. The appointment will be on a contractural basis and is renewable. The possibility to convert to a full academic appointment exists. Candidates must hold a PhD degree or equivalent with experience in fields relevant to the discipline. They should be well versed in techniques of molecular immunology and genetics, nucleic acid and protein chemistry and have experience in computer manipulation and analysis of experimental data. Experience in animal models would be desirable. Candidates should be able to initiate grant-supported research within an integrated research programme. Individuals interested in this position should send their application, curriculum vitae and references by **November 30, 1989** to:

Dr. P. A. Keown, Director
British Columbia Transplant Society
Vancouver General Hospital,
Heather Pavilion, D-10, Room 19
855 West 12th Avenue
Vancouver, B.C. V5Z 1M9 Canada

This advertisement is directed first to Canadian citizens and permanent residents. Salary will be commensurate with qualifications and experience. (NW4314)A

Vancouver General Hospital
British Columbia's Health Sciences Centre

D.J. van der Have B.V.,

a Dutch plant breeding company with a strong international position in several agricultural crops, offers within the scope of a genetic manipulation programme on sugar beets (University of Leiden and Van der Have Breeding Station, NL; University of Picardie, Amiens, F.) a

Postdoctoral position in Plant Genetic Engineering

The successful candidate will work in an efficient dynamic team in **Amiens** (= 100 km north of Paris). He will have proven experience with Agrobacterium transformation technology and basic molecular techniques for the characterization of transgenetic materials.

This is a two years appointment; salary will be according to qualifications and experience.

Applications with CV and the names of two referees should be submitted to:

Dr. A.M.M. de Laat,
D.J. van der Have B.V.,
P.O. Box 1,
4410 AA RILLAND, the Netherlands
(tel. (31) 1135 – 2151).

(W6362)A

UNIVERSITY OF COPENHAGEN
FACULTY OF NATURAL SCIENCES

Applications are invited for a

CHAIR (Professorship)

in Freshwater Biology
at the Freshwater Biology Laboratory of Copenhagen University from the 1st of July 1990.

The professor will be appointed a Civil Servant under the Ministry of Education and Research. The annual salary is approximately 360.00 Danish Kroner.

The laboratory covers research within zoological, botanical and biological freshwater biology

The professorship covers botanical-chemical aspects in freshwater and brackish ecosystems. An essential prerequisite is a documented knowledge of ecophysiological problems within various types of autotrophic aquatic organisms.

The professor will participate in the laboratory's teaching at all levels. The language of instruction is Danish but English might be accepted for a period of two years from appointment.

Applications should include three copies of all scientific publications and other materials that the applicant wishes to have considered together with a list of all submitted material

Information concerning the applicant's teaching experience must be included. The Committee on Teaching and Curricula (Studienævn) will be asked to evaluate the applicants teaching experience.

Evaluating of the applicants qualifications will be undertaken by a specially appointed scientific committee The committee's report will unabridged be sent to all applicants.

Applications are to be addressed to **Her Majesty the Queen of Denmark** and sent to **The Faculty of Natural Sciences, Panum Instituttet, Blegdamsvej 3, DK 2200 Copenhagen N, Denmark.** Closing date for receipt of applications is the 1st of November 1989.

It is expected that the Freshwater Biology Laboratory (now in Hillerød, North Sealand) will be merged with the Marine Biological Laboratory (Elsinore) under the formation of a Hydrobiological Institute.

(W6355)A

Pfizer

MRC Clinical Research Centre, Watford Road
Harrow, HA1 3UJ, Middlesex

We have two vacancies within our Retrovirus Research Group which are to be funded by Pfizer UK:–

1) Post-doctoral Fellow — Virology

A Post doctoral Fellow is recuired to work on a project developing new anti-HIV compounds in close collaboration with scientists at Pfizer The post will involve the development of new assay systems as well as supervising two Scientific Officers who will also perform the screening of compounds for anti-HIV activity. The post will involve working with HIV in containment level 3 and would be suitable for a post-doctoral fellow with experience in virological cell culture and basic molecular techniques and will provide ample opportunity to develop and pursue original research proposals with the main programme of the CRC Retrovirus Research Group where the post will be based.
Salary will depend on previcus experience and be on an appropriate point on the scale for non-clinical university academic staff. Ref: RRG/P/1

2) Scientific Officer

A Scientific Officer is required to work on the above project involving testing various compounds for anti-HIV activity
Applicants should have a virological background and should be conversant with containment level 3 working practices.
Salary will depend on previous experience and be within the range £11,125-£13,818 inclusive of London weighting and a non-superannuable supplement Ref RRG/P/2
Application forms and further details for both posts are available from the **Personnel Dept 01.869.3411** quoting the appropriate reference. Closing date for completion applications is 19th October 1989.
The Medical Research Council is an Equal Opportunity Employer (1720)A

JOHN INNES INSTITUTE

Department of Cell Biology

Applications are invited for this principal investigator post in the Plant Cytoskeleton Group. An experienced project leader, with a clear record of imaginative and innovative thinking, required to manage, inspire and lead a group of scientists working on the plant cytoskeleton The work will involve a wide range of knowledge and expertise ranging from high resolution structural studies to biochemistry to molecular biology. The post-holder is likely to have considerable experience as a group leader and an international reputation in the field of plant cell and developmental biology.

The appointment will be on the UG7 grade £17,360 to £22,606 Candidates should have a PhD and considerable experience in the plant cytoskeleton field Non contributory superannuation.

Applications with full particulars, CV, and the names of two referees should be sent to the Personnel Officer, John Innes Institute, Colney Lane, Norwich NR4 7UH quoting Ref. No. CB/346, to arrive not later than 12th October 1989.

The John Innes Institute is an Equal Opportunities Employer and is associated with the AFRC Institute of Plant Science Research (1679)A

POSTDOCTORAL RESEARCH ASSOCIATE

with a MD or a PhD in a biological science to study the molecular biology of Deinobacteriaceae. Demonstrated expertise in DNA sequencing and Deinobacterial molecular genetics required. Minimum salary, $19,600/yr (40 hrs/wk).

Please send CV and three references to:

John D. Shelburne, M.D., Ph.D. Professor and Chairman Pro Tem Department of Pathology, Box 3712 Duke University Medical Center Durham, North Carolina 27710.

If not a United States citizen, indicate your current visa status. (NW4291)A

POSTDOCTORAL (Ph.D.) FELLOW

Postdoctoral (Ph D) Fellow with interest in fibronectin, cell adhesive proteins or integrins

Send resume to: Dr. W J. Martin, Indiana University Medical Center, 1001 W 10th St, OPW 425, Indianapolis, IN 46202-2879 (NW4313)A

MONASH UNIVERSITY

MELBOURNE, AUSTRALIA

CHAIR OF MICROBIOLOGY

Applications are invited for appointment to a Chair of Microbiology The Chairman of the Department is Professor S Fame who retires at the end of 1991; Professor E G Westaway, who holds a personal Chair, retires at the end of 1989. The Department is in the Faculty of Medicine and is responsible for the teaching of microbiology to science and medical students. The Department offers second and third year undergraduate courses in the Faculty of Science as part of the Bachelor of Science degree, with a further year's study for the degree of BSc with Honours in Microbiology In addition, the Department is a major contributor to the Master of Biotechnology degree course. Currently, 24 post-graduate students are engaged in studies leading to the award of MSc or PhD degrees. All teaching in science is at the main Monash campus, where the Department occupies a well-equipped building. The Department's major contribution to the medical undergraduate course is in the fourth year at the Monash Medical School, Alfred Hospital, and represents about 30 per cent of the total teaching commitment of the Department. A postgraduate degree in Venereology is also presented.

The Microbiology Department has a strong commitment to research and an established reputation in the following areas: medical microbiology and microbial pathogenesis including molecular aspects of infection and immunity, molecular virology including viral gene expression, molecular microbiology including microbial genetics, microbial physiology and biotechnology

Applicants should be distinguished microbiologists who have established research records and have made significant contributions in one or more of the research areas of the Department They should also be experienced in teaching microbiology at undergraduate and postgraduate levels. The appointee will be expected to assume the Chairmanship of the Department within a reasonable period of time.

Salary. A$63,919 per annum. Superannuation, travel and removal allowance, and temporary housing assistance.

Information on application procedure and further particulars may be obtained from the Registrar, Monash University, Clayton, Victoria 3168, Australia, or from Appointments (36931), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF. Enquiries about the Department should be directed to Professor S Faine or to Professor E G Westaway. Applications should reach the Registrar not later than Friday 15 December 1989 Council reserves the right to make no appointment or to appoint by invitation at any stage.

AN EQUAL OPPORTUNITY EMPLOYER (W6527)A

THE UNIVERSITY OF SYDNEY

Australia

No smoking in the workplace is University policy.

LECTURESHIP IN MOLECULAR BIOLOGY

Department of Biochemistry

(Reference No. 36/01)

Preference will be for someone with an active research interest in eukaryotic molecular biology or structural aspects of nucleic acids Duties will consist of teaching and research Current research in molecular biology concentrates on (i) bacterial chromosome replication and cell division and (ii) human inherited diseases. In addition, the research interests of several members of staff impinge heavily on molecular biology eg site-directed mutagenesis of enzymes and DNA-protein interactions Excellent facilities for research are available With the approval of the University, staff with the rank of lecturer and above may undertake limited consulting work

The successful applicant will commence duties as soon as possible after June 1990.

Closing: 1 November 1989

Salary: A$31,259–A$40,622 per annum

Further general information is available from Appointments (36921) Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

Applications, quoting reference number, including curriculum vitae, list of publications and the names, addresses and FAX numbers of three referees, to the Registrar, Staff Office, University of Sydney, NSW 2006, Australia, from whom further information is available (FAX +612 692 4316).

The University reserves the right not to proceed with any appointment for financial or other reasons

Equal employment opportunity is University policy (W6517)A

PAISLEY COLLEGE

A Scottish Central Institution

Department of Civil Engineering
LECTURER 'A' IN GEOLOGY

Paisley College is a major degree awarding institution funded by the Scottish Education Department with some 3,000 full-time equivalent students on vocationally orientated degree and honours degree courses.

Applications are invited for the post of Lecturer in the Department of Civil Engineering (Geology Section) to commence in December 1989. The post will involve the teaching of Geology to 1st and 2nd year BSc levels in the School of Science and Technology. Applicants should have an honours degree in Geology and wide interests to be able to teach most aspects of Geology. Teaching and research experience would be advantageous.

Salary Scale: £10,935 – £16,260 (bar) – £19,623 pa

Application forms and further details may be obtained from the **Personnel Office, Paisley College of Technology, High Street, Paisley PA1 2BE** (Tel No. 041-887 1241 ext 234) to which completed applications should be returned by Monday 16th October 1989. (1715)A

University of Nottingham, Department of Physics

READERSHIP

Applications are invited for a Readership to be established in the area of nuclear magnetic resonance spectroscopic imaging and biophysics. It is intended that this post would strengthen the existing magnetic resonance imaging group led by Professor P. Mansfield, F.R.S., expanding its expertise and interests in the field of localised biological and medical spectroscopy.

Major new initiatives for high field imaging and spectroscopy are currently under consideration which will consolidate the existing and planned new equipment in a new building. Existing equipment comprises an NMR microscope based on an 11.7 T, 89 mm bore magnet, a home-built 0.5 T whole body echo-planner imaging machine with various supporting computer and display systems.

The planned new equipment includes a high field whole body magnet together with state-of-the-art electronics, computing and display facilities to be assembled in-house.

The person sought will have international eminence in biological spectroscopy with an established track record in fund raising. He will be expected to lead the spectroscopy part of the group's research programme and participate generally in the development of new imaging and spectroscopy imaging techniques. He will also be expected to participate fully in the undergraduate teaching programme in the Physics Department.

Applicants should have a good honours degree in physics or biophysics, or equivalent, with experience of teaching.

The salary will be in the range £21,489–£24,285 pa

Application forms and further particulars may be obtained from the **Personnel Officer, University of Nottingham, Nottingham NG7 2RD** (tel 0602 484848 ext 3355) to be returned not later than 20 October 1989. Ref. No. 1278. (1693)A

Coleg Prifysgol Cymru
Aberystwyth
The University College of Wales

RESEARCH APPOINTMENTS IN BIOCHEMISTRY

Applications are invited for the following research posts in the Department of Biochemistry.

POST-DOCTORAL RESEARCH FELLOW (Molecular Biology)

A three year appointment commencing January 1990. The project, funded by AFRC, involves cloning and sequencing the genes for components mediating protein translocation across biological membranes. Experience of working with DNA and of molecular biology will be an advantage. Salary on the Grade 1A Scale £10,458 to £16,665 per annum. Informal enquiries to Dr M A Kaderbhai (Tel: 0970-62311, Ext. 2294).

RESEARCH ASSISTANT

A three year appointment to work with Dr Shirazi-Beechey and Professor R B Beechey on a Tenovus funded project concerning biochemical changes associated with the development of cancerous conditions in the human colon Applicants should have a degree relating to physiological biochemistry/cell biology Salary on the Grade 1B Scale £9816 to £10,458 per annum. Informal enquiries to Dr Shirazi-Beechey on 0970-622291

Application forms and further particulars from the Staffing Officer, The University College of Wales, Old College, King Street, Aberystwyth, SY23 2AX (Tel: 0970-622054). Closing date for applications 8 November 1989. (1725)A

UNIVERSITY COLLEGE LONDON

RESEARCH ASSISTANT

Applications are invited for a 3-year appointment as a Research Assistant to work on a SERC Image Interpretation Initiative project investigating the perception of 3D shape from shading and texture. Applicants should have a doctorate or research experience in a relevant discipline. The appointment will be made on the 1B or 1A scales (£9,816 to £11,088 p.a. + £1650 L.A.) depending upon qualifications, age and experience. Applications including a CV and the names of two referees should be sent by 20th October to **Dr Alan Johnston, Dept. of Psychology, University College London, 26 Bedford Way, London, WC1 0AP,** from whom further details may be obtained Tel. 01-387 7050 xt 5380.

Equal opportunities Employer (1708)A

JOHN INNES INSTITUTE
Plant Molecular Virology

A Higher Scientific Officer position is available to study the interactions between the aphid transmission helper protein of cauliflower mosaic virus, the virus particles and the aphid vector. The project will involve the expression of the helper protein in eukaryotic systems, biological and molecular biological analysis of its function and physical analysis of its structure. Applicants should have experience in molecular biology. Further details are available from Dr R. Hull.

This is a period appointment and will be to the HSO scale £10,026 to £13,460 Non contributory superannuation. Equal opportunities employer.

Applications with full cv and the names of two referees should be sent to the Personnel Officer, John Innes Institute, Colney Lane, Norwich, NR4 7UH to arrive not later than (3 weeks after date of insertion). VIR/381.

The John Innes Institute is associated with the AFRC Institute of Plant Science Research. (1711)A

SURFICIAL PROCESSES

University of Wyoming

The Department of Geology and Geophysics invites applications for a tenure-track position at the assistant or associate professor level in the broad field of surficial processes. We are seeking a creative scientist who uses quantitative methods to study fundamental problems and who demonstrates the potential for developing new research directions. We are particularly interested in people whose work relates to global climate, environmental geosciences, or chemical or isotopic hydrology, but outstanding candidates in any field of Quaternary geology will be considered. The department has 21 faculty, about 100 graduate students and a strong undergraduate program. We have active research programs in sedimentary basin analysis, environmental geochemistry, remote sensing, hydrology, and crustal evolution. In addition, the University has a strong emphasis on interdepartmental multidisciplinary projects The successful candidate is expected to teach at the graduate and undergraduate level, supervise graduate students, and establish a vigorous research program. PhD is required Interested persons should send a resumé, a statement of research interests, and the names and addresses of at least 3 references to **Dr. James I. Drever, Search Committee Chair, Dept. of Geology & Geophysics, University of Wyoming, Laramie, WY 82071.** Closing date for applications is December 1, 1989. The University of Wyoming is an affirmative-action/equal-opportunity employer. We strongly encourage applications from women and minorities (NW4311)A

POSTDOCTORAL POSITIONS IN IMMUNOLOGY

The Department of Immunology has immediately available postdoctoral positions for training in molecular and cellular immunology. Individual projects are concerned with the host response to viruses and autoantigens, lymphocyte ontogeny, immunodeficiency disease and macrophage biology. The faculty comprises: J. E. Allan, A. R. Brown, C. Coleclough, M. E. Conley, P C. Doherty, M. Fishman, J. L. Hurwitz, D. W. Metzger, D. Sun and W. S. Walker.

St. Jude Children's Research Hospital is a multidisciplinary biomedical research institution providing many opportunities for collaborative interactions with, in particular, strong programs in molecular virology, tumor biology, clinical oncology and growth factors. Annual salary is at least $22,000 and there is an excellent benefits package.

Applications and informal inquiries:

Dr. Peter C. Doherty
Department of Immunology
St. Jude Children's Research Hospital

PHLS CENTRE FOR APPLIED
MICROBIOLOGY &
RESEARCH
DIVISION OF
BIOTECHNOLOGY
require a
MOLECULAR GENETICIST

A research scientist is required to join a team actively engaged in the application of recombinant DNA methodology to *Clostridium* spp. of medical and industrial importance Current research includes: optimisation of gene transfer technology; genetic analysis of fermentative pathways; manipulation of genes involved in substrate utilisation; vaccine production and: DNA probe development for toxinogenic species.

The successful candidate should hold a degree, or equivalent, in a biological discipline. Practical experience in a relevant area would be an advantage.

Graduate scientists seeking registration for a higher degree would not be discouraged.

Dependent on research experience, appointments will be made on either the BGM £7,378-£11,073 or SGM salary scale £11,778-£15,394 (under review).

Candidates seeking further information should contact Dr N P Minton, telephone: (0980) 610391 ext 562.

Application forms can be obtained from the Personnel Officer, PHLS Centre for Applied Microbiology and Research, Porton Down, Salisbury, Wiltshire SP4 0JG, tel: (0980) 610391 ext 240, to whom completed forms should be returned, together with a curriculum vitae and the names of two academic referees by 13th October 1989 quoting Post No. 0923.

FELLOWSHIPS

EMBL

EUROPEAN MOLECULAR BIOLOGY LABORATORY

PhD Programme in Molecular, Cellular, Structural and Computational Biology

The European Molecular Biology Laboratory will award predoctoral fellowships in 1990 for University graduates wishing to study for a PhD at EMBL Heidelberg, Federal Republic of Germany, or at the EMBL Outstations in Hamburg, FRG, and Grenoble, France. Areas of study include. **Biocomputing** (theory and analysis of protein structure and genomic sequence information, development of computer methods for molecular biology), **Biological Structures** (structural analysis of membrane proteins and assemblies, nucleic acid-protein interactions and cytoskeletal and muscle proteins), **Cell Biology** (protein and membrane traffic, membrane biogenesis, post-translational modifications, functional aspects of the nucleo- and cytoskeleton), **Differentiation** (oncogenes, growth factors and growth control, haemopoietic cell differentiation, developmental and tissue-specific gene expression), **Gene Expression** (regulation of gene expression at the transcriptional and post-transcriptional level, protein engineering, structure and function of small RNAs) and **Instrumentation** (technical innovations relevant to molecular, cellular and structural biology). At the **Outstations,** biological structures and dynamics are studied using the specialised techniques of synchrotron radiation (Hamburg) and neutron diffraction (Grenoble).

To be eligible, candidates must hold, or anticipate receiving in 1990, a first or upper second class honours degree, a masters degree, a diploma or equivalent in biological sciences, physical sciences or mathematics.

Candidates must be citizens of the member states of EMBL or EMBC namely: Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland or the United Kingdom.

The deadline for receipt of completed applications is December 31, 1989. Successful candidates will be notified by the end of March 1990. Those awarded predoctoral fellowships will be expected to begin working at EMBL in 1990. The normal duration of the fellowships will be 3½ years.

Application forms and a brochure giving further information about the research at EMBL and the groups participating in the Laboratory's PhD programme are available on request from: **Dean of Graduate Studies, EMBL, Postfach 10.2209, D-6900 Heidelberg, Federal Republic of Germany.**
(W6530)E

Roche Institute of Molecular Biology

GRADUATE FELLOWSHIPS

The Roche Institute of Molecular Biology is pleased to announce a joint graduate program with the Department of Biological Sciences at Columbia University. Selected students will complete their thesis research at the Roche Institute while academic requirements will be fulfilled under the supervision of the Department of Biological Sciences at Columbia. Upon completion of the program, students will receive a PhD degree from Columbia University

The Roche Institute of Molecular Biology, founded in 1967, is dedicated to basic research in emerging areas of molecular biology Staff members enjoy complete independence in their choice and pursuit of research problems The Institute is located in suburban New Jersey, approximately 10 miles west of Manhattan, making it readily accessible for lectures and courses at Columbia University and other educational centers in New York City

Fellowships include stipend and paid tuition Applications must be received by January 1 to be considered for the following academic year

For further information and application form, contact· **Administrative Office, Roche Institute of Molecular Biology, Nutley, New Jersey 07110; (201) 235-3681.**

SITUATIONS VACANT continued 25, 28 and 30

RESEARCH FELLOWSHIP

Girton College Cambridge

Applications are invited for a Research Fellowship open to graduates of any university for research in a scientifc subject The Fellowship is tenable for three years from 1 October 1990. The applications should be in the fields of Mathematics, Natural Sciences, Geography and allied subjects.

The emolument of the Fellowship is reviewed annually. From 1 October 1989 the stipend for a person who has not completed a Ph.D. is £6,850 per annum; for a person with a Ph.D., £9,000 per annum rising by two increments to £9,300 per annum. Financial support from other sources may be taken into account.

The Fellowship, at the wish of the Fellow, may be pensionable under USS. Residence is provided, if required; a charge of £85.40 a month is made towards residence, and Commons (i.e. meals) are free of charge. If the Research Fellow is married, and lives out, there is a living out allowance of £1,100 p.a. A child allowance of £250 per annum for the first child is made. Research Fellows may, if they wish, be permitted to teach up to six hours per week. Research expenses of £750 over the three years may be claimed for approved special expenses.

Applications *(4 copies)* on a form which may be obtained from the **Secretary to the Council, Girton College, Cambridge CB3 0JG,** must be returned to her not later than *24 October 1989.* A statement of approximately 1000 words outlining the work candidates wish to submit in support of their applications and the research they propose to do if elected, will be required at the same time as the application is returned. The applicant should also include a short resume of his/her research for an informed layman. If the applicant is short-listed he/she will be asked to submit work in support of the application immediately after October 31st 1989; it is suggested that the work to be submittted should be a dissertation and/or other writings. If the work in support of the application has not been received within 14 days, the Electors will not consider the application further.

Since the College is advertising for a Research Fellow in the Arts at the same time Science applicants should state when writing for an application form whether their subject of research is an Arts or a Science subject. (1705)E

UNIVERSITY OF WARWICK
DEPARTMENT OF BIOLOGICAL SCIENCES

POSTDOCTORAL FELLOW

A Postdoctoral Research Fellowship, funded by the Gas Research Institute of Chicago for up to three years, is available immediately. The research project involves a detailed study of the mechanism of action of methane monooxygenase. The successful applicant will join a multidisciplinary research team working on the biochemistry, physiology and molecular genetics of methane oxidation. A knowledge of molecular biology and site-directed mutagenesis techniques would be advantageous.

Salary will be on the Research IA scale: £10,458 to £16,665 p.a Further details about the project may be obtained from Dr J C Murrell (0203 523553) or Professor H Dalton (0203 523552) (direct lines). Application forms from the **Executive Officer, Department of Biological Sciences, University of Warwick, Coventry CV4 7AL,** quoting Ref. No. GRI/BS332/14. Closing date: 19 October 1989.

AN EQUAL OPPORTUNITIES EMPLOYER. (1663)E

POSTDOCTORAL FELLOW

Applications are invited for an NIH supported postdoctoral fellowship in research studying the polyamine-dependence of gastro-intestinal mucosal proliferation and differentiation. Experiments involving the cell biology of these processes are performed in both whole animals and epithelial cells in culture. For representative publications see American Journal of Physiology 256:G342, 1989, 256 G1049, 1989 and 257:G145, 1989. There is no citizen restriction on this position. The position is available for 2 to 3 years.

Send an application letter, curriculum vitae and names of references to. **Edward R. Seidel, Ph.D., Department Physiology, East Carolina University School of Medicine, Greenville, NC 27858.**

An Equal Opportunity/Affirmitive Action Employer Federal Law requires proper documentation of identity and employability at the time of employment It is requested that this documentation be included with your application. (NW4292)E

UNIVERSITY OF SOUTHAMPTON
Department of Chemistry

POSTDOCTORAL RESEARCH FELLOW

Design and Synthesis of DNA-Binding Oligopeptide

Applications are invited for an SERC-funded postdoctoral research fellowship work on the design and synthesis of DNA-binding oligopeptides, in collaboration with Drs. N G J Richards (Chemistry) and K R Fox (Physiology/Pharmacology). This project is in an area at the interface of biology and chemistry, and will involve the construction of linear peptides containing both natural and non-natural amino acids which can adopt well-defined solution phase conformations. The ability of these materials to interact sequence-specifically with double-stranded DNA will then be investigated. Infrastructure for the project includes a well-equipped peptide laboratory, facilities for DNA preparation, access to a 500 MHz n.m.r. spectrometer and an advanced molecular graphics unit.

Starting salary will be on the Grade IA scale (£10,458-£16665) based upon age and experience, and will be available from 1 October 1989. Initially the position is for 1 year, but can be extended to a 3 year appointment.

Please send formal applications, including C.V. and the names of two referees to either **Dr N G J Richards, Department of Chemistry, The University, Southampton, SO9 5HN, or Dr K R Fox, Department of Physiology and Pharmacology, School of Biological Sciences, Boldrewood, Bassett Crescent, Southampton, SO9 5NH.** Informal enquiries can be made by calling 0703-593598 or 0703-595000, ext. 4374. Please quote reference number 75/JAD/nvs. (1669)E

POST-DOCTORAL FELLOWSHIP

To join a multi-disciplinary research group working on structure-function relations in small intestinal brush border membrane and fat absorption into this membrane. The work includes biophysical studies of membrane properties, the isolation and purification of membrane bound enzymes and proteins. The emphasis will be on protein chemistry.

Previous experience in protein chemistry, particularly in the methodology of protein chemistry, particularly in the methodology of protein isolation and purification and the production of antibodies would be an advantage. Initially the appointment will be for two years, an extension for a third year is possible. Applications including a curriculum vitae and names of two referees should be sent to the address below.

Prof. Dr. H. Hauser, Laboratorium für Biochemie, Universitatsstrasse 16, **ETH-Zentrum,** CH-8092 Zurich, Switzerland.

(W6523)E

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF PURE AND APPLIED CHEMISTRY

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a 3 year SERC-funded Postdoctoral Research Fellowship to work on a joint project with Dr. R Wolf of the Imperial Cancer Research Fund Laboratory at Edinburgh University on transition metal proteins and analogues, using surface enhanced resonance Raman scattering (SERRS) to probe the structure/function relationships in cytochrome P-450. Experience in Raman spectroscopy or in P-450 separation will be an advantage. Salary: in range £10,458-£16,665 per annum.

Applications (Ref: R72/89) with full CV and the names and addresses of three referees should be sent to **Professor W E Smith, Department of Pure and Applied Chemistry, Glasgow G1 1XQ** by 30 November 1989. (1667)E

Wayne State University

Predoctoral Fellowships
Wayne State University

Positions are available for graduate study leading to a Ph D. in Physiology. An annual stipend of $11,500 plus tuition waiver and medical insurance are provided for qualified students.

The department has strong research programs in molecular cellular and systems physiology Specific areas of interest protein structure and function, cardiovascular and renal physiology.

For more information, write to **Dr. Lowell McCoy, Graduate Officer, Department of Physiology, Wayne State University School of Medicine, 540 E. Canfield, Detroit, MI 48201 USA.** *WSU is an EOE/AAE*

POSTDOCTORAL FELLOWSHIPS

LINCOLN COLLEGE

(University from 1990)

Applications are invited from suitably qualified candidates for the following fellowships:

89/41: The Canterbury Frozen Meat Company Ltd established a fellowship to mark its centenary in 1982 in fields which should contribute to the continued development of New Zealand agriculture and the meat industry.

Intending applicants should draw up a research proposal in conjunction with the appropriate head of department in one of the following areas:

Agricultural Microbiology and Biochemistry, Animal and Veterinary Sciences, Entomology, Plant Science, Soil Science or Wool Science.

The emolument for this fellowship is at the rate of $NZ30,000 per annum, part of which will be available for fares. Tenure is for one year.

89/43: The University Grants Committee has funded a fellowship in the Animal and Veterinary Sciences Group. The project will analyse aspects of the defence mechanisms used by sheep to reject helminth parasites and is part of ongoing research in this area of parasitology. Applicants with experience in conducting immunological assays, the generation of monoclonal antibodies, tissue culture, protein and/or nucleic acid biochemistry would be preferred.

The emolument is at the rate of $NZ35,000 per annum Tenure is for two years.

Enquiries may be made to Professor A.R Sykes, or Dr R.G McFarlane, phone (64)(03)252811 or electronic mail MCFARLAN@LINCOLN AC. NZ

Applicants should have completed the requirements for the award of the degree of Doctor of Philosophy and be less than 35 years of age.

Further details including conditions of appointment and method of applications are available from the undersigned. Applications close 30 November 1989 Lincoln College is an equal opportunity employer

A R Donithorne, Acting Registrar, P.O Box 94, Lincoln College, Canterbury, New Zealand. (W6353)E

Max-Delbrück-Laboratorium
in der Max-Planck-Gesellschaft, Köln, FRG

Fellowship available for:

Postdoc or PhD — Student

to work on the physiological and developmental function of the rosi proteoncogene, a receptor-type tyrosine-specific protein K inase, and the elucidation of the involvement of rosi in the etiology of glioblastomas using transagenic mice.

Applications with research interests, C.V. and names, addresses and phone numbers of 2 referees should be sent to: **Dr. Carmen Birchmeier, Max-Delbrück-Laboratorium in der MPG, Carl-von-Linne-Weg 10, 5000 Koln 30 FRG,** phone: 0221 5062 483/Fax: 0221 5062 319. (W6363)E

UNIVERSITY OF CAMBRIDGE

OPPENHEIMER RESEARCH FELLOWSHIP

Applications are invited for an Oppenheimer Research Fellowship in the field of colloid science and surface chemistry, including applications to metallurgical reactions. Fellowship is tenable for three years in a physical or biological science department, commencing 1 October 1990, when applicants should be under the age of 30. Stipend ranges from £10,460 (age 24) to £15,375 (age 32). Contributions towards research expenses and removal from overseas. Applications (10 copies) to Miss M.I. Johnston, Department of Earth Sciences, University of Cambridge CB2 3EQ by 31 January 1990, including curriculum vitae, list of publications, statement of 1,000 words each of current research and proposed programme, names and addresses of two referees, and written approval to the Head of the Department in which it is hoped to work (1727)E

STUDENTSHIPS

UNIVERSITY OF LIVERPOOL
DEPARTMENT OF HAEMATOLOGY

University of Liverpool Research Fund Postgraduate Studentship

Applications are invited from suitably qualified graduates in biochemistry, cell biology or related disciplines

The work will involve investigation of the impact of clinically important cytokines on bone marrow function in-vitro In particular, the cellular and molecular effects of cytokines on bone marrow stroma from normal and leukaemic marrows will be studied

The student will enrol for a PhD

Please contact **Dr. D.W. Galvani tel 051-709 0141 ext 2811, Department of Haematology, The University, P.O. Box 147, Liverpool, L69 3BX.** (1717)F

BIRKBECK COLLEGE
(University of London)

CRC PhD Studentship-Metallo-anticancer agents

Applications from those holding a good class honours degree are invited for a 3-year Cancer Research Campaign research studentship in a group working on the synthesis and biological chemistry of novel metal complexes as anticancer agents.

Applications including a CV and the names of 3 referees should be sent to the **Assistant Secretary (Personnel), Birkbeck College, Malet Street, London, WC1E 7HX.** Telephone: 631 6529. Closing date: *17 October 1989.* (1666)F

FELLOWSHIPS

STA FELLOWSHIPS

Postdoctoral Fellowships in Japanese Government Laboratories

The Japanese Science and Technology Agency (STA) is offering postdoctoral fellowships to scientists and engineers of the countries listed below for periods of 6 months to 2 years to be held in any Japanese national laboratory (excluding university and university-affiliated laboratories). Over one hundred Japanese research laboratories covering almost all areas of science, engineering and medicine are participating in the scheme.

The fellowships are open to young PhD holders of under 35 (although older researchers will be considered) from universities, research councils, government research laboratories and industry. Any science or engineering discipline will be considered except military R & D. Applicants will be required to supply a letter of invitation from their Japanese host institution (the organizations listed in Table 1 provide help in contacting suitable host institutions).
Those in the final stages of a PhD may also apply.

There are no closing dates but candidates are encouraged to submit their applications as soon as possible. Fellowships for fiscal 1989 must be taken up by March 1990.

FELLOWSHIP AWARDS

Fellowships include round-trip air tickets (economy class) and the following tax-free allowances:

1) Living allowance: ¥270,000 (about US$2,000) a month
2) Family allowance: ¥ 50,000 a month
3) Housing allowance: up to ¥100,000 a month
   Apartments will normally be provided to awardees. The apartment floor area is 40 m^2 for awardees unaccompanied by their family and 60 m^2 for awardees to stay with their family in other than metropolitan areas such as Tokyo. If an awardee prefers to use a larger apartment because of the family size or otherwise ¥100,000 maximum per month may be paid as housing allowance; any shortfall is to be borne by the awardee.
4) International relocation allowance: ¥200,000
5) Travel allowance: ¥100,000 a year
   (within Japan)
6) Japanese language lesson courses are to be provided free of charge to the STA Fellowship awardees and their family members in Tsukuba area. Those who live in places other than the Tsukuba area will be entitled to reimbursement of Japanese language school tuition up to a specified amount.
7) Excursions or the like will be held to help make the Fellowship awardees and their family members in Tokyo/Tsukuba areas familiarized with Japan's culture, tradition and history.

In addition, ¥1,480,000 per year will be paid to the host institute to cover research costs and insurance for researchers will be paid by JISTEC during their stay in Japan to cover medical care.

APPLICATION PROCEDURE FOR STA FELLOWSHIP

Management of the STA Fellowship, including recruitment of candidates, is entrusted to the Japan International Science and Technology Exchange Center (JISTEC).

Responsible organizations overseas which represent the governments of their respective countries are given in Table 1.

A researcher wishing to be awarded the STA Fellowship should apply to the responsible organization in his/her country. Candidates are required to contact the desired host institute and obtain a letter of acceptance before filling an application with their government. Further information regarding the STA Fellowship and host Institutes is available from the responsible organizations.

A researcher whose country is not listed in Table 1 could contact a Japanese host institute directly, which in turn may recommend the reseacher to JISTEC as a candidate for STA Fellowship.

Fig. 1 shows the process from consult/contact to receipt of award. (W6352)E

CYSTIC FIBROSIS RESEARCH TRUST

Call for Grant Applications

In response to the cloning of the Cystic Fibrosis gene (Science, 8 September 1989) the Cystic Fibrosis Research Trust is requesting applications for directed grants to produce reagents (antibodies, cell lines, DNA probes, etc.) for studying the biochemistry and genetics of Cystic Fibrosis. There is no specific deadline for applications and proposals will be considered within one month of receipt. The grants will be normally for a period of 1 year.

Long term grants will be considered under the usual guide lines with the next deadlines being 15 November 1989.

Please apply in writing to:—

The Director,
Cystic Fibrosis Research Trust,
Alexandra House,
5 Blyth Road,
Bromley, Kent, BR1 3RS.

RESEARCH GRANTS

from

The Erna and Victor Hasselblad Foundation

The Erna and Victor Hasselblad Foundation will award grants for the year 1990 in order to promote scientific research and education in the field of natural science and photography.

Application for grants should reach the Foundation not later than January 31, 1990. Application forms may be obtained from the Foundation. Applications received after the above date will not be considered.

For the year 1990 SEK 8.000.000 (GBD 800.000) is available for distribution. According to the statutes of the Foundation large projects will in the first place be considered for grants. Grants which are not concentrated on salaries are given priority. In principle medical projects will not qualify for grants.

Grants awarded are expected to be paid out before the end of June 1990.

National Institutes of Health

POSTDOCTORAL POSITION

A postdoctoral position is available immediately for in-vitro study of receptor and post receptor mechanisms involved in the pathogenesis of HIV induced dementia. The applicants should be legal U.S. residents and should have obtained a Ph.D. degree within the last three years. Background in protein chemistry and/or receptor biochemistry or second messenger pathways is desirable. Work with infectious HIV will not be involved. Reply with curriculum vitae and three references to:

Drs. George Kunos or Laszlo Takacs
Laboratory of Physiologic and Pharmacologic Studies
National Institute on Alcohol Abuse and Alcoholism
National Institutes of Health
12501 Washington Avenue
Rockville, MD 20852.

NIH is an equal opportunity employer.

AWARDS

Sarstedt-Research Prize 1990

The German Society for Clinical Chemistry awards the Sarstedt Research Prize 1990.

The prize of 50.000, — DM is donated by Sarstedt, Nümbrecht, for outstanding and novel work in the field of clinical chemistry and chemical pathology, haematology, blood coagulation and instrumental analysis, related to the development of diagnostic methods in the field of early diagnosis of diseases.

Competitors for the 1990 prize should submit papers concerning one theme, either published or accepted for publication between Jan. 1st, 1988 and Jan. 1st, 1990, before Jan. 15th 1990 to

Prof. Dr. H. Greiling
Secretary of the Sarstedt-Research Prize
Inst. of Clinical Chemistry and Pathobiochemistry
University of Technology (RWTH) Aachen
Pauwelsstraße 30, D-5100 Aachen (W6532)N

Request for Applications

Cystic Fibrosis: From Gene to Basic Defect

The Cystic Fibrosis Foundation invites investigator-initiated research grant applications to extend information from the newly discovered cystic fibrosis (CF) gene to the specific cellular defects observed in CF.

Recent evidence suggests that the CF gene codes for a transmembrane protein involved in the control of cellular transport events. This work complements previous findings on abnormal ion transport in CF. Research areas responsive to this request include, but are not limited to:

- *Identification of the biochemical/ physiological events related to the defective ion transport seen in CF;*
- *Development of appropriate model systems for studying the regulation of defective cellular processes;*
- *Development of pharmacological agents or other therapies to reverse the abnormal phenotype observed in CF cells.*

Research approaches and model systems must be directly relevant to understanding the basic defect in CF. **Applicants may request up to three years of support.** Level of support will be commensurate with the scope of the proposed project.

The deadline for receipt of applications is December 1, 1989. For further information and applications, interested individuals are urged to contact Dr. Robert J. Beall or Ms. Dale Glass at the Cystic Fibrosis Foundation.

SEMINARS & SYMPOSIA

SWISS INSTITUTE FOR EXPERIMENTAL CANCER RESEARCH

25TH ANNIVERSARY SYMPOSIUM

NOVEMBER 23rd AND 24th 1989, AUDITOIRE CESAR ROUX, CENTRE HOSPITALIER UNIVERSITAIRE VAUDOIS, LAUSANNE

CANCER RESEARCH TODAY

Recent progress in the major areas of fundamental cancer research will be presented by the following main speakers.

B. AMES, *Berkeley*
M. BARBACID, *Princeton*
B. GRIFFIN, *London*
P. HOWLEY, *Bethesda*
D LANE, *London*
R. SAGER, *Boston*
R. SCHIMKE, *Stanford*
J P. THIERY, *Paris*
M WATERFIELD, *London*
P. WELLAUER, *Lausanne*
C.WEISSMANN, *Zurich*

A poster session will be held in addition to the oral presentations

Organizers: P. Beard and H. Diggelmann, Swiss Institute for Experimental Cancer Research, 1066 Epalinges, Switzerland.

Registration. Participants must register before Oct. 20, 1989, at the following address: Ms Sophie Cherpillod, Swiss Institute for Experimental Cancer Research, 1066 Epalinges, Switzerland, Telefax 021/326 933, Telex 450 156 ISRCCH. No registration fee is required A detailed program will be sent to registered participants.

Hotel reservation. Please make your own arrangements through the Lausanne Tourist Office and Convention Bureau, 2, av de Rhodanie, Box 248, CH-1000 Lausanne 6, Telephone 021/27 14 27, Telefax 021/26 86 47, Telex 454 833 (W6358)M

LECTURES

LEUKAEMIA RESEARCH FUND
1989 GUEST LECTURE

will be delivered on Wednesday 22nd November 1989 at 5.30pm at the Jarvis Lecture Theatre, 66 Portland Place, London W1 by Professor Sir David Weatherall, FRS
Nuffield Professor of Clinical Medicine
University of Oxford

Subject
"THE MOLECULAR BASIS FOR THE CLINICAL VARIABILITY OF GENETIC DISEASE"

Tickets, at no charge, will be issued from September, Please apply to.
LEUKAEMIA RESEARCH FUND
43 Great Ormond Street, London WC1N 3JJ
Tel: 01-405 0101 (1704)K

ASSISTANTSHIPS

UCL

CELL CYCLE CONTROL GENES IN HIGHER PLANTS

Applications are invited for a postdoctoral research assistantship in a recently established AFRC Link Group between the Department of Biology, University College London and the John Innes Institute, Norwich. The position is for 3 years and will involve the identification of higher plant homologues of yeast cell cycle control genes. Salary will be in the range 10,458-11,736 plus 1,650 London weighting. A strong background in molecular cell biology, biochemistry or related discipline would be an advantage Applicants should send a curriculum vitae including the names of two referees to **Dr D J S Hyams, Department of Biology, Darwin Building, University College London, Gower Street, London WC1E 6BT,** from whom further information may be obtained (Tel: 01-380 7343)
Equal opportunities Employer (1709)P

University of Dundee
Department of Biochemistry

Research Assistantship in Plant Molecular Genetics

A three year AFRC-funded position which involves the cloning of retrovirus-related transposons from potato is available. The study will primarily be carried out in the Department of Biochemistry (which was recently given a top rating, along with only three other biochemistry departments in the country, for its research excellence) and will be carried out in close collaboration with the Scottish Crop Research Institute at Invergowrie, which is the major UK centre for genetic studies of the potato.

Starting salary up to £10,458 on the 1A/1B Scale (£9,816–£16,665).

The project will also involve collaboration with the Institut National de la Recherche Agronomique in Versailles, France The position is available at the Postdoctoral level but suitable predoctoral candidates should not hesitate to apply; in the latter case the research would be expected to lead to a Ph.D. The position can commence immediately or can be delayed as long as is necessary

For further details, please contact Dr A.J. Flavell, Department of Biochemistry. Tel: (0)382-23181

Applications, including C.V. (2 copies) and the names of 2 referees, should be sent to the **Personnel Office, The University, Dundee DD1 4HN, Scotland, UK.** Please quote Ref. EST/438/89 (1691)P

UNIVERSITY OF STRATHCLYDE
Chemistry of Monocytes in Rheumatoid Arthritis

RESEARCH ASSISTANTSHIP

Applications are invited from graduates in Chemistry or a biological science for a 3 year Research Assistantship, funded by the Arthritis and Rheumatism Council, to work on an interdisciplinary project supervised jointly by Dr. Sturrock of the Department of Medicine, University of Glasgow, and Professor Smith and Dr. Reglinski of the Department of Pure and Applied Chemistry, University of Strathclyde The work covers the use of new Receptor sites to modulate monocyte function, using new spectroscopies, including NMR, capable of following the chemistry of individual reactions to living cells

Salary: in range of £9,816-£12,381 per annum
